Exhaustive tests with oxy-acetylene burners for metal cutting regarding pressure loss between reducing valve and burner, oxygen consumption under different operating conditions, and cutting groove were made systematically on ordinary wrought iron plates of 16, 30, and 50 mm. thickness. Straight cuts 600 mm. in length were made and the flame adjusted to a consumption of 200 l. of acetylene/hr. The oxygen used in these tests had a purity of 99.0–99.1%. The whole arrangement and the apparatus are described in detail. The results illustrated by a great number of tables, curves and microphotographs have shown the following facts: (1) The oxygen consumption/unit length of cut depends mainly on the diameter of the burner nozzle; for the same cutting velocity, the oxygen consumption is less for small nozzles and high pressures of oxygen than for large nozzles and low pressures. (2) Within the limits used in practice, the cutting velocity has only slight influence on the specific oxygen consumption for cutting. (3) The cutting velocity can be increased both by increase of the oxygen pressure and by the use of larger cutting nozzle. (4) In order to cut economically, it is not sufficient to attempt to obtain the lowest possible oxygen consumption; it is rather necessary to also take into account the cost of heating gas (acetylene) and wages. These 2 factors become smaller for increased cutting velocity. It is, therefore, often advisable to use a larger nozzle in spite of its higher oxygen consumption because the saving in wages and cost of acetylene are greater than the higher costs for oxygen. In addition to the above-mentioned factors, the economy of cutting depends upon the purity and humidity of the oxygen, kind of heating gas, size and type of flame, etc. (5) The tested burners and valves showed considerable pressure losses between reducing valve and burner nozzle for large flows of oxygen. In the construction of cutting burners, care should, therefore, be taken that the passages for oxygen have sufficiently large sections and no sharp curves. (6) The width of the cutting groove increases with the size of the nozzle, increase of oxygen pressure, and distance of nozzle from surface of material. The illustration shows the cost for 1 mm. cutting length as a function of diameter of nozzle pressure and cutting velocity for a 30 mm. wrought iron plate. For the calculation of costs, a price for oxygen of RM 0.40/m.³, of acetylene of RM 2.65, and wages and overhead of RM 2.0 has been assumed. Ha(11c)

The Welding Shop of the Verband für Autogene Metallbearbeitung Branch Mannheim-Ludwigshafen (Die Schweisswerkstätte der Ortgruppe Mannheimludwigshafen). H. Tuergens. *Schmelzschweissung*, Vol. 10, Jan. 1931, pages 1–3.

Description of the school where welding courses are given. 30 pupils can be instructed at one time. Ha(11c)

Quick Spot-Welding Machine. (Schnell - Punktschweiss - machine.) Stuemer. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 22, 1930, page 1616.

Brief information on a machine to be used for quantity production with particularly large transformer to develop great local instantaneous heating. Ha(11c)

A Training Course for Arc Welders. Parts I–II. Samuel Martin, Jr. *Welding*, Vol. 1, May 1930, pages 464–467; June 1930, pages 525–527, 542.

Because of the rapid increase in the use of arc welding, the available supply of first-class operators for arc welding equipment has never been adequate to the demand. It is a good investment to maintain a training course or to send employees to a welding school, for good operators return large dividends in actual production, in addition to obtaining maximum usage from invested capital. Discusses planning the course, essential equipment, additional equipment for larger schools, qualifications for instructor, selecting students, training course, procedure common to each lesson. Outlines a course of 40 lessons to be performed, one a day. Includes a table of welding characteristics of various special and alloy steels. W(11c)

Hard Surfacing with Oxy-Acetylene Welding Torch. Miles C. Smith *Welding*, Vol. 1, May 1930, pages 458–461.

Discussion of desirable prerequisite knowledge, manner of procedure and limitations of application of hard facings. W(11c)

Compression Rods for Welded Structures (Knickstäbe für geschweisste Bauten). Karl Melcher. *Schmelzschweissung*, Vol. 10, Jan. 1931, pages 9–12.

The introduction of welding has made possible the joining of profiles or structural shapes which could hardly be joined by riveting or bolting. The paper investigates different sections with regard to their suitability for welding and gives comparative results for angle-irons, U-irons, and semi-circular and full pipes and illustrates with examples. As a particularly useful and strong combination is mentioned 2 channels welded with their short flanges against a flat plate, thus forming a kind of hollow pillar. This combination sometimes results in a saving of 50% of the weight. Ha(11c)

Oxy-Acetylene Cutting of Structural and Alloyed Steels (Ueber das autogene Schneiden von Baustählen und legierten Stählen). *Communication from the Research Laboratory of the "Works Autogen" of the I. G. Farbenindustries A.-G.—Frankfurt a.M. Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 5, 1930, pages 25–54.

This research was undertaken to clear up several questions with reference to the influence which oxy-acetylene welding has on the cutting edges of the material. From the test results which are given in tables and illustrated by many photographs, it could be concluded that the nature of the surface of the cut after cutting (whether more or less smooth) is of much greater importance than the transformations in the material because the latter represents rather a refining of the material by heat treatment; a subsequent machining by drilling, planing, etc., might destroy all this improvement. The reports recommended, therefore, that no objection need be raised against oxy-acetylene cutting even in cases where, so far, usually other mechanical means have been specified, such as in boiler manufacture, shipbuilding, etc. The appearance of the surface gives a good index to the quality of the cut. The manufacturing cost can usually be materially reduced. Ha(11c)

Psychological Tests of Acetylene Welders (Psychotechnische Untersuchungen der Acetylenschweisser). P. Tulacz. *Schmelzschweissung*, Vol. 10, Jan. 1931, pages 7–8.

This paper was read at the Tenth International Acetylene Congress in Zurich, 1930, and discusses methods and tests to determine whether a man (1) is fit to be a welder; (2) is fit for a particular, especially difficult kind of work. Optical and mental qualities required and the tests to determine them were discussed. Tests, however, will still have to be developed for obtaining reliable judgments. Ha(11c)

Mixing of the Gases in the Oxy-acetylene Welding Burner (Mischung im Azetylene-Sauerstoff-Schweissbrenner). E. Streb. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*. Series 5, 1930, pages 93–99.

The question of homogeneity of the gas mixture in oxy-acetylene burners is solved by the flow of the gases in the burner tube, by the chemical analysis of the gas mixture in the section of the mouth, by the ignition velocity at the mouth of the burners, and by the welding output. The results of these investigations permit the conclusion that the mixture escaping from the burner is, in all systems, homogeneous. The ignition velocity for different mixture of acetylene and oxygen never becomes greater than the escaping velocity at the mouth of the burner. Ha(11c)

Symposium of Weld Testing Establishes Important Facts. *Iron Age*, Vol. 126, Dec. 4, 1930, pages 1680–1681, 1698.

Held at fall meeting of the American Welding Society. Committee on standard tests of the Bureau of Welding decided that standards adopted in 1921 need revision to provide standardized and simpler procedures for various mechanical tests in connection with needs. Three standard tests proposed as reliable: Tension, bending and shear. Endurance limit usually $^1/_3$ of tensile strength of weld. Gamma ray from radium suitable for examining welds up to 12 in. VSP(11c)

Heavily Coated Electrode for Quality Welding. *Electrical World*, Vol. 97, Mar. 28, 1931, page 616.

The General Electric Co. has marketed an electrode composed of 0.13–0.18% carbon steel covered with a heavy coating of cotton braid impregnated with an arc stabilizing flux and is available in diameters from $^1/_8$–$^3/_8$". Metal deposits of this electrode will have a high tensile strength and will produce a homogeneous structure resulting in a ductile weld. Extreme arc stability and high arc voltages permissible produce an unusually high speed of welding for certain applications. WHB(11c)

A number of illustrations show different types of electric welding in various applications. WHB(11c)

The Quality of Materials for Fusion Welding. C. R. Texter & F. M. Speller (National Tube Company). *Preprint, American Society for Testing Materials*, Mar. 1931, 8 pages.

While welding is most often performed on steel with C not over 0.30%, higher C material, and even intermediate Mn rail steel can be welded, open-hearth steel is generally preferred to Bessemer for welding. Steel that is laminated, due to too small a top crop, may give trouble. In general, welding equipment, fluxes and technique can be chosen to handle almost any material it is desired to weld, and these are of more importance than the composition of the material. Various specifications for material to be welded and for welding rod and filler are cited. HWG(11c)

Resistance Welded Pipe. Ernest E. Thum. *Metal Progress*, Vol. 1, Sept. 1930, pages 33–37.

The development of this latest method of manufacturing pipe is traced. The steps in the process and the testing methods are discussed. WHK(11c)

Welding in the Steel Foundry. I. H. Namack & H. C. Hobart. *Metal Progress*, Vol. 1, Oct. 1930, pages 71–74.

The advantages of fabricating complicated shapes difficult to cast in one piece by the welding of simpler castings is described. WHK(11c)

Canada's First Large Arc Electric Welded Steel Structure Erected. H. B. HANNA. *Iron & Steel of Canada*, Vol. 13, Dec. 1930, pages 271–274.

A complete description, illustrated by 11 photographs, of a new addition to the Peterboro plant of the Canadian General Electric Company. The building has a floor area of 72,000 ft.², the bays being 80 ft. wide, and the columns spaced 25-foot centers. The steel frame weighs approximately 960 tons. It is interesting to note that the lowest breaking stress attained by any welder working on this building was 12,250 lb./linear inch for $^3/_8'' \times {}^3/_8''$ fillets. OWE(11c)

Resistance Control. Thyratron Control Equipment for High-Speed Resistance Welding. R. C. GRIFFITH (General Electric Co.). *General Electric Review*, Vol. 33, Sept. 1930, pages 511–513.

Thyratron tubes have been used as make-and-break device in control equipment to answer the severe requirements of interrupted line welding. The control system and novel features of the applications are discussed. WHB(11c)

Investigations of the Most Favorable Mixture-Ratio in Acetylene-welding of Steels with Low Carbon Contents (Untersuchungen über das günstigste Mischungsverhaltnis bei der Azetylen-Schweissung von Stählen mit geringem Kohlenstoffgehalte). O. MUES. *Forschungsarbeiten auf dem Gebiete der Azetylen-Schweissung*, Jan. 1930, pages 25–52.

Briefly expressed, the extensive research had the following results: (1) The oxy-acetylene welding flame has, for ratios of oxygen to acetylene from 1.0 to 1.4, a neutral core in the flame center where neither carbonizing nor oxidation of the melt takes place. This neutral zone is largest for the ratio 1.0. (2) Tests with ratios from 0.89 to 2.09 showed the best quality of the melt at a ratio of 1.0 to 1.1. (3) The hardness of the seam reduces with increasing ratio. (4) Within the ratio of 0.89 to 2.09, the output of the welding increases with increasing ratio. (5) The least change of the mixture ratio for changes of pressure before the burner occurred in burners for equal pressures, greater changes in injector-burners, and the largest in mixing-nozzle burners. (6) The heating of the burner-head causes, in all burners except the uni-pressure burner, a change in the mixture-ratio. (7) The back-firing velocity of the free upward burning flame increases in the examined ratios with increasing ratio and increasing temperature of the mixture. For details, reference must be made to the paper; there are 27 references and 6 pages of tables illustrating test results. Ha(11c)

General Survey of Welding Processes. F. T. LLEWELLYN (U. S. Steel Corp.). *Preprint, American Society for Testing Materials*, Mar. 1931, 15 pages.

Condensed general description and classification of all welding processes. This is to appear also in the A.S.S.T. Handbook. HWG(11c)

Welding in the Chemical Industry. F. LEVERICK. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 448–451.

This is a discussion of welding as compared with other methods of joining, the different types of welds, the precautions to be observed in the welding of corrosion-proof metals, all from the point of view of the engineer who is responsible for the installation of chemical plant equipment. MPB(11c)

English Practice in Repair Welding. A. ANDREWS. *American Machinist*, Vol. 73, Dec. 25, 1930, page 1002.

Oxy-acetylene is favored for aluminum castings. Electric arc is more rapid for other work. Welding rods should be of about the same composition as the casting to be welded. Preheating is usually required for aluminum castings. Flux should be washed off to prevent future corrosion. RHP(11c)

Welding of Duralumin in Aircraft. EDWIN JOYCE. *Welding*, Vol. I, May 1930, pages 447–453.

Based on research work being done at U. S. Naval Aircraft Factory, Philadelphia, Pa. Discusses experimental data on duralumin, heat treatment of welds, composition of flux recommended, prevention of distortion, importance of properly formed flanges, scleroscope hardness readings, combating corrosion. Includes 2 tables on results of tensile tests of oxy-hydrogen flame, flange welded 0.045 gage and 0.029 gage duralumin and graphs of scleroscope hardness of welded duralumin sheet. ACW(11c)

Welding of Formed and Fabricated Sheet Metal Parts. J. B. GREEN (Fusion Welding Corp.). *Metal Stampings*, Vol. 3, Mar. 1930, pages 267–270.

Welding of thin steel sheets is very largely a matter of precision heat control. Metallic arc process is unsuitable for sheets thinner than No. 14 gage because of wide variation in the heat developed from instant to instant. Carbon arc tends to pull off from the cold steel along the edges of the weld. Thin sheets can be welded satisfactorily by means of a combination of a carbon arc and a suitably fluxed welding wire developed for the purpose. Flux-protected metal steadies arc and insures the path of least resistance for the arc stream to lie between the carbon point and the hottest spot. Cross-section of the wire is so proportioned to the thickness of the sheets that an inch of weld seam can be laid down with an inch of wire. Specially designed generator provides precision heat control. Sheets down to No. 30 gage can be welded by this process. Al, Cu and "18–8" and other alloy steel sheets may be welded by using special fluxes. MS(11c)

Riveting (11d)

Studies of Lautal, with Special Consideration of Riveting Lautal (Untersuchungen an Lautal unter besonderer Berücksichtigung der Lautalnietung). OTTO REPP. *Hauszeitschrift der V. A. W. und Erftwerk für Aluminium*, Dec. 1930, pages 229–279.

The paper gives a complete account of the mechanical-technological investigation of the light metal, "Lautal," which is composed of 94% Al, 4% Cu, 2% Si, has a density of 2.75 and is normally annealed at 500° C., quenched, and again tempered at 120–150° C. Tests were made with rounds or sheets. Static and dynamic tests were made. The rivets are cold pressed into the rivet holes, the energy transmission acts, therefore, contrary to the hot method for steel, not by friction of the sheets against each other, but by pressure in the hole and compression in the rivet. The principles of calculation are derived and coefficients for stresses are given. The test results are shown in numerous tables to which the reader must be referred. Ha(11d)

Riveting of Aluminum and Its Alloys. (Note sulla Chiodatura dell'alluminio e sue leghe). U. MAGNANI & C. PANSERI. *La Metallurgia Italiana*, Vol. 23, Jan. 1931, pages 1–17.

General discussion of riveting heat-treatable Al alloys, with some comment on electrolytic corrosion where these alloys are in contact with others, on protective coatings, and on thermal coefficient of expansion. HWG(11d)

Melting & Refining (12a)

Deoxidation and Mold Conditions on the Tensile Properties of Carbon Steel Castings. J. V. MCCRAE & R. L. DOWDELL. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 159–211; *Rolling Mill Journal*, Vol. 4, Oct. 1930, pages 521, 524, 552.

Paper presented before 12th annual Convention of the Society in Chicago Sept. 1930, with discussion, containing 7 references. The paper discusses the difficulties of meeting in C steel castings a specification of minimum tensile strength 60,000 lb./in.², minimum yield point 45% of tensile strength, minimum elongation in 2 inches 24% and minimum reduction of area 35%, determined on a 0.505 in. tensile specimen. This specification is quite generally met by casting in dry sand molds but reasons of economy make green sand desirable and here difficulties of porosity are encountered. This may be eliminated by the use of Al in the ladle but results in decreased ductility. To determine the extent of these difficulties 100 consecutive heats from one foundry and 32 (not all consecutive) heats from another foundry were studied. The plan involved the varying of ordinary foundry conditions such as green and dry sand molds, design of test castings, heat treatment, casting temperature, character of scrap and various deoxidizers and deoxidation conditions. The melting was in $2^1/_2$ ton Heroult and 2 ton Greaves-Etchell furnaces and the practice was normal for acid electric castings. Composition study showed low C, 0.13–0.18, most easily meet the specification when made under "standard melting" conditions. Thermal analysis showed Ac_3 to be higher in these castings than in wrought steels of the same composition. Higher temperatures of normalizing failed to increase ductility. Of various treatments tried such as quenching and tempering, higher normalizing, and the various draws, a draw of 1300° F. after the usual 1650° F. normalize improved the ductility of poor heats but had no appreciable effect on good heats. Use of higher casting temperatures appears beneficial. Character of the scrap appears to be of little influence though the use of large amounts of heavy scrap is preferable. Addition of small amounts of Ni and Va appear to have no virtue. Of various deoxidizers tried none showed better ductility than Al and some very inferior results. Al alloys have the same effect as an equal amount of Al as such. Inclusions of Al_2O_3 appear to be the cause of low ductility when Al is used. Mold preparations in the form of surface treatments may give desired results but do not appear very promising. In discussion W. C. Hamilton (American Steel Foundries) summarizes the results presented and reports experience with open-hearth steel for castings and use of Al. A. W. Lorenz (Bucyrus-Erie Co.) presents data on the addition of Al to open-hearth steel for castings. MS + WLC(12a)

Making and Working White Gold. (Herstellung und Bearbeitung von Weissgoldlegierungen.) EDMUND RICHARD THEWS. *Deutsche Goldschmeide Zeitung*, Vol. 34, Mar. 14, 1931, pages 112–113.

The Au-Pd alloys are easier to work and more resistant to tarnishing than the Au-Ni-Zn alloys, but the latter are usually used because they are much cheaper. The quality of the Au-Ni-Zn alloys is dependent on the method of melting. They should be prepared by melting the Ni under a borax cover, gradually adding the Au, cooling to 1050° or 1100° C., deoxidizing with Mg, stirring the Zn in, and finally adding Mg before casting. Remelted alloys may differ from alloys made from new metals. The Au-Ni-Zn alloys are harder than the yellow or red-gold alloys, and much more difficult to work. They are particularly susceptible to rapid changes in temperature, and while hot should not be dipped into the pickling solution. They should be annealed at not over a dark cherry red. At annealing or heating for soldering they should be protected from the O_2 of the air by a covering such as borax. They can be pickled in a 10% H_2SO_4 solution. Directions are also given for electrolytic cleaning. For plating a Au-Cd solution is recommended. JLG(12a)

Iron and Steel Foundry Practice. Part 7. BEN SHAW. *Metallurgia*, Vol. 3, Jan. 1931, pages 104–108.

Describes the usual arc and induction furnaces used in steel melting. JLG(12a)

Some Metallurgical Points on Acid Open-Hearth and Electric Steel for Castings. F. A. MELMOTH. *American Foundrymen's Association, Preprint* No. 31–5, 1931, 25 pages.

Indications are that, although chemically identical, open-hearth and electric steels are not necessarily identical in constitution. Non-metallic inclusions in electric steel are considered as cause for differences in the 2 types of steel. Their presence may be of ultra-microscopic size. CHL(12a)

Reverberatory Type Furnaces Used in Recovery of Waste from Tin-Base Babbitting. P. J. POTTER. *Fuels & Furnaces*, Vol. 8, Mar. 1930, pages 393–394.

The Carbon-oxygen Equilibrium in Liquid Iron. H. C. VACHER & E. H. HAMILTON (U. S. Bureau of Standards). *Technical Publication* No. 409, *American Institute Mining & Metallurgical Engineers*, 1931, 17 pages.

Alloys containing various concentrations of C and O were prepared by controlling the CO_2/CO ratio of the gases in contact with the melt. The value of the product C·O in weight % at 1620° C. and 1 atmosphere pressure was found to be 0.0025. This value did not vary as the C varied from 0.01 to 0.94% and the O from 0.003 to 0.19%. In the higher C alloys the O was determined by deoxidation with Al and determining the Al_2O_3. In the low C alloys the O was determined by vacuum fusion. 7 references. JLG(12a)

Investigations on the Chemical Reactions in Making Acid Steels and in Deoxodizing with Manganese and Silicon (Untersuchungen über die chemischen Vorgänge bei den sauren Stahlerzeugungsverfahren und bei der Desoxydation des Stahles mit Mangan und Silizium). H. SCHENCK. *Archiv für Eisenhüttenwesen*, Vol. 4, Jan. 1931, pages 319–322.

The metallurgical similarity of the reactions of Mn and Si in making acid steel and in the final deoxidation process can be utilized to refer the 2 processes to each other. In order to establish the equilibria, it is necessary to know the constants of equilibrium of the reactions $FeO + Mn \leftrightarrows MnO + Fe$ and $2\,FeO + Si \quad SiO_2 + 2\,Fe$ as well as the constants of dissociation of the silicates of Fe and Mn. After presenting the present known thermal data, the constants of the above reactions were calculated, compared with other data and found suitable for application. The constants of dissociation of the Fe and Mn silicates were determined and the relations of equilibrium between metal bath, slag and the products of deoxidation diagrammatically represented. The deoxidation of Mn and Si steels is discussed. GN(12a)

Production of Gray Iron from Steel Scrap in the Electric Furnace. T. F. BAILEY. *Fuels & Furnace*, Vol. 8, May 1930, pages 667–669.

Deoxidation of Steel with Silicon. C. H. HERTY, JR., G. R. FITTERER & C. F. CHRISTOPHER. *Bureau of Mines Technical Paper* 492, 1931, 42 pages.

The liquidus of the system $FeO-SiO_2$ has been studied over the range 45–100% FeO. The melting points of synthetic ferrous silicates were determined with the micropyrometer. Fayalite ($2FeO.SiO_2$) melted at 1335°. Two eutectics, at 65 and 78% FeO, were found; their melting points were 1260° and 1240°, respectively. The deoxidation constant for the reaction $2FeO + Si \rightleftarrows SiO_2 + 2Fe$ was determined to be $K_D = (Si)\ (FeO)^2 = 1.65 \times 10^{-4}$ when all concentrations are expressed as weight percent. Fluxing of silica by dissolved FeO was shown to be an important factor in the deoxidation of low-carbon steel. Steels high in silica are red-short in forging, while steels containing ferrous silicates high in FeO forged without cracking. The use of silicon as a deoxidizer in steel-making processes always results in the formation of silica or silicates, depending on the amount of silicon used and the concurrent use of other deoxidizers. If silicon is used alone the silica formed is extremely hard to eliminate. The oxidation of the metal in the basic open-hearth process increases as the carbon content decreases. The time required to eliminate silicates, resulting from deoxidation with silicon, from the steel bath was proportional to the depth of the bath and inversely to the size of the particles formed on deoxidation. Agitation of the bath assisted in cleaning it. High residual manganese had only a slight cleaning effect. Segregation of silicates in ingots from 20 lbs. to 3 tons in weight was studied. In top-poured steels the maximum segregation was in the center of the ingot about 15% from the bottom. An annular zone of high-silicate segregation was found in the upper portion of these ingots and is due to crystallization phenomena. In bottom-poured ingots segregation is more irregular and is complicated by erosion of runner brick. AHE(12a)

The Production of High-Manganese Slag in the Electric Furnace. T. L. JOSEPH, C. E. WOOD & E. P. BARRETT. *Bureau of Mines Report of Investigations* 3080, Feb. 1931, 9 pages.

Electric furnace tests made with 150-lb. charges of spiegel, containing about 15% Mn and 0.5% P indicate that 2 types of high-Mn slag may be produced from metal of this type. When silica was used as a thinning agent the slag had an average composition of MnO 68.1, FeO 5.2, SiO_2 14.3, P 0.11, and Al_2O_3 8.2%. With the exception of frothy slags, alumina worked as well as silica as a thinning agent, resulting in slag of the following average composition; MnO 69.6, FeO 6.1, SiO_2 8.7, P 0.16 and Al_2O_3 13.0%. The silica and alumina may be varied over a wide range provided their sum equals about 22% of the slag. A continuous cycle gave better results than a batch operation. From 85 to 90% of the Mn could be recovered in the slag, 3 to 6% in the metal and 6 to 8% lost. More strongly reducing conditions can be established in the electric furnace than in the open-hearth thus permitting more positive control of phosphorus and iron in the slag and reducing the treatment to about one-half. Steel Ingot. HERBERT H. ASHDOWN (Consulting Metallurgist). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 129–158.

Paper presented before the 12th annual Convention of the Society in Chicago, Sept. 1930, with discussion. The paper discusses difficulties met in production of large ingots for forgings and gives details of small and large scale investigation of the causes of failures. Photographs of sulphur prints and macroetched sections show the occurrence of segregation in ingots discussed. The advantages of rotating ingots during casting, and the use of water cooled ingot molds to secure rapid solidification, arresting segregation, shortening pipe and producing a larger portion of sound material in each ingot are shown. The occurrence of ingot corner segregation and corner cracking is discussed. Virtues of big end up and big end down types of molds are discussed. The advantages of cylindrical ingots in eliminating corner segregation are covered. In discussion P. A. E. Armstrong proposes use of cylindrical ingot molds of Cu with a cast iron bottom to be mechanically dropped to allow the ingot to settle into contact with the mold as it contracts. Cu lends itself more readily to water cooling and has a much higher conductivity giving quicker and more effective relief of heat. WLC(12b)

The Casting of German Silver in Water-Cooled Chill Moulds. OTTO JUNKER (Lammersdorf, Kreis-Monschau). *Metal Industry*, London, Vol. 37, Aug. 1, 1930, pages 103–104.

Translation adapted from an article in *Metallwirtschaft*. Results given prove the economy of casting German silver sheet slabs in water cooled chill molds. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 430. VSP(12b)

The Centrifugal Casting of Metals. O. JUNKER. *Metal Industry*, London, Vol. 36, April 25, 1930, pages 453–454.

Adapted from communication by the author to *Metallwirtschaft*, Oct. 1929, page 1018. Describes the type of water cooled centrifugal mold. Attention is drawn to the method of admitting water in opposition to centrifugal force which is to insure complete contact of water with the mold. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 430. VSP(12b)

Some Notes on Teeming Speeds of Ingots. A. JACKSON. *Iron & Steel Industry & British Foundryman*, Vol. 4, Feb. 1931, pages 167–170.

A study of 6 ton ingots show that too rapid teeming rate tends to cause cracking of ingots. CHL(12b)

Crystallization and Segregation in Small 1.10 Percent Carbon Steel Ingots. AXEL HULTGREN. *Rolling Mill Journal*, Vol. 4, Mar. 1930, pages 107–108.

Abstract of a paper read before the *Iron & Steel Institute*. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 388. MS(12b)

Rolling (12c)

Malleability of Rolled Soft Steel, and a New Method for Its Improvement. JOSEPH VIETORISZ. *Carnegie Scholarship Memoirs, Iron & Steel Institute*, Vol. 19, 1930, pages 167–213.

The author has studied the effect of various rolling temperatures from 200–1300° C. on the properties of soft steel. He finds a critical range between 700° and 850° C. where the mechanical properties are very poor. At 900° C. the elongation reaches its highest value and lowest at 300°. "Hot" rolling, above the critical range, gives a comparatively low yield point but 850–1000° C. gives the highest values. If lower elongation is satisfactory much higher yield point may be obtained by "cold" rolling at 200–400° C. A micro-structural study was made with grain counts tabulated and 37 micrographs. The steel studied analyzed C 0.05%, Mn 0.29%, P 0.02%, S 0.035% and Si a trace. 6 references. WLC(12c)

Calculation of the Spread of a Rail Pass (Ueber die Ermittlung der Breitung bei einem dem Schienenstaucherähnlichen Profilstich). H. PUPPE. *Stahl und Eisen*, Vol. 50, Oct. 30, 1930, page 1529.

The author describes a method for calculating the spread of the material of a rail, so as to allow sufficiently for properly finishing the flanges of long rails. GN(12c)

Useful Work and Lost Work in Rolling (Nutzarbeit und Verlustarbeit beim Walzen). E. SIEBEL & A. POMP. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, No. 11, Report 153, pages 149–159.

The losses in cold and hot rolling were studied. The high losses in cold rolling are attributed to friction in the bearings. Roller bearings with pressure lubrication gave the best results. The ratio of the losses to the total work done is smaller in hot rolling, due, primarily, to the fact that the angle of grip is larger in hot rolling than in cold rolling, so that, for equal amounts of work, the roll pressure is less and, therefore, smaller frictional losses occur. A mathematical consideration of the forces generated by rolling is given. GN(12c)

On the Cross-rolling Method in Rolling Large Seamless Tubes (Ueber Querwalzverfahren zur Herstellung grosser nahtloser Rohre). K. GRUBER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 162, pages 285–297; *Stahl und Eisen*, Vol. 50, Dec. 18, 1930, page 1788.

The article deals with pass and mandrel design in rolling seamless tubes. The main conditions which must be fulfilled are as follows. (1) Rolls and rolled material shall be rotation bodies which are always in contact. (2) A twisting of the material should be avoided during the rolling process. (3) The rolling speed in the direction of the axis of the material should be constant. The second condition cannot be fulfilled accurately. Practical results check the above theoretical considerations. Data on the power consumption are included in the paper. GN(12c)

The Rolling of Alloys of Copper and Phosphorus Containing up to 5 Per Cent of Phosphorus. OWEN W. ELLIS (Ontario Research Foundation). *Institute of Metals, Advance Copy* No. 551, 1931, 6 pages; *Metal Industry*, London, Vol. 38, Mar. 20, 1931, pages 315–316.

Contrary to recent reports Cu containing as much as 5% P can be rolled. Sheets for brazing have been rolled to 0.015 in. The Cu-P alloys were rolled at a temperature of 450° C. or above to between 0.02 and 0.04 in., and then rolled cold. A strip of the 5% P alloy, 0.018 in. thick had a tensile strength of 88,000 lbs./in.^{2} and practically no elongation. PRK + JLG(12c)

Forging (12d)

Forging Practice in U. S. Naval Gun Factory. W. L. BLANKENSHIP. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 73–99.

Paper presented before the 12th annual Convention of the Society, Chicago, Sept. 1930, with discussion. The limitations of space and weight available and the necessity for the utmost reliability in Naval Ordnance make the manufacture of naval forgings a very exacting work. The author gives various compositions used and mentions applications. The question of quality in the metal for forgings is discussed with details for the production of certain forgings and tests used for control of quality. The forging of aluminum bronze for naval work is discussed and physical properties given. The paper is concluded with a discussion of projectile forgings and special equipment developed for their efficient quantity production. H. H. Ashdown, in discussion, comments on the necessity for high-grade ingots and the control of forging temperatures. WLC(12d)

Extruding (12f)

Modern Extrusion Presses for Tubes, Rods, and Sections. *Metal Industry*, London, Vol. 38, Mar. 6, 1931, pages 271–272.

Description of new extrusion presses made by Krupp Grusonwerk of Magdeburg. Modern presses are arranged to operate according to 2 working processes: (1) Direct—best for extruding wide strip and thin wire, (2) Inverted—which requires lower extrusion pressure and lower amount of discard of billet. Modern presses have head plate and cylinder made in a single steel casting, doing away with tie columns and nuts. PRK(12f)

The Influence of Pressure and Temperature on the Extrusion of Metals. C. E. PEARSON & J. A. SMYTHE (Armstrong College). *Institute of Metals, Advance Copy* No. 558, 1931, 25 pages; *Metal Industry*, London, Vol. 38, Mar. 20, 1931, pages 311–314; Mar. 27, 1931, pages 339–342; Apr. 3, 1931, pages 361–362; Apr. 17, 1931, page 410.

In the direct extrusion process a force is applied at one end of a billet to force the metal through a die at the opposite end, while in the inverted process the force is applied through the die. For a given temperature and rate of extrusion the inverted process requires only about one-half the power required for the other process. Extrusion was studied in a small press by extruding Pb, Bi, Cd and Sn. Determination of the flow in Bi showed that in the direct process the entire billet was worked, while in the other process only the portions adjacent to the die were worked. With a lubricant between the billet and wall the power required in the direct process is greatly decreased. The dependence of rate of extrusion on the pressure and temperature is determined for the several metals. 8 references. PRK + JLG(12f)

Machining (12g)

Factors Affecting Machinability of Malleable Cast Iron. H. A. SCHWARTZ. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, July 1930, pages 210–258.

Machinability of malleable cast iron was determined by measuring the torque and thrust of a drill advancing at constant speed, and the feed and torque of a drill advancing under constant pressure. Machinability is largely determined by the carbon content of the iron. CHL(12g)

Design and Construction of Hot Saws for Cutting Heavy Sections. A. B. PEARSON (Carnegie Steel Co.). *Iron Age*, Vol. 126, Oct. 30, 1930, pages 1226–1228, 1277–1278; *Rolling Mill Journal*, Vol. 4, Dec. 1930, pages 683–687.

Includes discussion. Abstract of paper read before the Iron & Steel Division of the American Society of Mechanical Engineers at Chicago, Sept. 1930. Describes saws for cutting hot and cold metals and gives results of tests on a variety of saws. MS + VSP(12g)

Torque, Thrust and Power for Drilling. O. W. Boston & C. J. Oxford. *S. A. E. Journal*, Vol. 28, Mar. 1931, pages 378–383.

Tests on drilling various grades of steel and cast iron were conducted in a specially equipped drilling press at the University of Michigan and reported in detail in a previous paper. The present paper is an extension of the results of these tests in formulas, tables and charts for determining the thrust, torque and horsepower that will be required in practice for drilling with drills of 1½ in. or smaller diameter in the various materials that were tested, which were representative of those commonly used in industry. (12g)

Hard Metal Carbides and Cemented Tungsten Carbide. Samuel L. Hoyt (General Electric Co.). *Transactions, American Institute of Mining & Metallurgical Engineers, Institute of Metals Division*, 1930, pages 9–58.

Lecture at New York meeting, Feb. 1930. The literature on hard metal carbides is reviewed. Commercial cemented tungsten carbide is made by mixing WC with Co powder and sintering. The WC is prepared by heating W powder in H together with C. The Co powder is prepared by H reduction. The 2 powders are mixed in a ball mill. Micrographs show the structures of the products. The Vicker's Brinell hardness is as high as 1450, and the density is as high as 15. Graphs showing the high cutting efficiency of the cemented carbide are presented. Contains 45 references. JLG(12g)

Drawing & Stamping (12h)

The World's Wire Drawing Practice. K. B. Lewis. *Wire & Wire Products*, Vol. 5, July 1930, pages 265–266, 285–288; Aug. 1930, pages 306–307, 327–330.

The methods of wire drawing in Europe, Canada and Mexico are outlined. GN(12h)

Recent Development in Wire Drawing and Forming Machinery. C. S. Arms. *Wire & Wire Products*, Vol. 5, July 1930, pages 267, 288–289.

General discussion. GN(12h)

Die Lubricants and Lubrication. R. T. Kline. *Wire & Wire Products*, Vol. 5, Dec. 1930, pages 466–467.

The proper lubricant for wire drawing is determined by wire, die and drawing speeds. GN(12h)

Studies of the Wire-Drawing Process. I. The Application of Photo-Elastic Methods to the Problem of Wire-Drawing Stresses. F. C. Thompson & J. Barton. *Carnegie Scholarship Memoirs, Iron & Steel Institute*, Vol. 19, 1930, pages 39–78.

Paper received Sept. 6, 1929, contains 6 references. Photo-elastic study by the method evolved by Coker maps of the stresses in isotropic celluloid strips drawn between dies was made. Certain differences were noted due to the shape of dies and the experimental technique is not strictly analogous to wire drawing. The results reported are of a preliminary nature and form the ground work for further study of wire drawing. WLC(12h)

Forming Properties of Thin Sheets of Some Nonferrous Metals. W. A. Straw, M. D. Helfrick & C. R. Fischrupp (Western Electric Co.). *Technical Publication* No. 406, *American Institute Mining & Metallurgical Engineers*, 1931, 14 pages.

The smallest radii on which various commercial brasses, bronzes and nickel-silver sheets can be bent in a punch press were determined. Sheets of several hardnesses were used. Strips ¾ in. wide were formed with a 90° V die and 90° wedge shaped punches; the punches being made with the edges ground to various radii. Tables are given indicating the radii over which the various alloys, in various thicknesses and tempers can be bent without cracking. As examples a ½ hard 65–35 brass can be formed with a sharp punch at gages from 20 to 11, while the hard sheet can be formed in this manner only when thinner than 15 gage. With this alloy and temper a 15 gage sheet requires at least a 0.0156 in. radius, and an 11 gage sheet requires at least a 0.0937 in. radius. JLG(12h)

Metallurgy of the Modern Die Set. John H. Hruska. *Iron Age*, Vol. 127, Feb. 26, 1931, pages 702–705.

Castings for die sets are made almost exclusively from semi-steel or a special grade of gray cast Fe. Heat treatment of die set castings. Increased temperature decreases hardness, prolonged heating enlarges graphite flakes of matrix and decreases transverse strength. Leader pins and bushings are made of pearlitic Mn steels. Box carburizing is desirable in case of long leader pins and bushings. Rotary furnace has certain outstanding features so far as quick production and low cost is concerned. Drawing may be done in rotary furnaces, salt pots or oil tanks with accurate temperature regulation. Results of analyses are tabulated. VSP(12h)

Causes of Internal Stress and Season Cracking in Drawn Brass Tubes. D. K. Crampton (Chase Brass & Copper Co.). *Metal Stampings*, Vol. 3, May 1930, pages 453–456, 462.

Hard Metal Substitutes for Diamonds. A. Ackermann. *Wire & Wire Products*, Vol. 5, Nov. 1930, pages 430, 437, 438.

Discussion of composition and advantages of various German hard metals for wire drawing dies. Description of the preparation of dies and special lubricants, precautions in drawing copper wire. GN(12h)

Pickling (12i)

Metalware Pickling Data. Wallace G. Imhoff. *American Metal Market*, Vol. 38, Mar. 20, 1931, pages 5, 10; Mar. 21, 1931, page 5; Mar. 24, 1931, pages 5, 10.

Data are included in 28 tables and show the results obtained in a number of plants on the pickling of hot galvanizing of 12 qt. light water pails. The weights of zinc deposited differed by 19⅛ lbs. per gross deposited as coating. WHB(12i)

Cold Working (12j)

Principles of Cold Up-setting and the Limitations. S. Hillman. *Metal Progress*, Vol. 1, Oct. 1930, pages 58–59.

Brief discussion. WHK(12j)

The Cold Rolling of Strip Steel. Stephen Badlam. *Yearbook American Iron & Steel Institute*, 1930, pages 352–444.

Includes discussion. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 44. (12j)

Surface Compression. (Das Drücken der Oberfläche.) Hilmar Döring. *Metallwirtschaft*, Vol. 9, Aug. 22, 1930, pages 702–706.

Contains 5 references. Bronze, Cu, Al alloys, cast iron, carbon and alloy steels were cold worked on the surface in a specially constructed press. The endurance limit was raised 8–11% by the cold working in every case except cast iron, in which no change took place. It was not determined whether a greater increase is possible. In some instances the cold working caused small internal cracks at inclusions. Surface irregularities can be overcome by cold working. CEM(12j)

Cleaning (12k)

Effect of Impurities in Cleaning and Finishing Materials. R. F. Cohn. *Metal Cleaning & Finishing*, Vol. 2, Feb. 1930, pages 103–106.

Impurities may exert beneficial effects as well as detrimental. Gives some specific examples. Ordinary impurities in H_2SO_4 for pickling have no significance. However, As renders the acid useless for pickling. Cheaper soaps, with fillers and a small amount of free alkali, are better cleaners than "pure" soaps. Electroplated finishes are more satisfactory if proper attention is paid to the purity of chemicals used and the purity of the deposit. Extremely pure Zn is hardly attacked by 10% HCl, which dissolves commercial high grade Zn almost at once, and dissolves 53% of the weight of C. P. Zn in the same time. On the other hand in HNO_3, the extremely pure Zn dissolves completely, the C. P. Zn loses half its weight, and the commercial high grade metal loses only one-third its weight. MS(12k)

Polishing & Grinding (12l)

Fifty-seven Foot Grinding Machine Believed to Be Largest of Its Kind. *Grits & Grinds* (Norton Company), Vol. 21, Dec. 1930, pages 8–10.

Description of machine that will grind cylindrical work up to 36-in. diam. and 288-in. length weighing up to 40,000 lb., easily within 0.0005 in. for concentricity and straightness. In a trial it removed stock from a cast iron column at rate of 6 cu. in. per minute. MFB(12l)

Grinding problems in the production of aeronautical engines; machines and special fixtures, etc. MFB(12l)

DEFECTS (13)

Deep Etching of Brass. W. F. Graham & L. A. Meisse. *Transactions & Bulletin American Foundrymen's Association*, Feb. 1931, pages 810–825.

Deep etching of brass with a solution of nitric acid (1.42 specific gravity) and 10% by volume of hydrochloric acid (1.18 specific gravity) clearly brings out areas of discontinuity of the structure caused by sonims, crystal boundaries or dendrites. CHL(13)

Non-Metallic Inclusions in Metals. G. F. Comstock. *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 348–354, 8 figures.

Brief general discussion. Wohrman's modification of the methods outlined by Campbell and Comstock for identification of inclusions is reproduced. A few micrographs of typical inclusions are given. HWG(13)

A New Type of Inclusion in Cast Iron and its Relation to Manganese and Silicon Content. F. J. Cook. *American Foundrymen's Association, Preprint* No. 31–14, 1931, 12 pages.

Glassy inclusions, heretofore not described, appear in cast iron when the Mn is within 0.4% of the Si content. They do not affect the wearing qualities of the iron. Believed though not definitely proven to be manganese silicate inclusions. CHL(13)

Origin and Effect of Inclusions in Steel. B. M. Larsen. *Metals & Alloys*, Vol. 1, Sept. 1930, pages 703–713; Oct. 1930, pages 763–769; Nov. 1930, pages 819–825.

A review. ESC(13)

Inclusions and Their Effect on Impact Strength of Steel. A. B. Kinzel & Walter Crafts (Union Carbide and Carbon Research Labs.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 402, 1931, 33 pages.

The sizes and quantities of inclusions in several Ni and Cr-V steels were determined from micrographs of carefully polished sections. Inclusions having a diameter above 0.005 mm. were counted. The number of inclusions per mm.^{2} varied from 44 to 96. Tensile impact tests were made on the same steels normalized. The samples were cut both from the center and from an intermediate zone. The dynamic strengths of the steels decreased as the inclusions increased, and curves are given to show the exact relationship between quantity of visible inclusions and dynamic properties. The magnitude of the effect of the inclusions increases as the hardness of the steels increases. "Body" is influenced by inclusions smaller than 0.005 mm. Inclusions were obtained as residues and analyzed. The quantity of inclusions was directly proportional to the oxide-manganese sulphide ratio of the residues. JLG(13)

Non-Metallic Inclusions in Iron and Steel. (Nichtmetallische Einschlüsse in Eisen und Stahl). A. Bajkoff (Institut für Metallkunde, Russia). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 355–362.

General discussion with micrographs. HWG(13)

The Occurrence of Fractures in Hard Soldering Steel (Das Auftreten von Brüchen beim Hartlöten von Stahl). *Stahl und Eisen*, Vol. 50, Oct. 2, 1930, pages 1403–1405.

Correspondence between W. Albert and W. Riede on Riede's paper on the above subject in *Stahl und Eisen*, Vol. 49, 1929, pages 1161–1162. GN(13)

Failures of Cast-iron Kettles in Lead Refining. Carl E. Swartz (American Smelting and Refining Co.). *Technical Publication* No. 389, *American Institute Mining & Metallurgical Engineers*, 1931, 13 pages.

Data were obtained on 5 kettles whose life ranged from 11 to 1180 heats. The kettles with a long life had a gray fracture, while less satisfactory ones had a black fracture. Rapid failure is frequently due to overheating or to non-uniform heating. In some cases temper carbon had been formed near the fracture. In most cases the pearlite had been divorced in the heated portions of the kettle. Fire cracks that originated in graphite flakes were observed. JLG(13)

Diagnosis of an Interesting Mechanical Failure. Gordon Sproule. *Canadian Foundryman*, Vol. 22, Feb. 1931, page 10.

The author, after discussing the fundamentals of crystalline structure, deals with the failure of the tapered pinion seat of a motor armature shaft, the keyway of which, after having been worn in service, was filled by adding metal by welding. The effect of applying the coatings of metal was such as to cause the ultimate failure of the shaft. A criticism of the methods adopted is given. OWE(13)

Hair Line Cracks. T. M. Service. *Royal Technical College Metallurgical Club Journal*, Glasgow, No. 7, 1929–1930, pages 9–15, 17 references.

Chiefly a discussion of the work and opinions of others. In the author's work on 49 forgings of approximately 0.27% C, 3.60% Ni, 0.70% Cr, 0.50% Mn, those forgings allowed to become cold, and then reheated above Ac_3 showed hair cracks; those heated below Ac_1 did not. Service believes that the cracks are due to differential cooling stresses which do not appear as cracks till the stress is released, as by cutting off a disc. The cracks can be prevented by suitable control in annealing. HWG(13)

ECONOMIC (16)

Engineering Markets of the World. VI. A. J. LIVERSEDGE. *Engineering*, Vol. 130, Nov. 14, 1930, pages 609–610.

Discusses the trade situation of Canada. In 1929–30, Canada imported only 6.8% of its iron and steel and their products from the United Kingdom, while 89% was imported from the U. S. Curves are given showing Canada's engineering imports from 1913 to 1930 incl. from the United Kingdom and elsewhere. For the former, all curves except one end on lower levels than where they began. For cast, forged and rolling mill products, the figures for 1930 are practically the same as for 1913. Preference given to goods from the United Kingdom does not counterbalance the geographical advantage enjoyed by America. Gives table summarizing engineering imports into British Dominions overseas. Briefly discusses trade situation of the United Kingdom and its lesser Dominions, Crown Colonies, and Protectorates. LFM(16)

Secondary Metals in 1929. J. P. DUNLOP. *Mineral Resources of the United States*, 1929, Part 1, Feb. 24, 1931, *United States Bureau of Mines*, pages 179–201.

The quantity of secondary metals recovered in 1929 (as reported) increased 7% over 1928, and amounted to over 1,000,000 tons. There were small decreases in the output of Sn, Ni, Zn and Sb, small gains for Pb and Al and large gains in the output of Cu. Pt recovery was 42,759 oz. (28% of imports), and 13,072 oz. less than 1928. Au and Ag recovery amounted to over $29,000,000. Detailed figures are given. 23 footnotes and textual references. AHE(16)

Northern British Columbia and Yukon in 1930. W. E. COCKFIELD. *Canadian Mining Journal*, Vol. 52, Feb. 6, 1931, pages 138–143.

Promising placer developments in Atkin and Big Salmon districts are noted. Mayo silver reserves were reduced due to the slump in prices. WHB(16)

The Marketing of Nickel. J. W. FURNESS. *Trade Information Bulletin* No. 685, 1930, *United States Department of Commerce, Bureau of Foreign and Domestic Commerce*, 31 pages.

The following subjects are discussed: mode of occurrence, minerals, properties, metallurgy, uses (Ni-Ag, Ni-Fe alloys, Cu-Ni alloys, bronzes, structural Ni-steel, Ni-steel castings, corrosion-resistant steels, Ni cast iron, malleable Ni, coinage, plating, catalyzers, battery plates, heat-resisting electrical alloys, salts, etc.), world production and imports, present day sources, potential resources, and marketing. Over 100 references are given. AHE(16)

Arsenic in 1929. V. C. HEIKES. *Mineral Resources of the United States*, 1929, Part 1, Aug. 29, 1930, *United States Bureau of Mines*, pages 1–4.

Production of arsenious oxide in the United States in 1929 amounted to 16,605 short tons of which 11,071 tons was refined. All the output was a by-product from smelting Cu and Pb ores. AHE(16)

Lead in 1929. ELMER W. PEHRSON. *Mineral Resources of the United States*, 1929, Part 1, Mar. 7, 1931, *United States Bureau of Mines*, pages 231–264.

In 1929, 672,498 short tons of primary Pb was produced from domestic ores (a 7% increase over 1928), and 102,135 tons from foreign ores and base bullion (a 34% decrease from 1928), a net decrease of about 1%. Secondary Pb recovery was 311,000 tons (308,600 in 1928), 46% of the primary Pb from domestic ores. Total Pb consumption passed all previous records, amounting to 945,200 tons, 2% increase over 1928 and 12% over 1927. Storage batteries took 22.2%, cable coverings 21.8%, white lead 12.5% and building 10.2%. Consumption in batteries and white lead decreased 5 and 4% respectively, while use for cable coverings increased 14%. Domestic mine production increased 3%, being shared generally by all districts. General imports in base bullion decreased 35%; in ore and matte they increased 21%. Exports declined. World smelter production amounted to 1,971,000 tons, an increase of 6% over 1928. Production from all but 2 of the 13 countries producing 1% or more of world's Pb was increased over 1928. AHE(16)

Report 45 of the Committee of Plant Economy of the Verein deutscher Eisenhüttenleute. General discussion of the economy which can be achieved in large steel plants by detailed recording of the production. A "standard" example is given for a rolling mill. GN(16)

The Nickel Industry. *Canadian Mining Journal*, Vol. 52, Jan. 30, 1931, pages 22–24.

An official review of the enlarged mine and smelter facilities and of the expanding markets for nickel and its alloys. WHB(16)

Progress in the Iron and Steel Industry in 1929. Report of the Executive Committee of the Iron and Steel Division. *Transactions American Society Mechanical Engineers*, Vol. 52, Jan.–Apr. 1930, pages 1–3.

This gives the progress made by the iron and steel industry in 1929. Some of the subjects discussed include Fe ore, coal, coke, blast furnaces, rolling mills, pipe, wrought Fe, alloy steels, nitriding, centrifugal casting and foreign patents. (16)

The Empire's Zinc Resources II. *Canadian Mining Journal*, Vol. 52, Feb. 20, 1931, pages 201–204.

Australia is the largest producer, while the Canadian output is increasing rapidly. Rhodesia has important resources. The mining areas are briefly discussed. WHB(16)

Lead. G. W. THOMPSON (National Lead Co.). *American Metal Market*, Vol. 38, Feb. 20, 1931, pages 3, 5, 10.

The great increase in consumption of Pb has been in the electrical industry, chiefly for cable coverings. The problem in the future of the Pb and Cu industries will depend largely upon the demand by this industry. Properties of lead and its alloys with Sb and Sn are touched upon. WHB(16)

Platinum. PAUL M. TYLER & R. M. SANTMYERS. *Bureau of Mines Information Circular* 6389, Feb. 1931, 69 pages.

The following subjects are discussed for platinum: properties, uses, alloys, substitutes, history, ores and minerals, occurrence (United States and foreign, by states and countries), assaying, mining, concentrating, refining, production, marketing and prices. Osmiridium is briefly discussed. AHE(16)

Is Electric Heat Economical? WIRT S. SCOTT (Westinghouse Elec. & Mfg. Co.). *Electric World*, Vol. 96, Aug. 2, 1930, page 213.

The economies of electric heat are outlined. Complete factory costs are tabulated for 5 heat-treating plants. The costs are compared with fuel-fired equipments of similar capacity. WHB(16)

PLANTS & LABORATORIES (17)

The British Empire's Largest Copper Refinery. C. H. ALDRICH & J. K. BRYAN (International Nickel Co.). *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1930, pages 489–492.

A general description of the new copper refinery of the Ontario Refining Co., Ltd., at Copper Cliff. The initial capacity is 120,000 tons per annum, and blister copper from the Port Colborne refinery of the International Nickel Co. and from other Canadian plants are refined. WHB(17)

A Modern Electric Steel Plant (Ein neuzeitliches Elektro-Stahlwerk). K. KERPELY. *Giesserei-Zeitung*, Vol. 27, Feb. 15, 1930, pages 101–102.

Description of a new plant in Campia Turzii, Roumania, for the production of Fe and steel wire and wire products of all kinds. Reasons are given for the installation of an electric furnace which is 3-phase arc type with a capacity of 1 to 1.5 tons and is equipped with 500 kva. 3-phase oil transformer with automatic hydraulic electrode regulation of the system. (17)

Cooperative Research. O. W. ELLIS. *Metal Progress*, Vol. 1, Oct. 1930, pages 85–87.

A descriptive account of the metallurgical laboratories of the Ontario Research Foundation. WHK(17)

Employs Semi-Continuous Methods for Rolling Auto Sheets. JOHN D. KNOX. *Iron Trade Review*, Vol. 86, May 1, 1930, pages 119–122.

Description of the plant and practice of the Newton Steel Co., Monroe, Mich. Roughing and finishing mills are installed in separate trains, thus eliminating back-tracking. Each finishing mill has an individual pack furnace, the packs being heated to 1350–1375° F. Some of the sheets are normalized in oil-fired furnaces. Annealing is done in producer-gas fired, box-type furnaces. MS(17)

Heat-Treats Taps and Dies Electrically. F. A. WESTBROOK. *Industrial Record*, Dec. 1930, pages 22, 54, 56.

Description of equipment at plant of Winter Brothers, Wrentham, Mass., manufacturers of taps and dies. Electrically heated furnaces include a drawing oven, a box-type furnace for general use at 1600° to 1800°F., 5 pot furnaces of different sizes, and a high-temperature box-type furnace for hardening high-speed steel. Automatic temperature control is featured. Special interest attaches to furnace for hardening high-speed steel: heat treating by diamond block method—parts to be hardened placed in slotted holes in blocks of carbonaceous compound which are kept in the furnace all the time. Very efficient from production standpoint, one workman frequently obtaining production of 6000 taps/day. Blocks last for 3 days. Spoilage is zero. MFB(17)

Reversing Mill at Tata Iron & Steel Co. J. M. WILLIAMS (Westinghouse Electric & Mfg. Co.). *Blast Furnace & Steel Plant*, Vol. 18, July 1930, pages 1123–1125.

Illustrated description of the electrical equipment for driving the 35-in. reversing mill at Jamshedpur, India. MS(17)

The Merchant Mill of the Peine Works after Reconstruction. (Das Feineisenwalzwerk des Peiner Walzwerkes nach dem Umbau.) ERICH WOLFF. *Stahl und Eisen*, Vol. 51, Jan. 1, 1931, pages 8–10.

The reconstruction of the mill was undertaken in order to increase its capacity. The mill now has 3 high roughing stands, 2 intermediate stands and 7 finishing stands. The cooling bed was completely changed so that it can be simultaneously served from 2 lines. GN(17)

British and Continental Open-Hearth Steel Works—A Comparison. H. C. WOOD. *Iron Age*, Vol. 126, Nov. 6, 1930, pages 1299–1302; *Engineer*, Vol. 150, Oct. 3, 1930, pages 360–362.

Paper read at Prague meeting of the Iron and Steel Institute. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 14. VSP+LFM(17)

New Mills of the Gulf States Steel Co. WARREN WORTHINGTON. *Blast Furnace & Steel Plant*, Vol. 18, Jan. 1930, pages 93.

Describes new blooming-mill and plate-mill. MS(17)

To Study Special Steels in New Research Laboratory. GEORGE J. COMSTOCK. *Iron Age*, Vol. 126, Sept. 11, 1930, pages 686–687.

Describes an addition to the research laboratory of the Firth-Sterling Steel Co., McKeesport, Pa. VSP(17)

A Twelve Hundred Acre Airplane Project. C. A. VAN DUSEN AND OTHERS (Glenn L. Martin Co.). *American Machinist*, Vol. 73, Nov. 27, 1930, pages 837–865.

Description of the plant of the Glenn L. Martin Co. of Baltimore, Md. Discusses plant location, management, products, testing, plating, machinery, welding, tools, inspection, material handling, and a summary of equipment by departments. RHP(17)

Working Conditions Feature Layout of New Tool Plant. BURNHAM FINNEY. *Iron Age*, Vol. 126, Sept. 25, 1930, pages 849–853, 903–904.

Describes the new plant of Goddard & Goddard Co., Inc., Detroit. VSP(17)

Buys Strip for Steel Beds on Basis of Die Performance. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, May 8, 1930, pages 47–51.

Describes equipment and methods used in fabricating beds in the plants of the Simmons Co. Make welded tubes from cold-rolled strip steel. MS(17)

Forging Business Grows Under Alert Direction. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, March 13, 1930, pages 51–55.

Describes practice of the Camden Forge Co., Camden, N. J., which specializes in locomotive and marine forgings. Various parts are being nitrided. Steel used contains 0.32% C, 0.40–0.70% Mn, 0.20–0.30% Si, 1.00–1.25% Al, 1.50–1.75% Cr, 0.15–0.25% Mo, 0.03% and less S and P. When Cr is omitted, Al and Mo are raised to 1.5% and 1.0% respectively. The piece receives several heat treatments to remove all internal strains, before nitriding. The latter operation is carried out with NH_3 at a pressure of $1^1/_2$ in. H_2O in a Pb-sealed box. Temperature of nitriding is 950–1200° F., and duration of the process is 24–90 hrs. depending upon the depth and hardness of the case desired. MS(17)

Heat Treats Alloy Steel Side Frames. H. R. SIMONDS. *Steel*, Vol. 87, July 3, 1930, pages 51–53.

Describes practice of the Parish Pressed Steel Co., Reading, Pa., in the manufacture and treatment of side frames for trucks and busses. Frames are formed from a steel containing 0.23% C, 0.46% Mn, 0.05[sic]% Cr and 1.48% Ni; a Mn steel with 0.30% C and 1.52% Mn; or a C steel with 0.28% C and 0.45% Mn. Heat treating is done on a production basis. Use 40-ft. furnaces. MS(17)

Steel Foundry Reduces Cost of Cleaning Castings. H. R. SIMONDS. *Iron Trade Review*, Vol. 86, May 1, 1930, pages 114–118.

Eastern Steel Castings, Inc., Newark, N. J. has cut its cleaning costs more than one half by the installation of conveyors and new equipment and the adoption of piece rate and bonus system of compensation. Describes methods and equipment. MS(17)

The New Foundry of the Skoda Company. (Die neue Metallgiesserei der Aktiengesellschaft, vorm. Skoda Werke, Pilsen.) J. MEHRTENS. *Zeitschrift für Metallkunde*, Vol. 22, Sept. 1930, pages 304–307.

The Skoda Company's up-to-date foundry for non-ferrous metals and alloys is described and various views of the interior presented. EF(17)

Smelting at Coniston in Blast Furnaces. W. A. MacDonnell & J. F. Robertson (International Nickel Co.). *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1931, pages 478–479.

With the present improved smelting operations the monthly capacity of the Coniston plant of the International Nickel Co. is 75,000 tons of ore per month. WHB(17)

Automatic Zinc Plating and Enameling Pipe. *Metal Industry*, New York, Vol. 29, Mar. 1931, pages 113–115.

A description of a modern conduit pipe coating installation of Steel & Tubes, Inc., Warren, Ohio. There are produced, under the supervision of one man, 100 ft./min. of pipe with zinc electro deposited on outside and a baked enameled coat on inside. All is done in 17 operations which involve alkali soak, alkaline electrolytic cleaner, acid pickle and dip, zinc cyanide "strike," zinc sulphate "finish," enamel spraying and baking. PRK(17)

Pipe Zinc Plated and Enameled Automatically. *Brass World*, Vol. 27, Mar. 1931, pages 65–69.

A description of the plant of Steel & Tubes, Inc., at Warren, Ohio, where electrically welded conduit is produced. The machine's seventeen operations are listed. Cleaning, pickling, rinsing, galvanizing, enameling and baking are combined into a completely continuous process. WHB(17)

Steel Produced by Electric Furnaces in Modern Canadian Tube and Steel Plant Supersedes Older Methods. *Iron and Steel of Canada*, Vol. 14, Feb. 1931, pages 30–32.

An article describing the steel-melting installation of Canadian Tube and Steel Products, Limited, Montreal, Canada. OWE(17)

MACHINERY & SUPPLIES (18)

New German Wire Machinery. P. Fidrmuc. *Wire & Wire Products*, Vol. 5, Sept. 1930, pages 343–346, 365, 366.

Description of high-speed rope making and stranding machines with stationary spool carriers. GN(18)

Electric Equipment to Operate the Blast Furnace Skip Hoist. C. P. Hamilton (General Electric Co.). *Iron & Steel Engineer*, Vol. 8, Mar. 1931, pages 139–144.

A paper read before the Chicago District Section of the A. I. & S. E. E. Six general types of drives are considered and studies made of general operating conditions on the basis of reliability, maintenance, flexibility, power consumption, speed regulation and cost. Several figures and a brief discussion are included. WHB(18)

German Wire Mesh Machinery. P. Fidrmuc. *Wire & Wire Products*, Vol. 5, Dec. 1930, pages 462–463, 478.

The article describes a new type of mesh making machinery, recently put on the market by Emil Jager, Neustadt, Germany. GN(18)

Core Room Conveyors. D. B. Hill. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, July 1930, pages 273–288.

A description of mechanical installations for continuous baking and handling of cores. CHL(18)

Alternating Current Drives for Tube Mills and Reconstruction of a Strip Mill. (Drehstromantriebe von Rohrwalzwerken und Umbau einer Streifenstrasse.) W. Albrecht. *Stahl und Eisen*, Vol. 50, Oct. 16, 1931, pages 1457–1462.

Report 78 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The electric equipment and wiring diagram for driving the skew rolls of a tube rolling-mill are illustrated and described. The reconstruction of a strip mill, resulting in savings and increasing the capacity of the mill from 5.6 tons/hr. to 12 tons/hr., is also described. GN(18)

Roll Straightening Machine (Rollenrichtmaschinen für Walzwerkszurichterei). *Stahl und Eisen*, Vol. 50, Sept. 11, 1930, pages 1307–1308.

Illustrated description of a modern universal roll straightening machine built by A. Wirth & Co., Erkelenz, Germany. GN(18)

Device for Turning Forgings (Wendsvorrichtung für Schmiedestücke). *Stahl und Eisen*, Vol. 50, Aug. 28, 1930, pages 1234–1235.

Description of a simple device for turning bulky forgings, built by Deutsche Maschinenfabrik, Duisburg. GN(18)

Low Production of Hot Copper Rods without Loss of Economy. *Brass World*, Vol. 27, Mar. 1931, page 56.

A new type of hot mill for the production of copper rods at a rate well below that hitherto considered the economic minimum is manufactured by the United Engineering and Foundry Co., Pittsburgh, Pa. The layout is of the Belgian type consisting of roughing train, finishing train, reels, water bosh and the necessary tables and auxiliary. Profitable operation is possible with a production of no more than 10,000 lbs./hr. WHB(18)

MISCELLANEOUS (20)

Cleaning Stack Gases. John B. C. Kershaw. *Electrical World*, Vol. 97, Mar. 21, 1931, pages 542–546.

London power stations are washing the plant gases to eliminate dust and noxious gases. Three essentials to success for the treatment of flue gas are as follows: (1) the placing of sprays along the first flue to increase the humidity of the gases, with surfaces of iron to assist in converting SO_2 to SO_3, (2) the provision of further sprays and of wetted contact surfaces in the second flue to continue the conversion and to effect the solution of SO_3 and its elimination from the waste gases, and (3) the provision of further surfaces moistened with alkali for the total elimination of sulphur from the gas. The Battersea power station is planned to fulfil the conditions named. It permits the use of an over-all figure of 25 tons of water per ton of coal and the time of contact allowed for ranges from a minimum of 23 seconds to a maximum of 44 seconds. Corrugated plates of (a) staybrite, (b) calorized steel, (c) a silicon-aluminum alloy and (d) tinned iron are being tried out to secure the necessary catalytic action. A close-grain cast iron, or a silicon-cast iron will be used for all pipe work and an alloy of silicon and copper or of cast iron and monel metal will be used for the circulating pumps and other machinery in contact with the wash water, and sprays of the centrifugal type will be constructed of a silicon-copper alloy. Cost estimates for gas washing (36¢ per ton of coal burned) are considered high. Results of experimental trial of gas-washing plant at Grove Road Station of the London Power Co. in 1930 are tabulated. WHB(20)

REDUCTION METALLURGY (31)

Resistance of Iron Ores to Decrepitation and Mechanical Work. T. L. Joseph & E. P. Barrett (U. S. Bureau of Mines). *Transactions, American Institute of Mining & Metallurgical Engineers, Iron & Steel Division*, 1930, pages 365–377.

Includes bibliography of 53 references. The resistance of iron ores to decrepitation in a blast furnace was determined by screen analyses. The ores were samples, one portion rotated in a cold kiln for $1^1/_2$ hrs., and a second portion rotated in the kiln for the same time at 1400° F. The average decrease in particle size on cold working was 18%, and on the hot working 38.1%. Screen analyses on the raw ores do not indicate their propensity to form dust in the blast furnace, but the hot working tests do. Thirty odd ores, including Mn ores, were studied, and the results of the tests are given for each. Three samples of limestone were also studied. JLG(31)

Recovering Smelter Dust and Oxide. N. F. Kepner, W. Romanoff & C. O. Thieme. *Engineering & Mining Journal*, Vol. 131, Jan. 26, 1931, pages 60–64.

A brief description of the practice and equipment and technical control in the modern secondary-metal smelter of H. Kramer & Co., Chicago. The preparation of scrap for the smelting furnaces, and furnace operation are summarized. The dust collecting equipment is calculated to be of sufficient capacity to handle the gases and dust from 3 reverberatories or 2 furnaces and a 42-inch blast furnace operating simultaneously. Chrome-nickel-iron alloy flue branches and a manifold were necessary due to excessive temperatures. A spray chamber with water from a high-pressure pump was also necessary. A general layout of the flue system as far as the spray chamber illustrates the manner in which the branch flues lead to the manifold "A." Pyrometric control was found necessary to preserve the life of the high-temperature-resistant steel branches. WHB(31)

Suggested Improvements in Fire Refining of Copper. H. H. Alexander. *Engineering & Mining Journal*, Vol. 131, Mar. 9, 1931, pages 226–229.

An outline of methods incorporated in U. S. Patents 1,687,277, 1,756,967, and 1,776,826. Means of removing impurities by oxidation, the deoxidation of copper, and improved melting practice as tried out in the laboratory and in furnaces of commercial size are pointed out. Melting and refining simultaneously results in: low initial cost of equipment, lower slag production, few repairs, low operating cost and a better product. WHB(31)

Refining Nickel-Copper Matte at Port Colborne. R. L Peek. *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1931, pages 482–488.

A rather detailed description of the refining operations at the Port Colborne plant of the International Nickel Co. of Canada. WHB(31)

Effect of Particle Size on Flotation. A. W. Gaudin, John O. Groth & H. B. Henderson (Montana School of Mines). *Technical Publication* No. 414, *American Institute of Mining & Metallurgical Engineers*, 1931, 23 pages.

To determine the effect of particle size concentrates were obtained from several mills and samples were prepared by grinding minerals. There was found to be a time sequence with regard to particle size; the medium coarse particles floating first. No successful method of floating very fine pulp was found. Recovery is optimum in a well-defined range, and selection is optimum in another well defined range. In the mill concentrates the size for optimum recovery was between 280 and 560 mesh. 11 references. JLG(31)

Method and Cost of Recovering Quicksilver from Low-Grade Ore at the Reduction Plant of the Sulphur Bank Syndicate, Clearlake, California. Worthen Bradley. *Bureau of Mines Information Circular* 6429, 1931, 17 pages.

The ore deposit consists of grains of cinnabar finely disseminated throughout a gangue composed principally of altered basalt with subordinate amounts of elemental S (1–15%, average 2%) and opal. Recovery is as follows: (1) screening (cinnabar mostly in fines) and sorting the low-grade ore to obtain a furnace feed containing 8–10 lbs. of Hg per ton, (2) treatment in a rotary kiln, (3) precipitation of dust from gas stream, (4) condensing Hg from gas, (5) flotation of low-grade condenser mud, and (6) retorting high grade condenser mud and high-grade flotation concentrates. Costs per ton of ore treated for April 1930, are: screening and sorting $0.835, furnace treatment 1.709, flotation 0.387, retorting 0.177, assaying 0.107, condensing 0.534, miscellaneous 0.359, and total $4.108. AHE(31)

Flotation of Minor Gold in Large-Scale Copper Concentrators. E. S. Leaver & J. A. Woolf (U. S. Bureau of Mines). *Technical Publication* No. 410, *American Institute of Mining & Metallurgical Engineers*, 1931, 32 pages.

Ores from several mines were tested. The Au is usually included in the pyrite. The Au can be floated and the pyrite depressed with lime. Lime depresses the Au if the alkalinity is above 10 pH. An alkalinity of 7.5 to 10 was found desirable. Ores with a low ratio of pyrite to copper sulphide and with Au under $1 a ton gave a 25% Cu concentrate containing over 90% of the Cu and over 80% of the Au. Contains 2 references. JLG(31)

Arsenic Elimination in the Reverberatory Refining of Native Copper. C. T. Eddy (Michigan College of Mining and Technology). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 403, 1931, 16 pages.

The effect of As on the electrical conductivity of Lake Cu was determined. A study was made of the soda-ash method for the removal of As. In this process As can be most economically removed at an oxygen concentration of 0.85%. 7 references. JLG(31)

Reactions between Iron Sulfide, Sulfur Dioxide, and Iron Oxides in the Metallurgy of Copper. A. C. Halferdahl. *Industrial & Engineering Chemistry*, Vol. 22, Sept. 1930, pages 956–963.

41 references. Data and calculations are presented which indicate that magnetite is readily formed in smelting operations. Once formed, its reduction to ferrous oxide by ferrous sulphide required temperatures of 1300° C. or higher. A modification of present methods for treating copper converter slag in reverberatory furnaces is suggested. The function of coke in pyritic and semi-pyritic copper smelting is defined in a somewhat different manner than hitherto. MEH(31)

Treatment of Low-Grade Ores of Lead, Zinc and Tin. *Metallurgist*, Sept. 1930, pages 133–134.

The process developed in Germany for the utilization of low-grade ores of lead, zinc and tin is described. It is termed the "Wälzverfahren" or the "roll-over" process. The "rolling-over" occurs as the charge of ore with suitable admixtures, consisting chiefly of coke, passes down a long inclined rotary tube furnace of large dimensions, this rolling over bringing about an intimate mixture and continued disintegration of the material, which is said to determine the efficiency of the extraction. The extraction itself, however, takes place by volatilization and the production of an oxide or sulphide fume which is drawn from the furnace into condensing plant, in which it is recovered by one of the well-known methods, such as the electrical deposition after the manner of the Lodge-Cotterill process, or in bag filters, etc. The process has come into use in old-established districts in Germany where the ore is very low grade. A comprehensive account of the process in its recent state of development, together with references to still more detailed literature is to be found in an article by R. Hoffmann in the *Zeitschrift Verein deutscher Ingenieure*, Vol. 14, July 26, 1930, pages 1041–1048; see abstract in *Metals & Alloys*, Vol. 2, Jan. 1931, page 20. VVK(31)

Progress in the Development of the Wiluna Mine, W. A. *Chemical Engineering & Mining Review*, Vol. 23, Jan. 5, 1931, pages 136–139.

An illustrated description of this mine indicates the simplicity of the whole equipment and the very compact layout. The plant is the best laid out and best equipped gold mining unit in Australia. Ore treatment will comprise concentrating by flotation of the gold-bearing sulphides in a product 8–10% by weight of the original ore, roasting the flotation concentrate, and cyaniding the roasting calcine. A gyratory and two Symons cone crushers will crush the ore in two stages, to $^1/_2$ inch size. Hardinge conical ball mills followed by Ruwolt tube mills will operate in the fine-grinding section. Dorr bowl and rake classifiers will accomplish the classification. Before flotation, the ground pulp will be thickened in Dorr traction-type thickeners. In the flotation plant, power machines will be used for scavenging the tail and pneumatic machines to produce a clean concentrate. The flotation concentrate after thickening, will be filtered by Oliver continuous filters, dried on Lowden dryers, and roasted in Edwards-type roasters. Gold will be precipitated by the Merrill-Crowe vacuum. Pulp and water circuits will have Wilfley sand-type pumps. WHB(31)

Investigation on the Reduction Processes of Iron Ore. III. (Undersökning av förloppet vid reduktion av Järnmalm.) BERTIL STÅLHANE & TORE MALMBERG. *Jernkontorets Annaler*, Vol. 114, Dec. 15, 1930, pages 609–622.

The reduction of Kiruna magnetite in H_2 and H_2–CO mixtures has been investigated. At 950° C., 0.2 mm. grains were completely reduced by H_2 in 2 minutes; 2.0 mm. grains in 7 minutes and 4.0 mm. grains in 17 minutes. The rate falls off with temperature but there is a marked discontinuity at 910° C. at which temperature the time required is 2.5 times that at 890° C. Addition of CO to the H_2 slows up the rate quite markedly, the rate in 100% H_2 being 7 times as great as in 100% CO. Pure CO also gives the same discontinuity as H_2 at 910°. Mixtures show the same but less markedly. The temperature at which the reduction becomes exceedingly slow, 900° C. corresponds to the transition point of α-Fe to γ-Fe. HCD(31)

The Treatment of Hollinger Precipitate to Produce Fine Gold. MATTHEW SCOTT (Supt., Hollinger Refinery). *Canadian Mining & Metallurgical Bulletin* No. 228, April, 1931, pages 466–476.

Calcium cyanide is the solvent used. Au and Ag are precipitated by Zn dust and the Crowe vacuum process. To each ton of solution, 0.045 lb. of Zn and 0.01 lb. of Pb acetate are added. Almost 10% of the total Zn remains with the precipitate. These solutions are filtered. The precipitate analyses 39% moisture and on a dry basis, 35% Au, 7.2% Ag, 1.4% Cu, 9.3% Pb, 14.6% Zn, 0.3% Fe, 0.5% alumina, 11.7% lime, 0.7% silica and 4.4% S. Zn, lime, Pb (present as a sulphide), Fe and alumina are removed by hydrochloric acid treatment. The Au, Ag and Cu are separated by an adaptation of the sulphuric acid parting process. AHE(31)

The Progress of Metallurgy at Broken Hill, N. S. W. M. R. MCKEOWN. *Chemical Engineering & Mining Review*, Vol. 23, Dec. 5, 1930, pages 93–100.

Three great stages have marked the metallurgy of Broken Hill and recent developments point to the commencement of a fourth stage, which may have a very considerable influence on contemporary practice. The stages are: (1) gravity concentration for the production of an argentiferous galena concentrate, (2) gravity concentration for galena followed by flotation for the recovery of granular zinc blende, (3) gravity concentration for galena followed by selective flotation for recovery of galena and blende from granular de-leaded tailings and from slime, and (4) all-flotation for galena and zinc blende recovery. Several flow sheets and tables are shown. Recoveries of metals have advanced and it appears as though in the cases of Zn and Pb at Broken Hill the economic limits have been reached. The extended use of alkaline circuits may be expected to effect further economies and further developments in coarse flotation are probable. WHB(31)

Extraction of Metallic Bismuth and Lead-Tin Alloy from the Flue-Dust Collected in Cottrell Chambers at Ashio Mine. JURO SHIMONO. *Suiyokai-Shi. Transactions of the Mining & Metallurgical Alumni Association, Kyoto*, Vol. 6, No. 5, 1930, pages 405–462.

Outlines of the scheme have been quoted in the *Engineering & Mining Journal*, Vol. 128, 1929, page 89. Further details are given as to equipment, operations, preliminary trials in the laboratory and critical studies on the present operations, showing numerous tables. By a reducing fusion with soda ash, lime, charcoal and scrap Fe of the sinter from the As plant containing about 4% of Bi, 76% are collected in a fusible alloy. Admixture of galena is beneficial for materials of lower grades. The alloy, after having been purified by liquation, is cast into anodes and electrolyzed in a fluorsilicate bath to obtain simultaneous deposits of Pb and Sn at the cathode leaving Bi as a sponge adhering to the anode. Standard figures are as follows: total acid 16, Pb 2.6, and Sn 4 g./100 cc.; with small additions of colloid. Current density 2.5–3 amp./ft.^{2}, voltage 0.1–0.35 and temperature 10–28° C. Bi content of the anode should be less than 28%, or the porosity of the sponge is reduced, thereby increasing the polarization and the amount of Sn remaining. As the presence of As and Cu prevents Sn from being dissolved, complete removal is indispensable in the preceding operations. Equilibrium is stated to be attained between Pb and Sn ions when their concentrations are 3 and 4.5 g./100 cc., as in such a case electrolysis went on smoothly for several months without adjusting the composition of electrolyte. When the total acid falls below 16, Pb ion becomes rapidly impoverished and tin increases in the sponge. Higher current density also causes Pb and Sn ions to diminish. Analyses of different parts of the anode and the sponge are given together with some photomicrographs showing the structures of the electrodes and deposits. Bi sponge of the grade 95% is thus obtained, liquated, cast into anode and subjected to electrolysis, of which the standard figures are given as fluorsilicic acid 40 g./100 cc., Bi 4.5–5.0. Current density 3.5 amp./ft.^{2} Voltage 0.15–0.25. Temperature the same as the above. Small additions of colloid are also needed. Analysis of the Bi produced gave Bi—99.90%, Cu—0.05% and Fe—0.048%. As, Sb, Pb and Sn were not found. Pb Sn alloy consists of 89–90% Pb and 6–10% Sn and is sold as a material of antifriction metals. With rise in the Cottrell efficiency, Bi production increased remarkably of late to as much as 10,000 lbs./month and more than fulfills the demand of Japan. Details are given also as to the preparation and purification of the electrolytes. YO(31)

Improvements in the Metallurgy of Quicksilver. L. H. DUSCHAK. *Transactions American Institute of Mining and Metallurgical Engineers*, 1930, pages 283–298.

Direct furnace treatment is well adapted for extraction of Hg. The Scott furnace serves well. Rotary furnaces produce considerable dust. Low grade ores or tailings can be economically treated by wet screening and flotation. Cinnabar, reduced Hg, and synthetic sulphides are easy to concentrate by flotation. Leaching of ores does not appear to be promising. 3 references. JLG(31)

Reduction of Magnetite and Limonite with Methane (Die Reduktion von Magnetit und Limonit mit Methan). O. MEYER & W. EILENDER. *Archiv für Eisenhüttenwessen*, Vol. 4, Feb. 1931, pages 357–360.

Two iron ores were reduced with methane at various temperatures, times and gas velocities. The most favorable gas velocity in reducing was determined first. It is shown that the velocity of reduction increases with the gas velocity to a maximum, and decreases again. The ores were reduced at 800, 850, 900, 950, 1000 and 1050° C. and the time of reduction was increased in intervals of 15 min. The gas velocity amounted to 3 l./hr. The time of reduction has been plotted in diagrams against the degree of reduction for the various temperatures used. The course of the curves for both magnetite and limonite indicates that methane does not directly reduce the ore. Its decomposition products, carbon and hydrogen, are the reducing media. The decomposition of methane is catalyzed by metallic iron, unless a sufficient amount of metallic iron has been formed. The application of methane for the production of sponge iron is considered. This seems to be successful in the case of a partial combustion of the methane used. GN(31)

Benefication of Iron Ores. *Transactions, American Institute Mining & Metallurgical Engineers, Iron and Steel Division*, 1930, pages 407–431.

A "round table" discussion at Chicago on Sept. 22, 1930. Discussion mostly on concentration, but includes consideration of furnace operation and low temperature reduction. JLG(31)

The Present Status of Our Quicksilver Industry. CHARLES G. MAIER (U. S. Bureau of Mines). *Transactions, American Institute Mining & Metallurgical Engineers*, 1930, pages 299–316.

Includes discussion. A symposium introduced by a general discussion of mercury extraction by Maier. The Scott, rotary and hearth furnaces are compared. Monel condensers are suitable only if chlorides are absent from the furnace charge. JLG(31)

Recent Development in Blast-Furnace Design and Construction. ARTHUR G. MCKEE & WILLIAM HAVEN. *Transactions American Society Mechanical Engineers*, Vol. 52, Jan.–Apr. 1930, pages 13–19; Discussion pages 19–24.

This paper deals with 2 recent and highly important developments in blast-furnace construction and practice: the trend toward furnaces having daily capacities of 1000 tons or more, and the profitable utilization of blast-furnace gas in the firing of coke ovens, open-hearths, and in the various types of heating furnaces employed in steel mills. These developments have involved certain structural changes in the stacks, which have in time necessitated changes in such auxiliaries as stock-house and blowing equipment, gas cleaners, hot-blast stoves, and boilers. These are all considered in detail by the authors. (31)

Iron Ore from Pyrite. *Iron & Steel of Canada*, Vol. 14, Jan. 1931, pages 10–17.

Description of a new method of burning pyrite, which involves the use of the pyrite obtained as a by-product of the flotation process. This pyrite, being in a very finely-divided form, requires burning in a manner similar to pulverized coal. The iron oxides remaining after combustion may be looked upon as suitable for reduction, provided some sintering has taken place. OWE(31)

Amalgamation Practice at Porcupine United Gold Mines, Ltd., Timmins, Ontario. RONALD A. VARY. *Bureau of Mines Information Circular* 6433, Mar. 1931, 5 pages.

The ore consists of quartz with fine stringers of mineralized basaltic schist, or of banded quartz schist, or of stringers of quartz in schist, accompanied by pyrite and often containing visible gold. It is amalgamated in a 25-ton, pilot mill. Costs per ton of ore treated are crushing $0.384, grinding 0.771 classifying, screening, conveying and refining 0.626, miscellaneous 0.070 and total $1.851. AHE(31)

The New Smelter and Concentrator of the International Nickel Company at Copper Cliff, Ontario. L. M. SHERIDAN. *Engineering Journal of Canada*, Vol. 13, Nov. 1930, pages 682–687.

After coarse-crushing by hand at the mines, the ore is shipped to Copper Cliff where it is crushed to 200-mesh and sent through a wet concentration to remove the rock. In the concentration process the sulphides are floated, and the lighter rock material sinks to the bottom. By selective flotation a rough separation is made of the Cu and Ni. Smelting comprises roasting in multiple hearth roasters in reverberatory furnaces and blowing in basic-lined Bessemer converters. The product is an 80% Cu-Ni matte. The layout of the smelter and concentrator is shown in a diagram. WHB(31)

Cyanidation of a Copper-Gold Ore. E. H. SMITH. *Canadian Chemistry & Metallurgy*, Vol. 15, Feb. 1931, pages 45–46.

The function of lime in cyanidation of gold ores is attracting much attention. Lime and alkalinity have no solvent action on the precious metals but enter into numerous reactions occurring in the process. A pyritic ore ground in lime solution yields calcium sulphide and calcium thiosulphate and gangue constituents consume a certain amount of lime. Each mineral in an ore removes lime from the mill solution in an amount dependent on the lime present and this amount is specific for each mineral. Lime decomposes the zinc cyanide or double cyanide formed in the precipitation processes. WHB(31)

Vanadium Recovery at Rhodesian Broken Hill. *Engineering & Mining Journal*, Vol. 131, Mar. 23, 1931, page 259.

R. H. Stevens and his staff have developed a process providing for the complete removal of Va from the electrolyte and permits its recovery. Va dissolves during the process of extracting Zn from the ore and must be removed. The Va is precipitated as Zn or Fe vanadate and a mixture of the two. The precipitate is caught in a filter press, washed to remove soluble Zn and discharged to a storage bin. Filtrate and wash water are returned to the Zn circuit. The precipitate is converted to a slurry pumped to storage tanks, agitated, and withdrawn as needed in the first step of the recovery process, in which Va is dissolved in a 7.5% caustic soda solution (prepared by treating sodium carbonate with burnt lime). The slurry and caustic solutions in definite proportions are agitated 1–2 hours at 100° C. in a steam-heated iron vat. Va dissolves as sodium vanadate Fe and most of the Zn remain insoluble. The pulp is filtered in a press, washed, broken up in a pug mill, and discharged to an agitator where the solids are suspended in Zn solution and pumped back to the Zn circuit. In the precipitation tanks Va hydrate is precipitated by the addition of sulphuric acid till an excess of 5 g. per liter of free acid is present. Excess acid lowers efficiency but gives a purer product. Va hydrate is filtered in a filter press and washed counter currently in the strongest wash water, being returned to the precipitation circuit. The cake is fed to a gas fired furnace where free and combined moisture are eliminated with the dehydrated oxide fused. Impurities consist of alkalies and small amounts of silica and Fe. The Va oxide (V_2O_5) is 90–95% pure. WHB(31)

WANTED

HALF-TON ELECTRIC MELTING FURNACE, COMPLETE. GIVE DESCRIPTION AND PRICE IN FIRST LETTER. BOX F, Metal & Alloys, 3619 Forbes St., Pittsburgh, Pa.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

701 **Cold Rolled Strip Steel.**—Anyone who does not realize what an important part this product plays in our life should send for Bulletin No. 3 of the American Steel & Wire Company, 208 La Salle St., Chicago, Ill. Several pages are given over to illustrations of everyday applications of cold rolled strip steel and these will suggest many more. A table showing the approximate weight of 1000 feet of cold rolled flat steel wire of different widths is appended.

702 **AGA 1931-2.**—The American Gas Association, 420 Lexington Ave., New York, N. Y., presents its industrial advertising campaign in a most attractive portfolio. The series has been divided into advertisements for each of the most important industrial users of gas heat and anyone wishing to use them as enclosures imprinted with his own name and address may readily secure reprints or electrotypes.

703 **Thermometals.**—The Wilco Thermometals are duplex or bimetals. They consist of two metals with different rates of thermal expansion permanently bonded throughout their contact surfaces. Due to the difference in expansion of the members a change in temperature causes the bimetal to bend or deflect. It is this deflection which is utilized in the application of these metals to controls and indicating devices. A bulletin describing these metals is issued by the H. A. Wilson Co., 97 Chestnut St., Newark, N. J.

704 **Nickel-Clad Steel Plate.**—This plate provides the corrosion-resistance of pure nickel for heavy plate construction at economical cost. It withstands vacuum, severe vibration, mechanical shock, high temperatures and changes in pressure. The Lukens Steel Company, Coatesville, Pa., has sent out a number of descriptive pieces of literature about this product, among them being a reprint of an article, "Nickel-Clad Steel Plate Work," from *Mining & Metallurgy*.

705 **Grinding.**—The April issue of *Grits & Grinds*, published by the Norton Company, Worcester, Mass., features an article entitled "Grinding Pump Shafts," by H. A. Charles. It also contains several other articles on problems and developments in the grinding field.

706 **Cobaltcrom PRK 33.**—The latest booklet of the Darwin & Milner, Inc., 1260 West 4th St., Cleveland, Ohio, is devoted to a description of the physical properties of this alloy steel, which can be used for dies of all kinds, shear-blades, shearing press tools, etc.

707 **The Laboratory.**—The Vol. 4, No. 3, issue of this periodical published by the Fisher Scientific Company, Pittsburgh, Pa., describes several new instruments for the laboratory. One is a new vacuum still which permits liquids to be distilled at $^1/_2$-10 mm. Hg pressure with a new accuracy. Another is a new hand refractometer for measuring sugar content.

708 **Potentiometer Pyrometer.**—The Brown Instrument Co., Philadelphia, Pa., has published a new Catalog No. 1101, a 48-page book, well illustrated, with descriptions of fifty features of their new line of potentiometer pyrometers. The instrument has a broad application to industrial needs involving the measurement and control of temperatures, especially in the higher ranges.

709 **Welding.**—A 16-page publication entitled "Westinghouse Arc Welding Data Bulletin No. 15," has recently been announced by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. This booklet contains illustrations of some unusual arc welding achievements, explains with the aid of diagrams various methods of testing, and discusses methods for obtaining good welds. In this connection they have also published a leaflet, L-20518, describing the construction, operation and application of their Flex-Arc 600-Ampere welder.

710 **Material Handling.**—The Link-Belt Company, 910 S. Michigan Ave., Chicago, Ill., has sent out the second Data Sheet in their series on Material Handling & Power Transmission. This one is entitled "Belt Conveyor Horse Power and Stress." These data sheets cover important phases of the subjects about which little has been published.

711 **Recording Gages.**—Bulletin 168 of the Foxboro Company, Foxboro, Mass., describes their modern gages which have an alloy-steel helical spring with welded steel connections. This material for gage springs has been used successfully for three years under all kinds of conditions. It combines safety with accuracy. This bulletin is a well-illustrated booklet of 23 pages.

712 **Sand Control.**—The June issue of *Better Methods* published by the Beardsley & Piper Co., Chicago, Ill., features an article entitled "Control of Sand Is As Important as Control of Metal in the Foundry." About 20 examples of defects in castings caused by improper molding sand and core practice are shown and remedies are offered.

713 **Heat-Treating Furnaces.**—Three leaflets have been prepared by the W. S. Rockwell Co., 50 Church St., New York, N. Y., which discuss different types of their heat-treating furnaces. No. 297 is devoted to their rotary type, electric and fuel, for ferrous and non-ferrous metals. No. 285 discusses the car and car-and-roll type, either electric or fuel, which is advantageously used for heating large and irregularly-shaped forgings or castings. No. 302 illustrates the continuous strand furnace which is electrically heated with automatic control. This furnace can also be arranged to clean the material.

714 **Hydrogen Ion Concentration Measurements.**—Catalog 75, issued by the Leeds & Northrup Company, Philadelphia, Pa., lists apparatus for determining hydrogen ion concentrations of solutions by the null potentiometer method. The descriptions of the various potentiometers indicate the conditions for which each one is most suitable, and the accuracy of which each one is capable in those conditions. Equipments for automatic measurement and control of acidity and alkalinity are also included. Their catalog No. 84 describes potentiometers for automatic temperature control.

715 **Nickel Alloy Steels in Airplane Engines.**—A 12-page booklet sent out by the International Nickel Company, 67 Wall St., New York, N. Y., gives a discussion of the principal features and service records of the complete Curtiss and Wright lines of airplane engines, with special reference to materials used in their construction. Numerous illustrations are included showing views of the different engine models, of important parts, and of planes in which these engines are installed.

716 **Rare Metals.**—The Fansteel Products Co., Inc., North Chicago, Ill., has prepared a new edition of their 72-page book entitled "Rare Metals." This is to give one an idea of the possibilities inherent in little-known metals and alloys that promise to alter the course of many industries. Tantalum, tungsten and molybdenum are the metals under discussion.

717 **Arc-Welding.**—Leaflet GEA-823C, of the General Electric Company, Schenectady, N. Y., describes their atomic-hydrogen arc-welding equipment for hand welding on 50- and 60-cycle circuits. This process of welding with hydrogen by continuous independent arc produces homogeneous, ductile welds on ferrous and non-ferrous metals and alloys.

718 **Copper and Brass.**—The June issue of the Bulletin of the Copper & Brass Research Association, 25 Broadway, New York, N. Y., illustrates a number of unique uses for these metals, some practical and some decorative.

719 **The Modern Soaking Pit.**—The Surface Combustion Corporation, Toledo, Ohio, has gotten out a particularly attractive and unusual booklet on soaking pits designed and installed by them. Layouts contrasting the old and modern types are shown. The latter is a one-way fired pit which saves building cost and allows a much more convenient arrangement.

720 **Udyblack.**—The Udylite Process Co., 30 East 42nd St., New York, N. Y., has developed a new black cadmium plating process. Particularly attractive results have been obtained on cast surfaces and on sand blasted forgings. An interesting account of this process and its applications will be found in the June 1931 issue of the Udylite News. This company has also prepared a folder on their cadmium plating process which is an exposition of the theory and practice of the science and art of electrolytic application of cadmium.

721 **Steel Castings.**—The Sivyer Steel Castings Co., Milwaukee, Wis. has compiled two useful little books, one entitled "Dependability in Steel Castings" and the other, "Steel Casting Patterns." The first of these discusses briefly the various steps in the process of making a steel casting, and describes the methods used to maintain steel casting dependability. The second tells about the construction of patterns, and standard foundry practice in reference to them.

722 **Magnesium.**—The Dow Chemical Co., Midland, Mich., has prepared a reprint of an article entitled "Magnesium, Industry's Lightest Structural Metal" by John A. Gann. In it are given a history of magnesium, foundry practice in the production of magnesium and magnesium-alloy castings, their heat-treatment and applications.

CURRENT METALLURGICAL LITERATURE ABSTRACTS OF METALS & ALLOYS

PUBLISHED MONTHLY BY THE CHEMICAL CATALOG COMPANY, INC.
419 Fourth Ave., New York
Editorial and Advertising Offices: 3619 Forbes Street, Pittsburgh, Pa.
Annual Subscriptions: U. S., Possessions, Mexico and Cuba, $3.00; Canada, $3.50; Other Countries, $4.00; Single copies, 40¢.
Copyright, 1931, by The Chemical Catalog Company, Inc. All rights reserved.

Note. The September issue of METALS & ALLOYS will be Vol. 2, No. 3. For purposes of binding and filing, these monthly bulletins may be considered as Vol. 2, No. 2a, 2b, etc

These abstracts are not critical, but merely review developments. The classification number at the end of each abstract will be of assistance in mounting them on filing cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class.
The remittance should accompany the order.
Book Reviews are included below and marked by -B-

PATENT SERVICE

Until we resume regular publication in September, the service rendered by the Patent Department of METALS & ALLOYS will be carried on by Mr. W. M. Corse, 81. Eighteenth Street, Washington, D. C., who can supply copies of United States and foreign patents and translations at reasonable costs.

PROPERTIES OF FERROUS ALLOYS (3)

Chrome-Manganese Steels. FREDRICK M. BECKET. *Yearbook American Iron & Steel Institute*, 1930, pages 173–194.
Includes discussion. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 900. (3)

Properties and Application of Nickel and Nickel Chromium Steels. (Proprietes et applications des aciers au nickel et au nickel chrome.) J. GALIBOURG. *Revue de Metallurgie*, Vol. 28, Jan. 1931, pages 30–39; Feb. 1931, pages 85–100, 35 references.
A review of the properties of plain carbon, nickel, nickel chromium and stainless Ni-Cr alloys. JDG(3)

Heat- and Acid-Resisting Cast Irons with High Chromium and Carbon Contents. EMANUEL VALENTA. *Carnegie Scholarship Memoirs, Iron & Steel Institute*, Vol. 19, 1930, pages 79–165.
Paper received June 11, 1929 contains 40 references. A résumé of previous studies is followed by description of melting technique in preparation of alloys of this study. Analyses of 73 alloys of Fe-Cr-C with and without additions of Si and Al are given and their hardness for various thicknesses as cast, hardness as cast, as annealed at 1000° C. for 4 hours cooled slowly, and as air quenched from 1000° C. are tabulated and shown graphically. A discussion of micro- and macro-structures of these alloys is illustrated by 52 photographs. A study of the phase changes by quenching and dilatometric methods was made. Volume changes in these alloys at high temperatures were determined and results shown in graphical form. WLC(3)

A Heat- and Corrosion-Resisting Cast Iron. *Nickel Bulletin*, Vol. 3, Nov. 1930, pages 354–356.
New alloy contains about 75% cast iron, 4% Cr and remainder monel metal. Named "Nimol." Properties and suggested uses are given. MFB(3)

Properties of Spring Wire. (Beurteilung von naturharten Federdrähten.) K. THOMSEN. *Krupp'sche Monatshefte*, Vol. 11, Nov. 1930, pages 291–292.
The article considers in a general manner the tests to be made for passing judgment on the qualifications of steel spring wire. Brief description of the experiments of the Kaiser Wilhelm Institut für Eisenforschung on the determination of the elastic limit and the yield point by means of the torsion test. In testing basic open hearth steel wire of various compositions, heat treatment and drawing practice, it was found that the ratio between elastic limit, yield point and tensile strength is independent of the above factors. Similar experiments on acid open hearth steel are in progress. After blue annealing, the above ratio is changed to higher values, since blue annealing increases the elastic limit and the yield point to a larger extent than it increases the tensile strength. Zinc coated wires have a decreased ratio between yield point and tensile strength; they, therefore, are less elastic. Reference to the elastic properties of KA2 wire is made. Quality and suitability of spring wire can be judged satisfactorily by the tensile strength. GN(3)

Corrosion and Heat Resistant Nickel-Copper-Chromium Cast Iron. J. S. VANICK & P. D. MERICA. *Iron & Steel of Canada*, Vol. 13, Nov. 1930, pages 241–260.
Description of heat-resistant cast iron having the following analysis:

	Min.	Max.
Total carbon	2.75%	3.10%
Silicon	1.25	2.00
Sulphur	0.04	0.120
Phosphorus	0.04	0.30
Manganese	1.00	1.50
Nickel	12.00	15.00
Copper	5.00	7.00
Chromium	1.50	4.00

This has been investigated thoroughly in the laboratories of the International Nickel Co. and in the field during the past 3 or 4 years. The article deals with the applications of this material, with its development, with its mechanical properties, and with others of its physical characteristics. OWE(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosion with Reference to Boilers. T. MILLICAN. *Advance Copy, North-East Coast Institution of Engineers & Shipbuilders*, Mar. 20, 1931, 14 pages.
The paper deals with various theories which have been advanced in explanation of the causes of corrosion, some of these theories being supplemented or altered in light of recent research. Effects are shown to be of various forms but that form which is most destructive to boiler plates is, unfortunately, pitting, which is that most generally met with. It is shown that where incrustation is allowed to form on the boiler heating surfaces there is a definite tendency to support corrosion due to differential aeration. Mention is made of a case considered unusual, but which might prove not be so unusual if investigation were more universally thorough, where decarburization of the surface of the metal was found to be due to overheating. Cases of corrosion in general are considered in respect to those types of boilers most commonly met with in practice and although methods of prevention are mentioned, having due regard to the danger of producing conditions which may give rise to caustic embrittlement, it is considered that probably each case of corrosion is a law unto itself and should receive thorough individual investigation. (4)

The Potential of Passive Iron. (Sur le potential du fer passif.) A. TRAVERS & J. AUBERT. *Comptes Rendus de L'Academie des Sciences*, Vol. 192, Jan. 19, 1931, pages 161–163.
The authors describe their experiments on the potential of passivated iron in various media, from the results of which they conclude that the expression "passive iron" is in no sense absolute in view of the fact that there are degrees of passivity, that it appears difficult to assume Evans's hypothesis of a film of oxide in all cases of passivation in view of the fact that the potential of iron immersed in various oxidizing agents varies according to the agent, and that values for the potential of metals susceptible to passivation (e. g., iron) depend essentially on the conditions in which the metals are placed. OWE(4)

Resistance of Metals to the System Urea–Water–Ammonium Carbamate. J. G. THOMPSON, H. J. KRASE & K. G. CLARK (Fertilizer and Fixed Nitrogen Investigations, Bureau of Chemistry and Soils, Washington, D. C.). *Industrial & Engineering Chemistry*, Vol. 22, July 1930, pages 735–736.
The results of tests on 36 metals and alloys are tabulated. MEH(4)

Corrosion Resistance of Light Alloys. H. SUTTON (Royal Aircraft Establishment, England). *First Communications of the New International Association for the Testing of Materials.* Group A, Zurich, 1930, pages 304–308, 19 references.
A list of English investigations on the subject with very brief comment on the results. Anodic treatment is advocated for aluminum alloys. No effective protection for magnesium alloys is yet known. Corrosion-fatigue studies on Al and Mg alloys are under way at the Royal Aircraft Establishment and the National Physical Laboratory. HWG(4)

The Rate of Solution of Magnesium in Acids. MARTIN KILPATRICK, JR. & J. HENRY RUSHTON. *Journal of Physical Chemistry*, Vol. 34, Oct. 1930, pages 2180–2186.
The preliminary report of an investigation of the rate of solution of metals in acids in aqueous and non-aqueous solution, from the standpoint of Brönsted's theory of acids and bases, which is likely to be of importance in the study of corrosion. The particular experiments described were designed to answer the question whether magnesium in formate-formic acid buffer solutions reacts with the acid H_3O^+ (hydrogen-ion), the existence of which is postulated by Brönsted, with the acid HCOOH, or with both. It is shown that the reaction with molecular formic acid predominates. Experiments with other solutions are dealt with. OWE(4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

The Study of Special Steels—Constitutional Diagram of the 18% Cr Alloys with Variable Composition of Nickel and Carbon. V. N. KRIVOBOK. *Mining & Metallurgical Investigations U. S. Bureau of Mines & Carnegie Institute of Technology, Mining & Metallurgical Advisory Boards*, 4th Open Meeting, Oct. 17, 1930, 4 pages.

An outline of problems begun or to be carried out on 18% Cr-Fe alloys containing variable percentages of Ni and C is given. (5a)

Relations between Structure and Properties in Metallic Alloys. (Die Zusammenhänge zwischen Aufbau und Eigenschaften der Metall-Legierungen.) A. GUERTLER (Tech. Hochschule, Berlin-Charlottenburg). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 320–327.

Philosophical discussion of individual crystals of pure metals, of compounds, of solid solutions and aggregates. The article does not lend itself to condensation. HWG(5a)

Solidus Determination by Means of Heating Curves. J. H. ANDREW & H. NCNEIL. *Metallurgist*, Oct. 1929, pages 154–155.

Review of a paper in the *Journal of the Royal Technical College*. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 793. (5a)

Constitutional Diagram of Iron-Manganese Alloys. V. N. KRIVOBOK. *Mining & Metallurgical Investigations, U. S. Bureau of Mines & Carnegie Institute of Technology, Mining & Metallurgical Advisory Boards*, 4th Open Meeting, Oct. 17, 1930, 3 pages.

Tentative constitutional diagram was constructed from data supplied by thermal analysis, metallographic studies and X-ray patterns. It is believed there are at least 6 different phases: α-Fe, γ-Fe, ϵ-Fe, α-Mn, β-Mn and γ-Mn. (5a)

The Mode of Deformation of a Single Crystal of Silver. H. J. GOUGH & H. L. COX (National Physical Laboratory). *Institute of Metals, Advance Copy* No. 552, 1931, 18 pages.

A single crystal of Ag was subjected to alternating torsional stresses and the surface examined to determine the mechanism of deformation. Numerous slip bands were formed on the octahedral planes, but there was no definite evidence of twinning even when the stresses were applied until failure. The slip bands might have been narrow twins, but this appears to be improbable. No twins could be produced by compression. Because of the ease with which twinning occurs in an aggregate of small crystals, the mechanism of deformation in a single crystal must be essentially different from that in the aggregate. 7 references. JLG(5a)

Constitution of Light Magnesium-Copper Alloys. (Ricerche sopra la costituzione delle leghe rame-magnesio ricche in magnesio.) F. DE CARLI (Instituto Chimico R. Universita, Rome). *La Metallurgia Italiana*, Vol. 23, Jan. 1931, pages 18–21, 13 references.

Electrical resistance at 20°, 40°, 60°, 80°, 100°, 150°, 200° and 250° C. was determined on Mg alloys with 0.09, 0.28, 0.98, 2.5 and 5.4% Cu. From this it was concluded that the limit of solid solution of Cu in Mg is about 0.1% Cu at room temperature, varying slightly with temperature, perhaps approaching 0.2% Cu at 250° C. Specimens of compositions between 0.09 and 0.28% Cu were lacking; so the results are not very definite. HWG(5a)

Contribution to the Problem of Primary Crystallization. (Beiträge zur Frage der Primärkristallisation.) F. R. HENSEL (Doktor-Ingenieur dissertation). Technische Hochschule, Berlin, Jan. 1929, 38 pages. Published by Giesserei-Verlag, Düsseldorf. 72 references, 46 tables, 91 figures.

The orientation of the crystals in the transcrystalline zone in silicon steel was studied by several methods. A great number of castings of tin were made in ingot molds of various dimensions, the ingots sectioned, macro-etched and photographs shown, with tables describing the casting conditions. Other tests were made on silicon steel, lead, zinc and wax. Impurities in tin alter the macro-structure materially. Special experiments indicated that there is no undercooling in tin, and that the various zones of crystallization cannot be explained on the undercooling theory. No other very definite conclusions were reached, although a vast amount of work is recorded. Part of the work was done under Professor Desch at Sheffield, part under Professor Guertler in Berlin.—H. W. Gillett (5a)-B-

The Molecular Constitution of the α-Solid Solutions of Tin in Copper and of the Corresponding Liquid Solutions Examined Thermodynamically. F. H. JEFFERY. *Transactions Faraday Society*, Vol. 27, March 1931, pages 136–137.

Using the results of Raper and of Stockdale and of Heycock and Neville, it was shown by the thermodynamic method that in the Cu–Sn system, the α-solid solution consists of Cu_4Sn dissolved in monatomic Cu molecules. The liquid solution consists of Cu_4Sn dissolved in liquid Cu, the molecules of Cu being monatomic. PRK(5a)

The Molecular Constitution of the β-Solid Solutions of Tin in Copper Examined Thermodynamically. F. H. JEFFERY. *Transactions Faraday Society*, Vol. 27, March 1931, pages 137–139.

By slightly modifying the equilibrium diagram of the Cu–Sn system using the results of Raper and of Stockdale, evidence is afforded that the β-phase is a solid solution of monatomic Sn molecules in monatomic Cu molecules. PRK(5a)

The Microscope as a Practical Aid in the Cast Iron Foundry. ROY M. ALLEN. *American Foundrymen's Association, Preprint* No. 31–6, 1931, 84 pages.

The paper deals with the use of the microscope in studying cast iron from the point of view of providing information for the practical foundryman and young metallurgist. Effects of Si, S, P and Mn are discussed in detail. CHL(5a)

Silumin and Its Structure (Supplement). B. OTANI. *Kinzoku no Kenkyu*, Dec. 1930, pages 666–686.

The author's previous conclusion (Science Report of Tohoku Imperial University, Sendai, Vol. 15, 1926, page 679; *Journal Institute of Metals*, 36–2, 1926, page 243) on the mechanism of structure of silumin, i. e., Na solidifies by monotecto-eutectic reaction in the ternary system Al–Si–Na and consequently produces a modified fine structure of silumin, was confirmed by other ternary systems which undergo monotecto-eutectic reactions. Bi and Cd which undergo a monotectic reaction in the binary systems Bi–Al, Bi–Si, Cd–Al and Cd–Si was employed instead of Na. The addition of 0.5% of Bi shifts the eutectic point of Al–Si system by 2% to the Si side and any appreciable lowering or under-cooling of the eutectic temperature did not occur. The structure of the alloys thus obtained is finer than that of unmodified alloys, but it is a little coarser than that in the case of Na. By using Cd a similar result was obtained. Then Ni and Mg, which form a ternary eutectic with Al and Si, respectively, were examined. The eutectic points were 10° to 30° C. lower than that of the Al–Si system and did not show any under-cooling. But the structures were fine. Thus, the author showed the uncorrectness of under-cooling theory of silumin. Moreover Cr, Fe and Ca were also tested. The mechanical properties of all these alloys were examined and showed the correctness of the author's theory. KT(5a)

A Note on the Silver-Rich Aluminium-Silver Alloys above 600° C. T. P. HOAR & R. K. ROWNTREE (Cambridge). *Institute of Metals, Advance Copy* No. 555, 1931, 6 pages.

Alloys up to 15% Al were studied by thermal and microscopic methods. The results substantiate Petrenko's diagram except that the diagram is shifted to higher temperatures. The diagram is similar to the Cu-Al diagram. Contains 2 references. JLG(5a)

Constitution of Copper-Tin Alloys. SAMUEL L. HOYT. *Metal Progress*, Vol. 1, Sept. 1930, pages 104–106, 114.

(Recommended Practice Committee Releases, A. S. S. T.) A brief review of the work of various investigators in this field. Eleven references and a constitutional diagram of the tin-rich field are included. WHK(5a)

Recent Advances in Metallography. J. L. HAUGHTON (National Physical Laboratory, England). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 316–319.

Brief and extremely general comment on the services of metallography to metallurgy. Expresses the opinion that the question of the allotropy of zinc is not yet conclusively answered, but concedes that the purer the metal, the less marked are the indications of allotropy. HWG(5a)

Iron–Carbon System. (Le systeme fer-carbone.) EUGENE L. DUPUY. *Revue de Metallurgie*, Vol. 27, Dec. 1930, pages 686–692.

Historical review of the development of Fe-C equilibrium diagram, starting with Tchernoff, and its contemporary interpretation. JDG(5a)

Microscopic Investigation of Metals. V. N. KRIVOBOK. *Proceedings Engineers' Society of Western Pennsylvania*, Vol. 47, Feb. 1931, pages 45–62.

A non-technical review emphasizing the purposes of metallurgy, and the specific uses of metallography related thereto. With regard to inspection of metals and alloys, microscopic studies reveal the characteristics, the previous history of the sample and its suitability for a given purpose—but only when the sample is properly prepared by an experienced operator. This is illustrated by 7 microphotographs. The second phase of the metallographist's work is the inspection and investigation of material after a failure has occurred. Under the third category of work, the author discusses the development of new materials, and the illustrations show how to recognize definite changes in properties. The fourth function dealt with is true research or scientific metallography, under which 5 illustrations of martensite decomposition are discussed. MFB(5a)

The Structures of the High Chromium Stainless Steels and Irons. EDGAR C. BAIN. *Yearbook American Iron & Steel Institute*, 1930, pages 271–308.

Includes discussion. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 34. (5a)

On the Constitution of the Fe–C–Si System. Part II. Section through the Tridimensional Diagram at 8% Si. A. KRIZ & F. POBORIL. *Collection of Czechoslovak Chemical Communications*, Vol. 3, Jan./Feb. 1931, pages 61–72.

The properties of 7 alloys were investigated. These alloys were prepared by melting in an electric resistance furnace. The chemical composition of the alloys tested is given as follows:

Alloy No.	%C	%Mn	%Si	%P	%S	Ac_2 ° C.
34	0.14	0.43	7.97	0.041	0.011	645
35	0.21	0.31	7.87	0.045	0.011	660
36	0.34	0.40	7.63	0.062	0.015	645
37	0.50	0.48	8.12	0.038	0.016	650
38	0.86	0.38	7.94	0.062	0.023	650
39	1.88	0.46	7.45	0.052	0.024	665
40	2.7	0.55	7.84	0.097	0.009	665

Samples for thermal analysis and microscopic examination after heat treatment were taken from each alloy. Constitutional diagram of the ternary Fe–C–Si system containing 8% Si is given. The region of the homogeneous γ-phase does not exist in these alloys. The pearlitic transformation of the alloys with more than 0.48% C ends at the beginning of melting. The transformation Ac_2 in the alloys with 8% Si lies in the region $\alpha + C$ at 665° C. GTM(5a)

Structure & X-ray Analysis (5b)

Theory and Practice of X-Ray Analysis. WILLIAM H. BARNES (McGill University). *Canadian Chemistry & Metallurgy*, Vol. 15, Mar. 1931, pages 67–70.

A short review with brief mention of some of the fundamental conceptions on which the subject is based and an outline of a few of the fields of application. The production, nature of X-radiation and physical, chemical and biological effects thereof. Applications to spectroscopy and crystallography are noted. WHB(5b)

Technological Reflections on the X-Ray Testing of Materials. II. (Versuchstechnische Betrachtungen über die Material-Röntgenprüfung. II.) A. HERR. *Mitteilungen des Staatlichen Technischen Versuchsamtes in Wien*, Vol. 19, 1931, pages 60–78.

The author gives a survey of the methods of testing materials for defects with X-rays during the manufacturing process and on the finished product. In particular, he describes the possibilities, not only of finding that there are defects, but also of locating and determining exactly the extent of the defects from the X-ray photographs. Two methods are available to-day: one is the densographic method by von Schwarz, which determines the kind of defect from the blackness of the exposed film (negative); the other method is to locate the defect by measurement on 2 stereoscopic photographs. The apparatus and procedures are described in detail. A table giving the exposure times at different thicknesses of the material and the required voltage across the X-ray tube is added and the arrangement of the apparatus in tests on welded boilers, bridges, etc., is illustrated. The modern X-ray apparatus and safety arrangements against touching are also discussed and illustrations are given. 20 references supplement the very comprehensive paper. Ha(5b)

Gamma Rays in the Power Field. ROBERT F. MEHL & CHARLES S. BARRETT. *Power*, Vol. 73, Feb. 24, 1931, pages 340–432.

Gamma rays, emitted by radioactive substances, are as penetrating as X-rays from tubes operating at one or two million volts (ordinary industrial X-ray tubes require one to two hundred thousand volts). In use a small metal capsule containing the radioactive element is supported on a simple stand in front of the object to be tested and ordinary X-ray film in a light tight container is fastened on the opposite side of the object. Gamma ray radiographs have been taken through 6, 8 and 10 inches of steel while the limit of X-rays is $3^1/_2$ to $4^1/_2$ inches. Proper precautions must be taken to protect the operator. Radium is coming into use for inspection of large castings. A stern post weighing nine tons for a U. S. Navy cruiser, was examined, after installation by this method for internal defects, and numerous defects were found. On final trial the casting split in two requiring a complete replacement at a cost of $200,000. Such disasters can be prevented by γ-ray examination. A brief review of the characteristics of γ-rays is given. VVK(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Calibration of Testing Machines. (Eichung der Prüfmittel.) W. ERMLICH (Staatliches Materialprüfungsamt, Berlin). *First Communications of the New International Association for Testing Materials.* 1930, Group D, pages 173–181, 4 references.

Advocates use of standard test pieces or proving rings, used with a Martens' extensometer for calibration. Precise measurements show that the extension of a steel specimen within the proportional limit does not exactly follow a straight line Hooke's law curve. HWG(6)

Accuracy of Measurement and Variability of Test Results. F. C. LEA (University of Sheffield). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 198–204.

The more accurate the measurement, the less likely it is that the stress-strain diagram will be a straight line within the proportional limit. Hence, a definite strain should be set as the value to report for proportional limit instead of the first deviation from a straight line. This might be 0.001%. Similarly, yield point should be stated in terms of some arbitrary permanent strain. Below 600° C. the "limiting creep stress" in high temperature testing can probably be determined within 10%. Endurance tests carried to 10 million cycles should be within 5% of the truth. If the material requires more than 10 million cycles to show an endurance limit, it will ordinarily not be more than another 5% lower than the stress to give 10 million cycles unbroken. It is doubtful if indentation hardness figures can be stated within a probable error of 2%. The probable errors of weighing in good testing machines are less than 1%. HWG(6)

The Calibration of Testing Machines and the Variability and Attainable Accuracy of Testing Results. G. H. GULLIVER (D. Kirkaldy & Son, London.) *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 194–197.

Brief general discussion. HWG(6)

Volume Changes of Steel During Elastic and Non-elastic Deformation. (Ueber die Volumenänderung des Stahles bei elastischer und bildsamer Beanspruchung.) H. HANEMANN & R. YAMADA. *Archiv für Eisenhüttenwesen*, Vol. 4, Jan. 1931, pages 353–356; *Stahl und Eisen*, Vol. 51, Feb. 19, 1931, pages 225–226.

The mathematical principles of the testing equipment and a description of it are given. In increasing the load of the tensile testing machine, the changes of length and diameter of the test bars were determined and used to calculate the changes of volume. The tests were carried on on soft steel, annealed or pre-deformed 5%, 10% and 15%. The volume increases in all cases as a linear function of the true tension up to the yield point. As soon as the yield point is reached, the increase of volume is irregular and larger than in the field of elasticity. This additional increase of volume is supposed to be due to internal shearing stresses. GN(6)

The Resistance of Chromium-Plated Plug Gages to Wear. HARRY K. HERSCHMAN. *Bureau of Standards Journal of Research*, Vol. 6, Feb. 1931, pages 295–304.

An investigation of chromium-plated plug gages with particular reference to resistance to wear was made. Chromium was deposited on hardened 1.0% C steel under varying conditions so as to produce what are commonly referred to as "bright," "milky" and "frosty" deposits. The "bright" deposits were tested in both the lapped and unlapped conditions. The other 2 types were tested in the lapped condition only. The scratch hardness values of chromium-plate produced under these varying conditions were studied with a view toward seeking an explanation for the cause of differences in the rate of wear exhibited by the various types of deposits. Metallographic examination of the plate showed the presence of strain lines or cracks on the surfaces of the plated gages. (6)

Comparison of the Results of Different Tests, such as Tensile Strength, Hardness, Elongation, Folding, Bending and Torsion, Relation to Structure, etc. (Verleich der Messergebnisse verschiedener Versuchsarten wie Zugfestigkeit, Härte, Dehnung, Einschnürung, Falt-, Biege-, Verdrehungsziffern, Struktur, Textur, usw.) W. HEROLD (Vienna). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 9–18.

Compares various formulae for prediction of endurance limit and suggests a "tearing strength" figure as showing closest relationship. If R is tearing strength, U is ultimate tensile strength, A is uniform elongation, and B is contraction of area, $R = U(1 + A)[2 - (1 + A)(1 - B)]$. The endurance limit equals 1/4 R. This is said to hold for a variety of carbon and alloy steels. No non-ferrous materials are included in the study. Even for steel, this factor, perhaps averaging 0.25, may vary from 0.22 to 0.27, so that actual endurance tests cannot be replaced by the calculation from the static tension test. HWG(6)

The Hardness Test in Practice. M. MOSER. *Metallurgist*, Dec. 1929, pages 189–190.

A survey of modern methods of hardness testing. The limitations of the Brinell method are set forth and different Brinell testing machines are described. Herbert pendulum hardness, according to the author's opinion, is still divided on its utility and field of application. Translated abstract of an article previously abstracted from *Krupp'sche Monatshefte*, June 1929. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 341. (6)

New Method of Making Ball Hardness Tests of Metals and a Plotting Table for the Simplification of "Meyer (hardness) Analysis." HUGH O'NEILL. *Carnegie Scholarship Memoirs, Iron & Steel Institute*, Vol. 19, 1930, pages 19–38.

8 references. The theory of hardness testing is discussed and the desiderata for a hardness test outlined. The author describes his diamond ball hardness tester. The Meyer analysis involves the determination of two mathematical quantities related as: $L = ad^n$, where L is the load, d the recovered diameter of the indentation, a represents the so-called "unit diameter hardness" and n a "hardenability" or "strain-hardening capacity" factor. The author presents a plotting table for quickly determining the values of a and n graphically. WLC(6)

Photoelasticity and Its Application in Design. R. V. BAUD. *Machine Design*, Vol. 2, Nov. 1930, pages 29–32; Dec. 1930, pages 27–30; Vol. 3, Jan. 1931, pages 37–40, 52.

The first article discusses the choice of methods enabling the designer to judge the safe load of a structure when no service records exist: one is to combine all factors involved in a destruction test; the other to secure stress field information. This second again divides itself into the method of analytical computation of stresses, and the more practical way of making photoelastic tests. The principles are explained, the instruments described, definitions given, and 8 well-selected illustrations contribute to the exposition. The second article covers work done at the mechanics division of the Westinghouse Electric & Mfg. Co.'s research laboratories on gears, bolts, suspension insulators, glassware and locomotive side frames. The third article similarly treats rails; welds; fastening: (a) turbine blades; (b) salient poles; (c) airplane propellers; turbo-elements: (a) coil retaining wedges; (b) teeth and end-plates; commutators. MFB(6)

Deflection of Small Springs Measured Accurately with Novel Tester. F. A. HARSHBERGER. *Electrical Journal*, Vol. 28, Feb. 1931, page 127.

A machine consisting of a simple balance arrangement has a unique provision for testing both the tensile and compressive conditions without change of set up. The tester, which is illustrated is simple in construction and can be made from a few spare parts. The construction is outlined. WHB(6)

The Preparation of Manganese-Free Magnesium. ELSA R. ORENT & O. S. RASK. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2776–2779.

The method consists of an oxidation of the Mn to permanganate form by means of potassium periodate, followed by electrolysis in a specially designed cell in which magnesium hydroxide deposits in a cathode-containing compartment and the permanganate in an anode-containing compartment. An essential feature of the cell is an arrangement whereby hydrogen from the cathode is kept from the permanganate. MEH(7b)

Tests of the Resistance to Repeated Pressure of Forged, Riveted and Welded Boiler Shells. Paper No. FSP-53-6. H. F. MOORE. *Transactions American Society of Mechanical Engineers*, Jan.-Apr., 1931, pages 55–64.

Contributed by the Power Division and presented at the Semi-Annual Meeting, Detroit, June 1930, of American Society of Mechanical Engineers. Data regarding the performance of welded joints in resisting repeated stresses are very important in any consideration of the adoption of welded construction for power boilers, and it is the object of this paper to present such data. Comparative tests were made on (1) a standard A.S.M.E. riveted drum, (2) manganese-steel riveted drum, (3) forged seamless-steel shell, (4) 2 forge-and-hammer welded shells, and (5) 8 fusion-welded (metallic-arc) shells, each drum or shell being subjected to applications of pressure well above the allowable working pressure. The results indicate that under repeated stress properly made welded joints are stronger than the plates themselves when weakened by "stress raisers" such as small holes or surface defects. The tests also give useful data on the strength of drum heads when subjected to intermittent pressures. Paper is followed by interesting discussions sent in by 7 specialists. In "Author's Closure" it is brought out that the number of cycles of stress above the endurance limit which a metal will endure without failure is no reliable criterion of its fatigue strength under millions of cycles of working stress. However, when a boiler shell withstands 100 times the number of cycles of stress it will be called upon to stand in actual service, it would seem to be reasonably safe so far as mere fatigue strength is concerned. MFB(6)

The Calibration of Testing Machines. H. F. MOORE (University of Illinois). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 182–190, 7 figures.

Calibration can be done by direct loading, loading through a lever arm, or by using a test specimen strainometer or proving ring, itself previously calibrated by means of standard weights. Methods of the Bureau of Standards are described. HWG(6)

Relation between Materials Testing and Suitability for Use. Comparison of Results of Various Test Methods. (Zusammenhänge zwischen Materialprüfung und Gebrauchseignung. Vergleich der Ergebnisse verschiedener Prüfungsmethoden.) M. ROS & A. EICHINGER (Materialprüfungsanstalt, Switzerland). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 18–25, 4 references.

Wear tests of rails on the Amsler wear machine are greatly affected by presence of the particles worn off. Wear tests agree well with service results, but choice of rails cannot be made on laboratory tests alone. Broken and unbroken rails showed no appreciable differences in tensile or impact values, but a transverse bending test on the base of the rail showed a difference, deflection being almost 10 times as great in unbroken rails. Endurance properties cannot be predicted from static tests. HWG(6)

Brinell, Rockwell and Scleroscope Hardness of Non-Ferrous Metals. O. SCHWARTZ. *Metallurgia*, Vol. 3, Jan. 1931, pages 109–112.

Translated from *Zeitschrift für Metallkunde*, June 1930. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 909. JLG(6)

Elastic and Inelastic Behavior in Spring Materials. M. F. SAYRE. *Progress Report No. 7 of the A. S. M. E. Special Research Committee on Mechanical Springs* (Technological). Presented at December 1930, Annual Meeting.

Continuation of the fundamental studies begun in *Progress Report No. 5, Trans. A. S. M. E.*, Vol. 52, No. 15, May-August, 1930, paper APM-52-9. The new results were obtained by the use of dead-weight loading instead of a testing machine as in the previous work. Other features were the use of long gage lengths and accurate control of temperature. The aim was a very high order of precision. Report (partial) gives numerous graphs and one summarized table of moduli of elasticity. Among other results, it is shown that energy loss increases sharply with the stress, at a higher power than the square; that non-ferrous materials do not exhibit sharp rise in hysteresis on approaching yield point as in the case of heat-treated steels; that hysteresis loops are unsymmetrical and typically convex upward; and that in successive loops, starting from the same nominal initial load and rising to successively greater peak loads the ascending lines essentially coincide while the descending lines differ for the different loops. See also *Metals & Alloys*, Vol. 1, May 1930, page 524. MFB(6)

Dynamic Phenomena in Fatigue Testing Machines. (Dynamische Erscheinungen in Maschinen zur Prüfung der Schwingungsfestigkeit.) S. SÖRENSEN (Kiev, Russia). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 40–47.

Testing of the Surface Conditions of Sheets. (Zur Prüfung der Oberflächenbeschaffenheit von Blechen.) E. GEROLD. *Stahl und Eisen*, Vol. 51, Jan. 22, 1931, pages 104–106. Report from the Research Department of the United Steel Works, Dortmund.

Various methods have been used to determine the luster of steel sheets. The Kempf-Flügge and the Askania Luster meters were used in these tests and compared with a method developed by the United Steel Works. The last-mentioned method uses a photo-electric cell by means of which the luster can be determined through the inclination of an electric measuring instrument. This new method is suitable for routine shop testing and is preferable to the other methods mentioned above for scientific work. GN(6)

Investigation of Cold-Drawn Bridge Wire. L. S. MOISEIFF. *Proceedings American Society for Testing Materials*, Vol. 30, 1930, Pt. 2, pages 313–349.

Description of tests made on wire for the Ambassador Bridge, over the Detroit River. The tests were carried out by W. A. Slater and B. Stoughton at Lehigh University. Nothing unusual was found. Room temperature creep tests were made at 74,000, 93,000 and 113,000 lbs./in.^{2} Creep at the lower loads was so small as to be of the order of magnitude of errors of observation. At the higher load, the creep up to 2 mo. was 0.00024 in./in.; but all but 0.00001 in./in. of this occurred in the first 2 weeks. The wire was acid open-hearth steel of about 0.80% C. Tensile strength was about 210,000 to 230,000 and proportional limit 90,000 to 120,000 lbs./in.^{2} Kinking and otherwise mishandling the wire had no noticeable effect on the strength. HWG(6)

Second Report on Comparative High-Temperature Tension Tests of Metals at Different Laboratories. H. C. CROSS, *et al.* *Proceedings American Society for Testing Materials*, Vol. 30, 1930, Pt. 1, pages 96–109.

Short-time temperature tensile tests on the same materials, a 0.17% C steel, a stainless steel and a chromium molybdenum steel, made in several different laboratories showed variations in degree of temperature uniformity, and difference in selection of coördinates for plotting results. The maximum deviation from the average was only ±5% in figures for tensile strength, but as much as ±25% for those of proportional limit. Various points in testing technique need to be under better control. The detailed results are given in 5 tables and figures. HWG(6)

Stethoscopic Examination of Welded Products. J. R. Dawson (Union Carbide & Carbon Research Laboratories). *Preprint, American Society for Testing Materials*, Mar. 1931, 5 pages.

Judging the soundness of a weld by the sound produced on tapping it with a hammer is feasible on materials up to 1 1/2" thick. Defects that reduce the strength of a weld by 5 or 10% can be detected, melted out and re-welded. Automatic sound-recording devices to minimize the personal factor are being studied, but aural judgment would ordinarily be relied upon. HWG(6)

Compressive Tests of Jointed H-Section Steel Columns. James H. Edwards, H. L. Whittemore & A. H. Stang. *Bureau of Standards Journal of Research*, Vol. 6, Feb. 1931, pages 305–338.

Jointed steel columns consisting of various combinations of 10 in., 12 in. and 14 in. rolled steel H-sections, were tested in compression. Some of the tests were made with the axes of the columns in line and the others with the outer faces of both upper and lower columns in the same plane. Each combination of H-sections and column arrangement was tested with 5 bearing plates ranging in thickness from 1 to 4 1/4 in. using "low loads" giving an average stress not exceeding 8,500 lbs./in.^{2} in the smaller (upper) column. Tests to failure and repeated load tests were made on a few specimens. Strain-gage readings were taken on 2-in. gage lines on the columns and on 8-in. gage lines on the plates. The deflection of the bearing plates was measured. (6)

Welding Tests. Necessity for Standardization. (Essais des Soudures. Nécessité de standardiser les Essais, Propositions.) H. Dustin (University of Brussels). *First Communication of the New International Association for Testing Materials*, 1930, Group D, pages 48–55.

Brief comment on various methods of testing welded test-pieces. HWG(6)

Wear of Materials under Dry Friction. (Ueber Verschleissbarkeit der Werkstoffe bei trockener Reibung.) M. Füchsel (Berlin Railway Testing Laboratory). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 95–112. Contains bibliography of 275 references on wear and wear testing appearing from 1864 to 1929.

Brief general statement of variables affecting wear, general comment on types of testing machines that have been tried, and an extensive bibliography. Wear testing is still a research method, not suitable for purchase specifications, but will help to show the more suitable types of materials. See also *Metals & Alloys*, Vol. 1, Apr. 1930, page 473. Mathematics of extrapolation in calibration beyond the loads which can be applied as actual weights. HWG(6)

Critical Review of Testing Methods for Welded Seams. (Kritische Betrachtung der Prüfverfahren für Schweissnähte.) H. Kemper. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 5, 1930, pages 65–93.

The author distinguishes between 2 different methods of testing welded seams: the preventative methods, which serve to control the welding work proper and control of the worker, and whereby the test piece is destroyed; and the testing methods, by which the welds made in ordinary routine operation are tested on the finished piece for their quality without destruction of the piece. All of these methods have been subjected to a critical review and the methods of the first class: the tensile strength test, bending test, behavior at high temperatures, hardness test, twisting test, notch-impact and tearing test, fatigue test, metallographic examination are discussed, described and illustrated. To the second class belong judging of quality of welded seam by appearance, electrical test (Sperry test), magnetic tests, acoustic methods, X-ray examination. All methods and apparatus required for it are fully described. 34 references. Ha(6)

Stress Cycles in Gear Teeth. R. V. Baud & E. Hall. *Mechanical Engineering*, Vol. 53, Mar. 1931, pages 207–210.

Previous papers on photoelastic stress analysis at the Westinghouse Research Laboratory may be said to have made history. But the shape of the single-tooth stress curves had not been explained and it was said that "since these curves are of considerable importance, it is contemplated to repeat this experiment with improved test conditions, in which we shall have larger teeth without initial stresses and in which we contemplate using the compensation method and applying only torque of such magnitude that the stresses will be within the proportional limit of the material." These tests have been completed and the paper discusses the results obtained and gives simple rules by which it will be possible to approximate the stress cycles for similar teeth. The paper gives the computation of the actual maximum stress at the fillet of a pinion tooth for various positions of the load, assuming but one tooth in contact at any time. MFB(6)

Flow Characteristics of Some Lead Cable Sheath at Temperatures above Atmospheric. Paper No. FSP-52-32. C. L. Clark & C. Upthegrove. *Transactions American Society of Mechanical Engineers*, Vol. 52, Sept.-Dec. 1930, pages 249–254.

Paper gives results of an investigation with ingenious new apparatus on 3 types of lead cable sheath differing only in the antimony content, which was, respectively, 0.06, 0.6 and 1.2%. At room temperature all 3 compositions elongated at more or less fixed rates with loads as low as 245 lbs./in.^{2} Results would indicate that similar behavior would be obtained with still lower loads and that the behavior of lead at 70° F. should be similar to that of plain C steel at a temperature above its equicohesive range. Increasing Sb content does not result in a decrease in the rate of flow at the lower temperatures, but in a lowered resistance to creep. At 80° to 120° C. higher Sb content results in comparatively high rate of creep. MFB(6)

Static Foundations for Fatigue Fracture. (Statische Grundlagen zum Schwingungsbruch.) W. Kuntze. *Mitteilungen der deutschen Materialprüfungsanstalten, Sonderheft* 14, 1930, pages 17–22; *Zeitschrift Verein deutscher Ingenieure*, Vol. 72, Oct. 20, 1928, pages 1488–1492.

Discussion, in very general terms, of the relationship of factors such as hysteresis, beginning of slip, behavior of notched tensile bars, changes in elastic limit with cold working and other factors determinable by static tests, with fatigue failures. HWG(6)

Experiments to Determine the Friction Coefficients of Lining Materials of Dry-running Automobile Motor Clutches. (Versuche zur Ermittlung des Reibungskoeffizienten von Belagmaterial trockenlaufender Automobilmotorenkupplungen.) Dr. Florig. *Messtechnik*, Vol. 7, Jan. 1931, pages 11–13.

From the Institute of Automotive Vehicles at the Technische Hochschule Dresden. Describes fully a test arrangement for measuring the friction coefficients as function of the pressure between materials, of slip, and of temperature. Results in short are: the friction coefficient of motion reduces somewhat with increasing pressure, the coefficient of rest increases somewhat. With increasing slip the friction coefficient increases for constant temperature, with increasing temperature the coefficient decreases. The coefficient of rest is always lower than the coefficient of motion. The best material is asbestos which is compressed after weaving and ground even. It can stand temperatures up to 350° C. and pressures of 2 kg./cm.^{2}; it has a friction coefficient of 0.3. Asbestos with wire stands the same temperature and has 0.2–0.3 for friction coefficient; but the pressure should be not more than 1 kg./cm.^{2} Ha(6)

Notch Toughness and Static Indices. (Kerbzähigkeit und statische Kennziffern.) W. Kuntze. *Mitteilungen der deutschen Materialprüfungsanstalten, Sonderheft* 14, 1930, pages 27–35; *Archiv für Eisenhuttenwesen*, Vol. 2, Mar. 1929, pages 583–590.

Rather general discussion of the relation of rate of absorbing energy, technical cohesion strength (Trennfestigkeit) obtained by extrapolation from tensile tests on notched bars, elongation, reduction of area, changes during stretching and drawing, ability to stand deformation, etc., etc., with notch toughness. A material may be very ductile in static tension, with high elongation and reduction of area, and yet be notch-brittle. A high ratio of "technical cohesion strength" to tensile strength in an alloy that has not been deformed, means high notch toughness. HWG(6)

Notched-Bar Tests. E. Hoeg (Danish State Testing Institute). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 213–216.

Overheating a 0.15% C open-hearth steel at 1100° C. followed by air cooling caused its impact resistance to drop (key-hole notch, square Charpy bar), but on then air-cooling from 900°, the impact resistance was restored. The impact figures are, in kgm./cm.^{2}, original, 18.3; 1100° C. — 1 hr. air cool 10.3; 1100° C. — 2 hrs. air cool 7.6; 1100° C. — 3 hrs. air cool 3.3; 1100° C. — 3 hrs. air cool, 700° C. — 1/2 hr. air cool 4.5; 1100° C. — 3 hrs. air cool, 900° C. 1/2 hr. air cool, 16.2. Specimens from a boiler that had exploded were tested at various temperatures. Average longitudinal and transverse impact was in kgm./cm.^{2} — 20° C, 0.9; +1° C., 3.3; +15° C., 7.0; +250° C., 7.8; +500° C., 3.3; after annealing at 700° C., the figures were +15° C., 10.2; and after annealing at 850° C., +15° C., 8.7; +500° C., 3.1. That is, at 500° C., the rejuvenation brought about by the 850° C. treatment, is lost. HWG(6)

Wearing Tests on Iron and Steel. (Om nötningsprov a järn och stal.) Arvid Johansson. *Jernkontorets Annaler*, Vol. 114, Nov. 1930, pages 551–571.

Lectures delivered at Tekniska Högskolan during 1928. A critical discussion of various tests for wearing resistance including Robin's, Brinell's, Spindel's and Amsler's. The general conclusions are that wearing resistance increases with increased C content, with increased coarseness of structure and with increased speed of rotation. The general status of the results is, however, highly uncertain. Problems for further research are: The effect of crystal structure as determined by the chemical analysis, the heat treatment, the final working temperature and the slag inclusions. 7 references. HCD(6)

Tests on Electric Arc Welded Lap Joints. R. P. Davis & L. V. Carpenter. *Research Bulletin* No. 7, Eng. Expt. Station, W. Va. University, Series 16, No. 2, Nov. 1930, 16 pages.

Tests of a few lap welds, some longitudinal, some end welds with 1/4 or 1/2" weld fillet, and varying length of weld. Striking the specimens with a hammer after welding and listening to the "ring" did not give any correlation with the tensile test. Long welds were weaker per lineal inch than short ones, and the unit strength of a 1/2" weld fillet is less than that of a 1/4" fillet. HWG(6)

Tensile Strength of Threaded Rods. R. P. Davis & L. V. Carpenter. *Research Bulletin* No. 6, Eng. Expt. Station, W. Va. University, Series 16, No. 1, July 1930, 12 pages.

Structural steel rods from the stock room, composition and structure not stated, were tested unmachined, and turned to a smaller diameter. A 5% increase in unit tensile strength on the turned rods is ascribed to "cold working." The tensile strength of threaded rods based on area at root of threads is 15% greater than plain, unmachined rods, but if the stress was applied by turning down the nut, the strength was less than with the plain rods. HWG(6)

Relation between Deformation in Tensile and Bending Tests. (Zusammenhang zwischen den Deformationserscheinungen in der Zug-, und Biegeprobe.) J. Bartel (Budapest). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 31–36.

Fracture in a bend test starts from the middle rather than from the edge of the specimen, because the middle is undergoing the greatest change in area. The change depends on thickness of bar and radius of bend. HWG(6)

The Deformation of Metals Under Prolonged Loading. Part I. The Flow and Fracture of Aluminum. D. Hanson & M. A. Wheeler (The University, Birmingham). *Institute of Metals, Advance Copy* No. 554, 1931, 29 pages.

Al samples were subjected to static loads at room temperatures and at 250° C. The mode of deformation was determined by microscopic examination of the polished and unetched surface of the test specimens. Samples consisting of various sized crystals, including single crystals were used. The conclusions, as given in the synopsis are: "(1) The extension under a prolonged load that will ultimately break the metal may be conveniently considered as consisting of 3 periods: (a) a period of primary extension, during which the rate of flow diminishes; (b) a period during which the flow is very slow or even suspended; (c) a period during which the extension again continuously increases until fracture occurs. (2) During the first period the flow of the metal is the result of slip within the crystals, and flow diminishes owing to the hardening effect of slip. (3) The behavior during the second and third periods varies with different specimens. (4) Three types of failure have been recognized under creep conditions: (a) failure by intercrystalline cracking; cracks form while the elongation is low, and the metal fails with little reduction of area at the fracture; (b) failure by the resumption of slipping within the original crystals, leading to a fracture of the normal type; (c) failure through the recrystallization of the metal, removing strain-hardening and permitting further flow of the softened metal: the metal pulls out to a point fracture, with a high elongation. (5) Al can fail by "creep" at room temperature. (6) Al consisting of uniform aggregates of crystals fails at 250° C. by intercrystalline cracking. (7) Al aggregates at room temperature, and Al single crystal specimens at all temperatures, fail under creep conditions by shear along the slip planes. (8) In single crystals when flow recommences slip occurs only on some of the surfaces that had previously slipped during the primary flow. (9) The prolonged action of a suitable stress can cause disintegration of a metal either at the junctions of the grains or on the surfaces of previous slip, and failure (i. e. fracture) must be regarded as having commenced when this weakening occurs. (10) Under suitable conditions, e. g. in crystal aggregates with moderate rates of flow at 250° C., or with very slow rates of flow in single crystals, slip is distributed over a very large number of slip surfaces, and a polished surface of the metal may show little or no signs of slip bands. (11) No change in density is believed to occur when a crystal is distorted by moderate amounts: changes in density in the case of crystal aggregates are thought to occur at grain boundaries. (12) The view is expressed that rupture of the crystals commences along slip planes formed at an early stage in the deformation of the metal. (13) The results are consistent with the theory of slip and rupture previously advanced by Gough, Hanson and Wright." Contains 4 references. JLG(6)

Ideal and Practical Relations between Elasticity and Plasticity, Tenacity and Brittleness. (Begriffliche und prüfmethodische Beziehung zwischen Elastizität und Plastizität, Zähigkeit und Sprödigkeit.) P. Ludwik (Vienna). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 63–71, 18 references.

Discussion of type of failure in tension, shear and repeated stress. Three-dimensional stresses are considered. HWG(6)

Comparison of the Results of Different Tests, such as Tensile Strength, Hardness, Elongation, Contraction, Folding, Bending, Torsion, Fatigue, Notched-Bar, etc. (Vergleich der Messergebnisse verschiedener Versuchsarten wie Zugfestigkeit, Härte, Dehnung, Einschnürung, Falt-, Biege-, Verdrehungsziffern, Schwingungsfestigkeit, Kerbschlagprobe, usw.) W. KUNTZE (Berlin, Materialprufüngsamt). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 1–8, 5 references.

Advocates use of an extrapolated value "Trennfestigkeit," (Technical Cohesion Strength), obtained by tensile test on notched bars (60° notch) and plotting the results so as to extrapolate to zero cross-section (complete notching), or by the formula $T = U + F/f\ (N - U)$ where T is Trennfestigkeit, U is ultimate strength by tensile test on an un-notched bar, F is the area of the notched tensile bar breaking section before notching, f the area at the root of the notch, and N is the strength per unit area of the notched bar. The figure T represents the strength when local deformation is entirely inhibited. It is a true material constant. Ability to resist flow increases with T. A yield point value is not a true material constant, but depends on speed, form and temperature. The maximum uniform elongation before necking starts and the local contraction thereafter have 2 different meanings in relation to resistance to flow. The latter is related to notch-toughness, more directly than is the total work to fracture in tension. Endurance limit may be calculated by a formula involving the ultimate tensile strength, an exponent (which is slightly different for tension, compression and for repeated bending endurance tests), the stresses at the end and at the beginning of the uniform necking-down period. Tensile tests in which load, at beginning and end of uniform elongation, maximum load, load at fracture, and the uniform elongation and local contraction at each stage are noted, together with the notch tensile test and notched bar impact tests, should throw light on the danger and the cause of fracture. HWG(6)

Materials for and Wear of Plowshares. (Werkstoffe und abnutzung von Pflugscharen.) K. GALLWITZ (Doktor-Ingenieur dissertation, Tech. Hochschule, Berlin), June 1929. Published by G. Zichaus Dessau, 1930. 50 pages.

Several year's work was put upon a field study of the wear of plowshares, in which the relative wear of the share was compared with the wear upon a standard soft steel (130 Brinell) specimen fastened to the coulter of the plow. This comparison took care of differences in the nature of the soil plowed. If the soil were first harrowed and rolled, the wear results were more consistent. Laboratory tests were made by running 3 shares, mounted on a revolving frame, turned by a 30 kw. motor, in sand, held in a ring-shaped cement canal. The shares moved at 3 m./sec. The cross-section of the ring of sand had a breadth of about 80 cm., and a height of about 40 cm. Building sand of a range of grain sizes from 1 to 1/4 mm. (mostly 1/2 mm.) was used, and maintained at 10% moisture. Weight losses in individual tests on full-sized shares were 5 to 30 g. in the laboratory per 10 km. run, and 30 to 600 g. in the field tests per 3 km. run. Many precautions as to angle of setting of the shares, running only shares of the same size together in the laboratory test so that a big one will not throw some of the sand out of the way of the following one, etc. were worked out. In any set of tests, the comparative rates of wear in g./cm.^{2} in the laboratory and in the field tests (after correcting the latter for nature of the soil by means of the control specimen) agreed very well, indicating that the laboratory method gave true results.

All the shares had hardened edges, but were soft at the bolt-holes except one 1.2% C, 10.7% Mn steel, and a few unhardened carbon steels put in for comparison. The wear was in quite direct proportion to the unhardened area. Quite a range of steels were used, most of them 0.50 to 0.70% C, several with Mn from 0.80 to 1%. One that showed up well contained 0.45% C, 1.8% Mn. The austenitic 10.7% Mn, 1.2% C steel of 193 Brinell showed as good results.

Poor results were obtained with shares whose edges showed Brinell hardnesses over 600, these having been over-heated, and showing Widmanstätten structure. Such shares often have quenching cracks.

The edge of the share should be between 400 and 550 Brinell, and as much of the share should be of that hardness as possible, as long as the zone about the bolt-holes is tough. Only in especially strong ground is it necessary to sacrifice hardness of the edge and body of the share for toughness. The investigation did not lead to any conclusion as to a choice among different steels that will give the desired hardness.—H. W. Gillett (6)-B-

Fatigue of Single Crystals of Pure Metals. H. J. GOUGH (National Physical Laboratory, England). *First Communications of the New International Association for Testing of Materials*, Group A, Zurich, 1930, pages 134–144, 11 references.

Discussion of mode of deformation of, and propagation of, cracks under repeated stress, in single crystals of aluminum, α-iron and zinc. The direction of slip is parallel to the line of atoms in the lattice, having the most atoms per unit distance. Direction of propagation of cracks is often determined by maximum shear stress. Some theoretical discussion is given. HWG(6)

Meaning of the Notched-Bar Impact Test for Investigation and for Acceptance Test Purposes. R. H. GREAVES (Woolwich Arsenal, England). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 225–230.

Discussion of the transition zone from high to low impact figures. High figures accompany shear failure, with deformation, low ones, three-dimensional tensile stress with little deformation. The transition is affected by dimensions of test piece, form of notch, rate of loading and temperature of test. Moser's method of using specimens of 2 different breadths, does not simplify the test, but shows that change in breadth can reverse the indications of the test. The usual impact test is a better indicator in alloy than in carbon steels, the transition region with carbon steels being close to the usual conditions of test. However, a bad impact figure always indicates liability to failure under local stress. Experience shows that material that fails by cracking or fracture in service, gives poorer results in notched bar tests than material that does not fail in service. HWG(6)

Stress Analysis by Strain Gages. T. W. GREENE. *Product Engineering*, Vol. 2, Jan. 1931, pages 11–13.

Use of strain gages is described, and interpretation of resulting data for analyzing stress distributions in old and new designs set forth. Typical examples given. MFB(6)

The Safety of Rotors of High-Speed Turbo-Generators of Large Output. R. W. BAILEY & G. A. JUHLIN. *Engineering*, Vol. 130, Aug. 22, 1930, pages 242–244.

Gives details of hair crack defects and their detection in rotor forgings. Body of forging should be made longer than necessary at the end corresponding to the top of the ingot. When excess material has been removed, enough of segregate zone will be exposed to serve for adequate examination. Testing process consists in magnetizing forging, gently washing surface with stream of paraffin carrying chemically prepared, extremely finely-divided iron powder. Fine cracks are made visible by adherence of iron particles, bridging cracks under the magnetic field existing across them. Alloy steels of Ni, Ni-Cr and Ni-Cr-Mo types are liable to develop hair cracks. To produce reliable forgings attention should be given to composition, proper heat treatment and effective inspection methods. LFM(6)

Torsional-Vibration Dampers. (Annual Meeting Paper.) J. G. BAKER & J. P. DEN HARTOG. *S. A. E. Journal*, Vol. 28, Feb. 1931, pages 184–190.

In internal-combustion engines operating over a wide speed-range, critical speeds of torsional vibration cannot practically be avoided. The ensuing vibrations, if not checked, set up high alternating stresses in the shaft which have in numerous cases led to fatigue failures, many of these occurring in the crankshaft. Several devices that successfully limit these stresses to safe values during any critical speed have been developed. The fundamentals of torsional vibration and these stress-limiting devices are discussed. According to authors, stresses set up during a critical speed can be calculated in advance. Tests made on a model in the laboratory are described and the results thus obtained prove the methods of calculation to be reliable. MFB(6)

The Strength and Testing of Materials. *Metallurgist*, Sept. 27, 1929, pages 133–135.

An extensive review of Report No. 13 of the Swiss Association for Testing Materials written by P. Ludwik. See "Fatigue Tests with Construction Materials," *Metals & Alloys*, Vol. 1, Dec. 1930, page 909. (6)

Behavior of Oxy-Acetylene Cut Material under Endurance Impact Tests. (Ueber das Verhalten von autogen geschnittenem Material bei dauernder Beanspruchung durch Schlag.) L. v. ROESSLER. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 5, 1930, pages 54–61.

Review of tests made to determine, by impact tests, the differences between machined material and material cut with oxygen, with the former taken as standard. Methods, apparatus and micrographs are given; a definite conclusion as to the better behavior under these tests could not, however, be drawn, in spite of the large number of tests made. Ha(6)

Temperature Effect. Compression and Extrusion. A. PORTEVIN. *Metallurgist*, Nov. 1929, pages 173–175.

A review of a paper previously abstracted from the *Revue de Mètallurgie*, Aug. 1929. The relationship between the behavior of a given metal or alloy under high-temperature compression test and its behavior in the extrusion press is discussed. The author obtains autographic stress-strain diagrams of 4 distinct types and an interpretation of these 4 types in terms of a single generalized pair of curves representing deformation of metal under viscous flow and under work-hardening conditions, respectively. See *Metals & Alloys*, Vol. 1, Jan. 1930, page 341. (6)

Why the Block Test for Drill Steel? OCHA POTTER. *Engineering & Mining Journal*, Vol. 129, May 23, 1930, pages 506–508.

The "block" test consists of putting a piece of steel of specified length and diameter in a rock drill with a bit about 1/4 inch from a steel anvil block and running the drill under certain standard conditions until the steel fails. The origin, development and procedure of the test method show the value of this "shop" test. Twelve details are listed of the application of the test at the Calumet and Hecla Ahmeek-Kearsage plant. WHB(6)

Further Experiments on the Magnetostriction of Over-strained Materials. J. S. RANKIN. *Journal Royal Technical College*, Glasgow, Vol. 2, Jan. 1931, pages 385–395.

Experiments are discussed and curves of results plotted for nickel rods, mild steel rods and iron wire. The magnetostrictive phenomena are tentatively ascribed to elastic internal stresses. HWG(6)

The Lubricating Properties of Mineral, Vegetable and Fatty Oils. A. S. T. THOMPSON & P. S. CALDWELL. *Journal Royal Technical College*, Glasgow, Vol. 2, Jan. 1931, pages 490–502.

While this deals with oils rather than bearings, some friction tests are tabulated for the same oils (a mineral oil, rape, castor and sperm oils) on bearing surfaces between mild steel and cast iron, mild steel and leaded bronze and cast-iron and cast-iron. With complete fluid lubrication, the nature of the bearing surfaces did not materially affect the coefficient of friction shown by the various oils. HWG(6)

Mechanical Wear. (Mechanische Abnützung.) M. SPINDEL (Railway Testing Lab., Vienna). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 113–118.

Wear resistance depends on the conditions of service, hence, tests made under different laboratory conditions will not agree. A graph is shown for laboratory tests, the conditions of which are not clearly stated. An intermediate Mn rail shows the best results next to 2 "wear resistant electric steel rails of special composition," the composition not being stated. The service results on these rails appear to agree fairly well with the laboratory tests. HWG(6)

Research on Wear Testing. (Ueber die Prüfung der mechanischen Abnützung.) DANISH STAATSPRÜFUNGSANSTALT (Copenhagen). *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 81–85.

Refers only to wear testing of cement, leather, cork, linoleum, etc. In one method, fresh sandpaper or emery paper is drawn under the specimen by mechanical means. HWG(6)

The Propagation of Large Barkausen Discontinuities along Wires. K. J. SIXTUS & L. TONKS. *Physical Review*, Vol. 35, June 1, 1930, page 1441.

Abstract of paper presented at the Apr. 26, 1930 meeting of the American Physical Society, Washington, D. C. Preisach has shown that by applying increasing tension or torsion to a wire of Ni-Fe alloy, the Barkhausen discontinuities in magnetization become larger and larger. At a tension near the elastic limit, a rectangular hysteresis loop is produced whose discontinuous change in magnetization includes 97% of the whole difference between positive and negative saturation. Langmuir suggested that this sudden change in magnetization starts at a nucleus from which it propagates along the wire. Investigation based on this view shows that the nucleus forms in a uniform field at a somewhat variable critical field strength and at different points along the wire depending, apparently, on uncontrolled factors. The nucleus can be made to form at a definite point, however, by applying locally a small additive field, and the discontinuity will then propagate into the uniform portion of the field, the strength of which can be smaller than the critical field strength. The velocity of propagation increases for a given sample with increasing field strength and tension. A 10% Ni-90% Fe wire of 0.038 cm. diameter showed velocities from 2000 to 14000 cm. sec.$^{-1}$ (6)

Determination of the Creep Limit According to the Short Time Test. (Zur Bestimmung der Dauerstandfestigkeit im Abkürzungsverfahren.) A. POMP & W. ENDERS. *Stahl und Eisen*, Vol. 5, Feb. 5, 1931, pages 157–162; *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, Report 152, pages 127–147.

Continuation of previous investigations by A. Pomp & A. Dahmen (*Mitteilungen Kaiser Wilhelm Institute für Eisenforschung*, Vol. 9, 1927, pages 33–52; *Stahl und Eisen*, Vol. 47, 1927, pages 414–415) on the determination of the creep limit by an abbreviated method, the present investigation studied the suitability of this method which has been improved in the meantime. In this method the extension is optically measured and recorded while the specimens are subjected to a load. The accuracy of these extension measurements could be essentially increased. Four straight carbon steels (C:0.06–0.61) 3 types of cast steel containing Cu and Ni and a 13.44% Cr steel were tested at 300°, 400° and 500° C. respectively. The results of the tests which in part have been extended over 240 hrs. indicate that a higher velocity of extension than 0.0003%/hr. can be applied between the 3rd and 6th hr. In alteration of Pomp and Dahmen's previous suggestions the creep limit of straight carbon steels is defined as that maximum load at which the velocity of extension does not exceed 0.0003% between the 5th and 10th hr. INDUSTRIAL USES & APPLICATIONS (9)

Metal Airplane Construction. FRANK M. SMITH. *S. A. E. Journal*, Vol. 28, Mar. 1931, pages 387, 392.
Recent practice in Duralumin construction described and low jig-cost revealed. (9)

The Use of Antimonial Lead for Accumulator Grids: A Cause of Self-discharge of the Negative Plates. J. T. CRENNELL & A. G. MILLIGAN. *Transactions Faraday Society*, Vol. 27, Mar. 1931, pages 103–112.
As the life of Pb storage batteries increased, it was more difficult to maintain the capacity of the negative plate owing to sulphation. The changes that occurred in the behavior of the negative plate are: (1) the rate of gas evolution, measured on open circuit, increased during the life of the cell; (2) the polarization when gassing on charge, decreased; (3) current efficiency was reduced. These changes affect the efficiency and capacity of cell and are due to lowering of overvoltage for H evolution, brought about by the deposition upon the negative grid, of Sb from the positive Sb-Pb grid. Rate of removal of Sb from positive grids is higher when the grids are older. Charging cell in opposite direction and then changing the electrolyte only brings about temporary improvement. Sb-Pb should not be used for positive grids of Pb storage batteries. PRK(9)

Blades of Rustless Steel. (Klingen aus nichtrostendem Stahl.) FRANZ BAHNER AG. *Deutsche Goldschmiede Zeitung*, Vol. 34, Feb. 21, 1931, page 4.
Rustless steel as now made makes excellent knife blades. Its general use in place of silver plated blades is predicted. JLG(9)

Wire Rope of Stainless Steel. *Power*, Vol. 73, Mar. 17, 1931, page 459.
In addition to resisting chemicals, salt water and salt air corrosion, the wire rope of chrome nickel alloy steel now being put out by the Hazard Wire Rope Co., Wilkes-Barre, Pa. under the name of "Korodless" can, it is claimed, be safely operated in temperatures up to 1650° F. As in other types of wire rope manufactured by the company, performed construction is used, the strands and wires being helically shaped to the exact form they assume in the rope structure. This construction, it is claimed, eliminates internal stress and allows the individual wires to lie side by side without undue internal friction, thus materially increasing the life of the rope. Standard sizes are available. VVK(9)

Aluminum Alloy Used in Enginehouse Doors. *Railway Age*, Vol. 90, Feb. 14, 1931, page 376.
The Norfolk & Western has recently installed 21 vertical rolling or curtain-type doors of aluminum alloy in one of its enginehouses at Williamson, W. Va. The doors are 13 ft. wide by 19 ft. 11 in. high and weigh 323 lbs. each. The slats of the doors are made from 19-gage aluminum alloy sheet and the bottom bar in each case is an angle section of the same material produced by the extrusion process. The weight is 1/3 that of similar galvanized sheet steel doors. Because of their corrosion resistance, it was not considered necessary to paint them. VVK(9)

Alloys Steels in the Railroad Field. CHARLES MCKNIGHT. *Transactions American Society Mechanical Engineers, Railroads*, Vol. 52, Sept.-Dec. 1930, pages 81–93.
There is an increasing interest in the use of alloy steels for railroads. They are used purely as a matter of economics. Better work must be done at the same cost or the same work at less cost. The use of alloy miscellaneous castings materially cuts down weight with the same strength and same cost as carbon steel castings. There are 3 ranges of steels: Carbon steels are used for special applications and semi-alloy steels, which are slightly more expensive than carbon steels and with slightly better properties as a compromise. Some of the uses include boiler materials, forgings and castings. Corrosion resisting materials, nitriding and miscellaneous materials are discussed and the economies of each are given. (9)

Some Aspects of the Uses of Fabricated Aluminium in the Chemical Industry. S. JAMIESON RALPH. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 459–464.
A review covering aluminum and its alloys. MPB(9)

Aluminum Street Cars Save One Fifth the Weight. A. M. ROBINSON. *Metal Progress*, Vol. 1, Oct. 1930, pages 53–57.
The increasing tendency to use aluminum for structural parts as well as for fittings and body sheathing results in a saving in weight of 20% and higher with attendant operating economies. WHK(9)

All Metal Sectional Houses in Use in Germany. *Metal Industry*, New York, Vol. 29, Mar. 1931, page 122.
A recent development is sectional houses of all metal construction with copper exteriors and finished sheet metal interiors. PRK(9)

The Making of Mirrors by the Deposition of Metal on Glass. *Bureau of Standards Circular* No. 389, 1931, 17 pages.
This publication supercedes Letter Circular No. 32 and deals principally with the methods for producing mirrors by the chemical decomposition of Ag on glass. The Brashear, Rochelle salt and formaldehyde formulas are given, also a detailed discussion of the precautions necessary to avoid danger, and the technique necessary to obtain the most satisfactory results. Reflecting films are produced on glass by the chemical decomposition of Cu, Pt or Pb sulphide by cathode sputtering, and by condensation of vaporized metals. WHB(9)

The Design and Manufacture of Special Steel Castings for Rolling Stock. *Canadian Foundryman*, Vol. 22, Mar. 1931, pages 10–12.
Part II of a paper presented by H. R. Bartlett before the Canadian Railway Club, of Montreal, which deals with the design and manufacture of castings for locomotives and trailer trucks. Reference is made to the largest and heaviest cast steel bed which has so far been manufactured, and which incorporated a 3-cylinder arrangement with the center cylinder on an angle. The casting weighed 82,000 pounds and was 60 ft. 4 in. long. The molding methods used in the preparation of the steel castings referred to are dealt with briefly. OWE(9)

Increasing Use of Silver in Chemical Industry. *Canadian Mining Journal*, Vol. 52, Mar. 20, 1931, pages 304, 312.
An abstract of a paper by Donald McDonald read before the Society of Chemical Industry at London. Resistance to corrosion and lowered cost have stimulated interest in Ag for use in the chemical industry. Resistance to organic acids and the use of Cu-Ag alloys and Cu with Ag rolled on for reduction of first cost of the apparatus. For the melting and casting of caustic alkalies Ag is widely used. For its use in the Drumm storage battery (alkaline electric accumulator) much higher rates of charge and discharge and a much greater capacity per unit of weight are claimed. Ag is being investigated in locomotive traction. WHB(9)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

High-pressure and Low-pressure Acetylene for Welding. (Hochdruck- und Niederdruck-Azetylen im Schweissbetriebe.) Report of the Laboratory of I. G. Farbenindustrie, Frankfurt-Main. E. ZORN. *Autogene Metallbearbeitung*, Vol. 24, Jan. 15, 1931, pages 20–25; Feb. 1, pages 35–43.
Exhaustive tests to solve the problem of the most favorable pressure of acetylene in welding with regard to the kind of burner, injector burner for low pressure, uni-pressure burner for high pressure, and also with regard to the necessary equipment, flame, capacity of welding, quality of weld, lead to the following conclusions: high pressure acetylene and the use of uni-pressure burner is better because the losses in the hose are negligible and the flame is much steadier; for the low-pressure injector burner the length of hose is of considerable influence because for long hose the oxygen is mostly in excess in order to get the necessary acetylene to the burner by the injector effect. A neutral flame with an escape velocity of about 130 m./sec. is about the most favorable condition. This most favorable condition can best be regulated and maintained with the injectorless uni-pressure burner; this burner does not require constant regulating after the first adjustment. For this reason, the acetylene under pressure has found greatest application in modern oxy-acetylene welding plants. Ha(11c)

Welding Aluminum Crank Case. T. SAKAMOTO. *Welding*, Vol. 2, Mar. 1931, page 179.
On account of the widely varying sections in the complicated casting, the whole piece was pre-heated before the welding torch was applied in order to avoid interior stresses by unequal heating. Ha(11c)

Two Interesting Welding Jobs Made in Hawaii. T. SAKAMOTO. *Welding*, Vol. 2, Jan. 1931, page 21.
Short description of work in a sugar mill. Ha(11c)

Recent Application of Welding for Heating Plants. (Neuzeitliche Anwendung der Schweisstechnik bei der Installation von Heizungsanlagen.) HELLMUT SCHEEL. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 61–63.
Description of distribution pipe lines in basements, hot-houses, industrial plants and residences which can be made economically by welding. Ha(11c)

Welding Insures Strength and Beauty. J. A. SCHAEFER. *Welding*, Vol. 2, Mar. 1931, pages 185–187.
The Dreix & Krump Co. make all their master tools used in sheet work of welded steel. Ha(11c)

Welding of Heating Pipe Lines. (Schweissungen von Fernheizleitungen.) HERM. RICHTER. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 55–57.
Description of welding for central heating plants with long pipe lines. Ha(11c)

Atomic Hydrogen Welding. C. I. MACGUFFIE. *Baltimore Engineer*, Vol. 5, Aug. 1930, pages 15–16.
General notes on development process and equipment. (11c)

A Modern Method of Training Welders. W. D. PATTERSON. *Welding*, Vol. 2, Jan. 1931, pages 15–17.
The course of the American School of Welding, Inc., St. Louis, Mo., requires 245 hours. Short description of the course which comprises both electric and oxy-acetylene welding. Ha(11c)

Facts Concerning Welding of Rail Ends. S. E. TRACY. *Welding*, Vol. 2, Feb. 1931, pages 114–118.
Building up battered rail ends is of extreme importance in the maintenance of railroad tracks from the point of view of safety and economy. The Chicago, Burlington & Quincy Railroad has used welded rail joints extensively. The principal methods are described and hardness tests are given. The cost per joint was $2.0144 for electrically welded ends, while only $0.81 for welds with oxy-acetylene; the difference is due mainly to the costlier equipment and greater amount of labor required. Ha(11c)

Design of Welded Crane Columns. C. M. TAYLOR. *Welding*, Vol. 2, Feb. 1931, pages 107–109.
Some simplified structural details are described which make a strong and rigid construction economical to erect. Ha(11c)

Welding Technique and Heating Industry. (Die Schweisstechnik und das Heizungsgewerbe.) P. THELEN. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, page 52.
Remarks on progress made in the manufacture of tanks, boilers and radiators for heating purposes by welding. Ha(11c)

Stress Relieving Improves Welded Machine Parts. G. D. SPACKMAN (Lukenweld, Inc.). *Steel*, Vol. 87, Nov. 20, 1930, pages 62–63.
The cases in which residual stress is so objectionable that it is necessary to stress relieve the whole structure in a furnace are: (1) residual stress which results in unit loads possibly twice as great as the loads for which the stressed member was designed; (2) residual stress which causes warping beyond permissible limits; and (3) residual stress which results in warping of the piece beyond permissible limits during machining operations. In general, appreciable residual stress is left in a welded joint when there is more weld metal on one side of the center than on the other. MS(11c)

Gas Welding and Cutting for Garage Profits. *Welding*, Vol. 2, Apr. 1931, pages 243–245.
If a garage is equipped with welding outfits, profits can be increased by taking in outside work of crankcase and cylinder block repairs, building of trailers, fenders, etc. Ha(11c)

The Bronze Welding of Cast Iron Pipe. *Welding*, Vol. 2, Apr. 1931, pages 235–237, 241.
The advantage of this method is pointed out and illustrated with two recently completed water pipe lines. Instructions are given for carrying out this technique correctly. Ha(11c)

Two Portable Arc-Welders. *Welding*, Vol. 2, Mar. 1931, pages 192–193.
Dynamo of 300-amp. continuous capacity mounted on Ford truck and driven by its engine, built by the Shrader Elec. Co., Los Angles, Cal. Ha(11c)

Bed of Pipe Machine Assembled by Welding. *Welding*, Vol. 2, Mar. 1931, pages 190–191.
Special machine of the Moline Tool Co. for boring, hollow milling and threading of long sections of pipe. Total weight, 6000 lbs. Ha(11c)

Templet for Fabricating Bends in Large Pipes. *Welding*, Vol. 2, Jan. 1931, pages 43–44.
Description of a method useful in the field. Ha(11c)

Testing Sheet Steel for Weldability. *Welding*, Vol. 2, Jan. 1931, page 43.
To find whether a particular piece of sheet is suitable for oxy-acetylene welding, the following test is recommended: a piece about 6-in. square is blown with a neutral flame to melting for about 3-in. length and a hole burnt. If the quality is good, no excess of oxide or scale will be noticeable and the upper side will be smooth. Ha(11c)

New San Diego Water Line is Arc-Welded. *Welding*, Vol. 2, Jan. 1931, pages 42–43.
About 86,000 ft. of 40" and 36" pipe over and through hills, of a wall thickness of 1/4" to 3/16." Ha(11c)

Fundamentals of Resistance Welding. TH. D. KETCHBAW. *Welding*, Vol. 2, Jan. 1931, pages 40–41.

General remarks on current used, machine construction, function of transformer and preparation of the work. Ha(11c)

Acetylene Welder's Manual. (Leitfaden für Acetylenschweisser.) THEO. KAUTNY. Carl Marhold Verlagsbuchhandlung, Halle a. d. S., 1930. Cloth, 5 × 7 inches, 256 pages. Price 5.20 RM.

This compact little manual brings, in a very condensed but yet sufficiently clear and correct manner, everything that a practical man needs for the understanding of the nature of welding processes, preparation of the material, selection of methods and materials; in short, everything pertaining to this art—but nothing that is not just as well treated in American handbooks. Worthy of recommendation is the chapter on the welding of nonferrous materials, which is very complete and, also, deals with some metals, not essentially of industrial use.—M. Hartenheim (11c)-B-

Practical Acetylene Welding Manual. (Manuel Pratique de Soudure Autogene.) R. GRANJON & P. ROSEMBERG. Dunod, Paris, 1929. Paper, $5^1/_2 \times 8^1/_2$ in., 410 pages. Price 31.60 Fr.

For this manual, the very same remarks could be made as for the foregoing German manual. Beside the same matter, it contains a few more calculations and a few more drawings to show the preparation, step by step, of the pieces to be welded. A large amount of space, not without reason, has been devoted to the execution of repair work. It is one more complete treatise of this art, of which there are already so many on the market. This is, however, by no means meant as derogatory to its value for French welders.—M. Hartenheim (11c)-B-

Practical Oxy-Acetylene Welding. R. GRANJON, P. ROSEMBERG & A. DESGRANGES. *The Welding Journal*, London, 1929. Paper, $5 \times 7^1/_4$ inches, 181 pages. Price 3/6 sh.

Translated from the French. It is very questionable if there was, in view of the lately rising flood of publications on welding in the home market, an urgent necessity for the translation of a French manual. This is even more true, since this manual contains quite a few examples of American practice and quotations from American literature. Its completeness, in every respect, cannot be denied, although the arrangement of material in the original seems preferable to that in the translation.—M. Hartenheim (11c)-B-

The "Carolinian," an All-Welded Ship. ELLIOT HARRINGTON & O. A. TILTON. *Welding*, Vol. 2, Jan. 1931, pages 18–20.

Short description with illustrations of the methods used which, it is claimed, saved 20% in weight and 25% in cost. The ship is an oil-tanker 120 ft. long and 23 ft. beam. Ha(11c)

Detection and Fixation of Tension-Fissures in Welds. (Auffindung und Darstellung von Spannungsrissen an Schweissungen.) H. KEMPER. *Autogene Metallbearbeitung*, Vol. 24, Feb. 15, 1931, pages 57–60.

Two methods are described which permit the detection and recording of the finest cracks in welds: (1) The penetration method, using light oils to make the cracks visible. It can be applied without smoothing the seam over. A thin oil is brushed on the weld and left there for a while so that it penetrates into the fine fissures by capillary action. The superfluous oil is wiped off and a solution of calcium carbonate (chalk) in alcohol is brushed on. As the alcohol evaporates quickly, a coating of chalk remains which absorbs some of the oil in the cracks and thus clearly shows the size and location of cracks. (2) The sulphur-print method. Here, the crush of the weld seam must be removed. The weld is covered with a dilute sulphide solution which penetrates into the fine cracks. After cleaning thoroughly, a piece of paper sensitized with silver bromide and dipped in a 5% solution of H_2SO_4 is pressed onto the place for about a minute after which the sulphide solution in the cracks blackens the paper which shows the cracks as fine lines. These prints can be developed and fixed in the usual manner. These methods have been used in the laboratory of Chemische Reichsanstalt. Ha(11c)

Construction of Welded Girders. (Ausbildung geschweisster Blechträger.) H. GOTTFELDT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Dec. 27, 1930, pages 1755–1757.

The characteristic difference between a riveted and a welded girder plate consists in that, for the latter, no angle irons are required for joining the flange plates to the web. Based on this difference, the different possibilities of forming the sections are thoroughly treated, namely the arrangement of several plates one upon the other or plates of different thicknesses butted together. The order of the welds and the most suitable gradation of the section of the reinforcing plates are discussed and the various forms critically treated. Ha(11c)

Method of Erecting Welded Arch Buildings. R. L. GRAVELEY. *Welding*, Vol. 2, Mar. 1931, pages 175–176.

Deals with the design of arches, methods of erecting, types of welds used and system of inspection, by the Arch Engineering & Construction Co., Orlando, Fla. Ha(11c)

Fillet Welds Determined Graphically. JAMES R. GRIFFITH. *Welding*, Vol. 2, Mar. 1931, pages 163–165.

A monographic chart was developed which permits the determination of any of the 4 factors: unit shearing force, total load, total length of weld and size of fillet. Ha(11c)

Oxy-Acetylene Welding for Aircraft. LEROY R. GURLEY. *Welding*, Vol. 2, Feb. 1931, pages 95–96.

Proper procedure control removes the human element and places the responsibility for good welds on designer and inspector. Ha(11c)

Computing Fillet Weld Stresses. CHAS. H. JENNINGS. *Welding*, Vol. 2, Feb. 1931, pages 101–104.

Three methods are used at present for calculating the stresses occurring in fillet welds: (1) the conventional method, in which the weld is considered to transmit the load over its whole section; (2) the principal stress method, consisting mostly of tension or shear; (3) the resultant force method, which is the resultant force acting in the weld in order to develop the force in the individual members. These methods are analytically discussed; from the standpoint of obtaining satisfactory results, they can be arranged in the order 2-1-3. On account of the wide varieties in the results of the methods the author advocates the establishment of a definite method as soon as possible. Ha(11c)

Weld Design and Production. ROBERT KINKEAD. Ronald Press, New York, 1930. Cloth, $6 \times 8^1/_2$ inches, 108 pages. Price $4.00.

Users and, especially, prospective users of welding methods for joining parts of their production will find this book an excellent guide in forming their judgment as to when and how to employ this process. There is no question but that welding is, to-day, almost superseding every other form of joining parts and the fundamental, essential understanding of the behavior of welded joints—how to prepare, what to expect and how stresses can be calculated—is simply, but clearly, set forth by the author. Manual and automatic welding is discussed. The space dimension diagrams are a very good means of obtaining an insight into the distribution of stresses. Very timely is the chapter on "Research and Development," wherein the author points to the often-neglected importance of the choice of a personnel to carry on research work. Failures in this field can easily be traced to the improper selection of personnel. The good printing makes this treatise the more readable.—M. Hartenheim (11c)-B-

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Common Errors in Steel-Making. WALTER LISTER. *Metallurgia*, Vol. 1, Dec. 1929, pages 79–80; Jan. 1930, pages 103–104; Feb. 1930, pages 158–160 and 165; Mar. 1930, pages 200–202 and 214; April 1930, pages 247–249.

Discusses manufacture of steel in acid and basic open-hearths. The form of molds and casting practice is discussed. Methods for marking ingots and keeping records are given. JLG(12a)

Process Reliability in Steel Making. GEORGE A. DORNIN (Gathmann Engineering Co.) *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 100–128.

Paper presented before the 12th annual Convention of the Society in Chicago, Sept. 1930, with discussion. The author refers to 4 essentials for sound steel: (1) deoxidized bath before teeming; (2) ingot mold of proper dimensions; (3) keeping the ingot in a vertical position until completely solid; and (4) a refractory sinkhead, which he presented some years ago. He now proposes to amplify the first, the second and third stand with only slight modification and the fourth while not fundamentally essential is commercially necessary. The author refers to lack of control over the processes, by which large tonnages of steel are made, leading to unreliable metal. It is pointed out that the use of tests cannot be made to control an unreliable process. The results of substitution of basic process for the more reliable acid open hearth process in making cable for the Mount Hope Bridge is cited. Rimming steel, killing in the mold with Al, use of big end down molds, and welding are condemned as not reliable or susceptible of control. The author discusses his 4 fundamentals in detail and offers a duplex open-hearth process using a neutral slag for finishing as the solution of the first, the big end up type of mold is proper shape to prevent internal bridging and voids, failure to allow sufficient time for complete solidification results in woody structure, the refractory sinkhead feeds the shrinkage cavity and maintains a ferrostatic pressure on the crystal bridges and keeps them bent down. Shape of ingot section is discussed. In discussion H. H. Ashdown, Consulting Metallurgist, takes exception to fundamentals 2 and 4 and suggests the addition of "except under special conditions." W. H. White, Duquesne Steel Foundry, suggests the necessity for improvement in the personnel as well as in the process. T. M. Jasper, A. O. Smith Corp., finds much of the author's criticism of unreliable steel making methods is warranted by the experience of consumers. W. J. Priestley, Electro-Metallurgical Sales Corp. points out desirability of the properties of rimmed steels for certain applications and emphasizes the cost to the steel maker who must operate at a profit. WLC(12a)

Use of Zirconium Alloys in Steel Making. (De l'emploi des alliages au Zirconium dans la fabrication des aciers.) PH. GUY. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Nov. 1930, pages 509–521.

Ferro-silico-zirconium alloy has been used as deoxidizer and as alloying addition to steel. Zirconium has the property to form nitrides and to fix the sulphur, which is about $^1/_{10}$ of the amount of the zirconium added. The ratio Mn/S is reduced by the addition of Zr. Steels treated with only 0.04% Zr show an endurance limit higher than the steel treated with only FeSi. The effect of Zr on Izod number neutralizes that of phosphorus. GTM(12a)

New Manganese-Silicon Alloys for the Deoxidation of Steel. C. H. HERTY, JR. & G. R. FITTERER. *Bureau of Mines Report of Investigations* 3081, Feb. 1931, 14 pages.

By using manganese-silicon alloys for deoxidation, larger inclusions were formed than when using silicon alone. The average size of the inclusions formed when using silicon was 15 cm. $\times 10^{-4}$. The size increased with increasing manganese, until at a Mn/Si ratio of 4.18 the largest particles in dead-killed steels were 1000 cm. $\times 10^{-4}$. These large particles would rise at a much more rapid rate (600 to 2400 inches per minute) than the small silica particles (0.15 to 1.5 inches per minute). Tests in commercial acid or basic open hearths show the same results on steels from 0.12 to 0.60% C using alloys with a Mn/Si ratio of 4.5 to 6.0. Manganese efficiencies of 75 to 85% have been obtained when forging grade steels have been deoxidized with these alloys. AHE(12a)

Refining of Aluminum and Its Alloys by Treatment with Chlorine and Nitrogen. (Raffination von Aluminium und seinen Legierungen durch Behandlung mit Chlorgas und Stickstoff.) W. KOCH. *Metallwirtschaft*, Vol. 10, Jan. 23, 1931, pages 69–72; Jan. 30, 1931, pages 85–88.

Contains 5 references. Chlorine gas was passed for 5 to 15 minutes through molten Al alloys at 700° to 1100° C. The alloys contained from 0.8 to 12.6% Fe, 0.41 to 2.1% Si and 1.4 to 2.8% Cr. Silumin and commercial Al scrap were also treated. During the first few minutes Cl is absorbed by the metal, then the Cl escapes and some metal is also volatilized, but a protective coating forms on top of the metal. After treatment with Cl, N was passed through the metal to free it from Cl. The change in Fe and Si content due to this treatment is very slight. The effect of the Cl and N treatment is to reduce the gas content of the alloys considerably, purify the crystal boundaries, reduce the grain size and make it more uniform, increase the fluidity, produce tight, smooth castings with a fine fracture and raise the tensile strength, ductility and hardness. The best temperature for chlorinating is about 100° above the melting point of the alloy and the best time 7 to 8 minutes for a 10-lb. heat. The refining action of Cl is explained by the slight solubility of Al in Cl and the affinity of Cl for the metalloid impurities and the volatility of the chlorides formed. The process has commercial possibilities in the purification of Al scrap. CEM(12a)

DEFECTS (13)

Discontinuities. *Metallurgist*, Feb. 1931, pages 18–19.

The ill effects of sudden or sharp changes of section in any metallic part exposed to stress are, in principle, very fully recognized; yet practice frequently falls short of theoretical requirements in this direction. No doubt this is due to the fact that the requirements of design, or at all events the convenience of the designer, frequently seem to call for sharp "corners," especially in machine parts where the provision of a fillet of adequate radius entails a certain degree of awkwardness of construction. Moreover the addition of a considerable weight of metal to the parts in question to take care of any concentration of stress that may occur, may even aggravate the evil. Coker, in discussing Freeman's paper on the strength of welded joints recently given before the Institution of Civil Engineers, pointed out that where 2 overlapped pieces of steel are connected by fillet welds the interface of the 2 pieces acts practically as a crack or fissure and produces a stress concentration at the end of the fissure—i. e., at the weld itself. This stress concentration can, no doubt, be overcome by the adoption of a more rational form of welded joint, but its very existence has in all probability remained unrealized by those concerned with the design of welded joints. Heavy cuts in rough machining operations may leave a series of minute saw teeth at the roots of which there is often a fine fissure running a short distance into the metal. As a rule these are removed by the finer finishing cut but this is not always possible. Non-metallic enclosures, particularly when placed in a dangerous position, may initiate a fatigue crack. The number of non-metallic enclosures could be materially reduced if steel makers could be induced to lay stress on this aspect of their manufacture. VVK(13)

Non-Metallic Inclusions in Steel. I. S. GAIEFF. *Metallurgist*, Leningrad, Russia, No. 3, 1929, pages 369–399 (in Russian).

In a rather comprehensive paper, the author discusses the methods of preparation of specimens (grinding, polishing), the nature of inclusions, the methods of their identification and their effect on the structure and properties of metal. He divides non-metallic inclusions into the following main classes: (1) oxides, (2) sulphides, (3) silicates and slag inclusions. The color of inclusions, their hardness as well as the power to reflect light and their reaction to the action of the various etching reagents are used for identification of the nature of inclusion. It may be pointed out that at present there are about 40 chemical reagents used in mineralography. The author calls attention to the phenomena of diffusion of certain inclusions. If we take for example, a steel containing about 1% S and showing very fine particles of FeS, if we soak this steel for several hours at 1200° C. and cool slowly, we find that FeS inclusions disappear and instead of them flakes of Fe S are present. These flakes are arranged, sometimes, in a network manner. According to M. K. Ziegler, the rate of diffusion of sulphides at 1300° C. is of the following order: for FeS, 0.110 mm./hr.; for MnS, 0.003 mm./hr.; and for Mn S + Fe S an intermediate figure. In case of silicates, there were observed bands 0.005 mm. thick separating inclusions from the base metal. The author thinks that the presence of such "diffusion Zones" supports the suggestion made by Wohrman (Inclusions in Iron. C. R. Wohrman. *Transactions American Society for Steel Treating*, Vol. 14, 1928, pages 255–299.) that molten Fe is capable of being "silicatized." Sometimes non-metallic inclusions are present as the thin films surrounding the grains of the metal. Such films usually may be detected only under high magnifications (1000–2000 magnification). Examples are cited which show that inclusions serve as the nuclei upon which ferrite, cementite or troostite may be deposited. The paper is illustrated with many micrographs and contains 186 references. AIK(13)

CHEMICAL ANALYSIS (14)

Preparation of Some Organo-Mercuric Nitrates, and a Method of Analysis for Mercury Applicable to Dilute Solutions of Such Compounds. I. B. JOHNS, W. D. PETERSON & R. M. HIXON. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2820–2822.

A rapid method of analysis for mercury in the type compounds RHgX is described which is satisfactory even in the presence of iodides. MEH(14)

The Iodimetric Determination of Small Amounts of Zinc. H. ARMIN PAGEL & OLIVER C. AMES. *Journal American Chemical Society*, Vol. 52, Aug. 1930, pages 3093–3098.

Small amounts of zinc (3 to 33 mg. in 100 cc.) are precipitated as zinc pyridine thiocyanate, the thiocyanate treated with small excess of standard iodine and made alkaline with borax, and finally the solution is acidified and the excess iodine titrated with thiosulphate. Interferences of other metals and the details of the procedure are included. MEH(14)

The Detection and Estimation of Small Amounts of Lithium. EARLE R. CALEY. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2754–2758.

The method is based upon the reaction between ammonium stearate and lithium chloride in amyl alcohol solution and is a turbidometric procedure. Greater accuracy is claimed for this than for the gravimetric, when small amounts are to be estimated. MEH(14)

A Method for the Separation and Gravimetric Determination of Osmium. RALEIGH GILCHRIST. *Bureau of Standards Journal of Research*, Vol. 6, Mar. 1931, pages 421–448.

A procedure for the separation and gravimetric determination of Os is described. This procedure involves the separation of Os from other metals by distillation as the volatile tetroxide and its recovery from solution by hydrolytic precipitation. A very suitable reagent for the quantitative absorption of the distilled tetroxide was found to be 6 N HCl saturated with SiO_2. The recovery of Os was accomplished by precipitating the hydrated dioxide from a boiling solution at acidities ranging from pH 1.5–6.3, after sulphite compounds had been decomposed by repeated evaporation with HCl. The hydrated dioxide was impregnated with NH_4Cl to prevent mechanical loss when ignited to metal under hydrogen. The thiourea test devised by Chugaev for the detection of small quantities of Os was modified so that it could be applied to solutions containing HNO_3. The test was found to be sensitive to 1 part in 5,000,000 parts of solution, which is 50 times as sensitive as stated by Chugaev. (14)

Spectrographic Analysis Valuable in the Steel Plant. KELLERMANN. *Iron Age*, Vol. 126, August 7, 1930, page 359.

Abstract translation from *Stahl und Eisen*, Oct. 17, 1929. See *Metals & Alloys*, Vol. 1, July 1930, page 634. VSP(14)

Historical development of wire rope making. GN(15)

Who Invented Stainless Steel? (Wer hat den rostsicheren Stahl geschaffen?) E. MAURER (Freiberg). *Reprint, Technischen Blättern des deutschen Bergwerks-Zeitung*, Vol. 21, Nos. 12 and 13, 15 pages.

Polemic and historical discussion. While Hadfield, Guillet and Giesen (Maurer does not mention Becket, see *Mining & Metallurgy*, Vol. 9, 1928, page 551; Vol. 10, 1929, page 10) had made chromium steels that would have rust-resisting properties, they did not recognize those properties, and Monnartz, working under W. Borchers in 1908, may have been the first to recognize them. Maurer considers that Borchers and Monnartz, Dubois and Preher and Friend, Bentley and West marked out the way, and that Brearley, Hummelberger, Mauermann and Maurer all developed stainless steel independently. Maurer states that the other 3 antedated Brearley, but priority among the other 3 is not clear. However, Maurer feels that the finding of the suitable heat-treatment for making the steel fully corrosion-resistant, which he claims for himself, on the basis of experiments with Mn steel, was the crux of the whole matter. Other names mentioned in the history of Cr or Ni-Cr alloy steels are Pasel, Haynes, Berthier, Woods, Clark, Boussingault, Erdmann, Marsh, Dempster, Strauss, Goerens, Popp, R. Borchers, Dumas. The Pasel patents No. 304,126 and No. 304,159, of 1912 in Germany, appear to be the first clearly covering the present 18 Cr 8 Ni combination, with heat-treatment by quenching from 1100–1200° C., among those mentioned by Maurer, but Maurer claims that this heat-treatment would follow directly from his own. HWG(15)

ECONOMIC (16)

Mercury in 1929. PAUL M. TYLER. *Mineral Resources of the United States*, 1929, Part 1, Dec. 18, 1930, *United States Bureau of Mines*, pages 117–142.

In 1929 continued high prices stimulated activity in Hg mining and resulted in further increase in production from 17,870 flasks (1928) to 23,682 flasks of 76 lbs., derived from 63 mines. California led with 10,139 flasks, followed by Nevada with 4764, Oregon 3657, Washington 1397 and Texas, Arizona and Alaska 3725. A valuable survey of distribution of consumption is given. Drugs and chemicals account for 40% of the consumption and fulminate for blasting caps for 19%. No new uses were developed in 1929 except in Hg-containing solder reported in Great Britian. Production by states is discussed in detail. AHE(16)

The Present Situation of Aluminum Industry. (Situation de l'industrie de l'aluminium.) *Journal du Four Electrique*, Vol. 40, Jan. 1931, pages 14–15.

Aluminum industry did suffer in 1930, but not as much as that of most of the other metals. Producing and consuming countries were in better position than the exporters, particularly when tariff walls were introduced all around. JDG(16)

Preliminary Report on Goudreau and Michipicoten Areas. E. S. MOORE. *Canadian Minining Journal*, Vol. 51, Dec. 19, 1930, page 1224.

Gold developments of the season and drilling of Fe ore deposits are briefly outlined. WHB(16)

Chromite in 1929. LEWIS A. SMITH. *Mineral Resources of the United States*, 1929, Part 1, Mar. 5, 1931, *United States Bureau of Mines*, pages 203–229.

The United States produces a negligible quantity of chromite and imports over half the world's output. In 1929, 318,000 tons were imported, an increase of 101,000 tons over 1928. The outstanding metallurgical development was the increased use of Nirosta metal (18% Cr and 8% Ni in iron). The chromium-plating industry increased its production in 1929. In the United States 543 tons of chromite were mined (269 tons shipped). Details are given. 30 references. AHE(16)

Quinquennial Review of the Mineral Production of India for the Years 1924 to 1928. *Records of the Geological Survey of India*, Vol. 64, 1930, 446 pages.

Introduction. E. H. PASCOE, pages 1 to 3.

Summary of Progress. E. H. PASCOE, pages 4 to 25.

The output and value of all minerals and metals produced in India and imported into the country in 1924 to 1928 are tabulated.

Antimony. E. H. PASCOE, pages 26 to 28.

Antimonial lead (about 1000 tons a year) is being regularly produced from the Bawdwin mine in Burma. It analyzes approximately 77% Pb, 21% Sb and 6 to 8 oz. of Ag/ton.

Copper. E. H. PASCOE, pages 78 to 88.

Indian Cu production from 1924 to 1928 averaged about 20,000 tons per year.

Gold. G. DE P. COTTER, pages 92 to 106.

Indian gold production has been falling steadily since 1915. Average production for 1924 to 1928 was about 387,000 ounces.

Ilmenite. W. A. K. CHRISTIE, pages 109 to 111.

India is the world's largest producer of ilmenite.

Iron. H. CECIL JONES, pages 111 to 146.

The advance in the Indian iron and steel trade during this period was less than expected. Iron ore production averaged over 1,700,000 tons. The operations of individual steel companies are described.

Lead. G. VERNON HOBSON, pages 154 to 166.

The Bawdwin mine of the Burma Corporation is one of the greatest lead-silver-zinc mines in the world. Production from 1924 to 1928 averaged about 60,000 tons of Pb and nearly $5^3/_4$ million oz. of Ag.

Manganese. L. L. FERMOR, pages 172 to 233.

India is the world's leading manganese producer. The world economic situation is discussed.

Silver. G. VERNON HOBSON, pages 293 to 298.

Over 99% of the Ag production in India is from Pb ore. The government Ag refinery is described in detail.

Tin. J. COGGIN BROWN, pages 298 to 305.

The tin industry has steadily progressed during this period.

Tungsten. J. COGGIN BROWN, pages 305 to 310.

Burma tungsten production, inflated during the war, has collapsed.

Zinc. G. VERNON HOBSON, pages 310 to 312.

Zinc concentrates are produced at Bawdwin. Their amount is steadily increasing.

Arsenic. E. H. PASCOE, pages 320 to 322.

Bismuth. E. H. PASCOE, page 344.

Cobalt. E. H. PASCOE, pages 379 to 380.

There is a regular (small) production of cobalt from nickel speiss from the Burma Corporation.

Nickel. E. H. PASCOE, pages 412 to 413.

Nickel is a by-product in the smelting operations of the Burma Corporation.

Rare Minerals. W. A. K. CHRISTIE, pages 421 to 426.

Occurrences of platinum, iridosmine, molybdenite, rutite, beryl, various minerals of the rare earths, etc., are described. AHE(16)

Ore Deposits in Algeria. (Erzvorkommen in Algerien.) W. LUYKEN. *Stahl und Eisen*, Vol. 51, Jan. 22, 1931, pages 110–111.

An article by G. Bétier in *Revue de l'Industrie minérale*, 1930, pages 313–371, is reviewed. The origin and the amount of the ore deposits is discussed. GN(16)

PLANTS & LABORATORIES (17)

The Huntington Rolling Mill. H. S. ARNOLD & SHOFFSTALL (International Nickel Co.). *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1930, pages 493–494.

A description of the Huntington, W. Va., plant of the International Nickel Co. The raw materials employed are: Ni-Cu matte from the Canadian smelter and electrolytic Ni cathodes from the Port Colborne refinery. The final products are: Monel metal, and malleable Ni in the form of bars, rods, wire strip, sheets and tubes of all ordinary dimensions. A flowsheet is shown. WHB(17)

Lathe Transmission Gears. DONALD M. GURNEY. *Metal Progress*, Vol. 1, Sept. 1930, pages 68–70.

A description of production hardening methods used by the Warner and Swasey Co. in the manufacture of gears. A straight line installation of 2 salt pots, quenching oil tank, detergent kettle and air tempering furnace, served by a monorail air hoist constitute a unit of 250 lbs./hr. capacity. The steel used is S.A.E. 3150. WHK(17)

European Laboratories for the Testing of Materials. FRANKLIN L. EVERETT. *Mechanical Engineering*, Vol. 53, Mar. 1931, pages 201–204.

Observations covering the more important British and continental university and industrial laboratories devoted principally to research in the mechanics of materials. MFB(17)

British Insulated, a Great Cable Company. A. C. BLACKALL. *Wire & Wire Products*, Vol. 5, Oct. 1930, pages 422–423, 439–441.

Description of the plant, methods, equipment and products of the largest English cable making company. GN(17)

The Cardiff Blast Furnace Plant of the British (Guest Keens) Iron and Steel Company Limited. *Iron & Steel of Canada*, Vol. 14, Jan. 1931, pages 6–8.

A description of the blast-furnace plant and, in particular, of the No. 4 blast furnace recently erected at Cardiff, South Wales. This furnace was responsible for a record output of 4008 tons of iron in one week. A full description is given of the charging gear, main hoist, gas-cleaning equipment, stoves, casting equipment, blowing plant, boiler plant and raw materials used in manufacture of the iron. OWE(17)

A New Plant for Carburetor Production. *Brass World*, Vol. 27, Mar. 1931, pages 53–55.

An illustrated description of the foundry and machine shops at South Bend, Ind., of the Stromberg Motor Devices Co. Automotive and aircraft carburetors are made. WHB(17)

New Type of Deep Galvanizing Installation in Canadian Plant. *American Metal Market*, Vol. 38, Mar. 3, 1931, page 5.

At the Frost Steel & Wire Co., Hamilton, Ontario, an electrically-heated hot-dip galvanizing furnace features deep kettles with heat application at determined positions on the sides which result in great reductions in residuum losses and a uniformity in technique. The furnace which is illustrated lends itself to fully automatic and absolute control of temperature of 30–35 tons of molten zinc in the large kettle. A very superior product from the standpoint of bonding of zinc to the wire is claimed. WHB(17)

Precious-Metal Worker Uses Ten Electric Furnaces. *Electrical World*, Vol. 97, Feb. 21, 1931, pages 368–70.

At the plant of the D. E. Makepeace Co., Attleboro, Mass. ten electric furnaces are used for melting, annealing and tool hardening of Pt, Au and Ag alloys and of Au and Ag solders. The advantages of the electrically-heated over the fuel-fired annealing furnaces are freedom from oxidation and from sulphides on the surface of the Ag alloys. Direct annealing is applied by taking from a separate single-phase, 500-volt feeder, which is stepped down through a special transformer and a number of secondary taps to voltages varying between 8 and 64. Control of the secondary voltage is made by means of a set of removable busbars in combination with two sets of knife switches. Wiring details of the control panel are shown. WHB(17)

The Electrolytic Copper Refinery at Oolen. (La raffinerie electrolytique de cuivre d'Oolen.) R. SEVIN. *Journal du Four Electrique*, Vol. 40, Jan. 1931, pages 9–10.

A brief description of the most modern European copper refinery with a present capacity of 75,000 tons a year. No radical innovations were introduced in the design, but everything was planned according to the best practice. Another division of the plant handles preparation of bichromate and recovery of cobalt and radium. JDG(17)

Continuous Billet Normalizing Furnaces. C. B. PHILLIPS (Surface Combustion Co.). *Blast Furnace & Steel Plant*, Vol. 18, Mar. 1930, pages 452–453; *Heat Treating & Forging*, Vol. 16, June 1930, pages 781–782.

Describes a continuous, double-row, pusher-type, gas-fired billet heating furnace. It has preheating, heating and soaking zones, the parts being heated to 2300° F. It is provided with automatic combustion control. The normalizing furnace is of the same general type as the billet furnace. The highest temperature used in it is 1650° F. See also "Forging Practice Modernized by Mechanical Handling" in *Metals & Alloys*, Vol. 2, Jan. 1931, page 14. MS(17)

The New 5000-Ton Smelter. D. MACASKILL & R.M. COLEMAN (International Nickel Co.). *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1931, pages 473–477.

An illustrated description of the new International Nickel Co. smelter at Copper Cliff. Detailed flow sheets of the operations from the Frood and Creighton mines to the refinery are included. WHB(17)

MISCELLANEOUS (20)

On the Nature of Tensile Strength. (Ueber die Natur der Festigkeit.) H. KOTTE. *Stahl und Eisen*, Vol. 50, July 24, 1930, page 1071.

An article by M. Polanyi in *Metallwirtschaft*, Vol. 9, 1930, pages 553–558, on the above subject is reviewed. A general discussion of the difference between amorphous and crystalline state is given, pointing out that crystalline bodies have a distinct arrangement of atoms whereas amorphous bodies are distinguished by a non-uniform atom arrangement. This distinction then causes a different behavior in any process of deformation. Amorphous bodies cannot form sliding planes in deformation. The plasticity of amorphous substances is extremely dependent upon the temperature. GN(20)

Progress and Future of Chemical Engineering in Australia. N. V. S. KNIBBS. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 431–432.

Brief survey, metallurgical industries included. MPB(20)

Calculation of the Turning Moment of a Converter. (Die Ermittlung des Kippmonentes eines Konverters.) H. KÖNIG. *Archiv für Eisenhüttenwesen*, Vol. 4, Oct. 1930, pages 177–184.

Report 193 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The author finds through mathematical calculations that the axis of suspension of converters is almost always placed too high. He shows that over 50% of the hydraulic power can be saved in the example considered. GN(20)

Chemical Engineering in South Africa. WM. CULLEN. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 429–430.

Brief description, metallurgical industries included. MPB(20)

The Hardening of Superhardened Steel by Magnetism; the Lattice-Resonance Hypothesis. E. G. HERBERT. *Engineering*, Vol. 128, Nov. 1, 1929, pages 569–571.

Condensed from paper read before the Iron and Steel Institute, Sept. 12, 1929. *Metals & Alloys*, Vol. 1, Feb. 1930, page 390. LFM(20)

Studies on Zinc and Barium Ferrites. JOSEPH GUILLISSEN & PIERRE J. VAN RYSSSLBERGHE. *American Electrochemical Society, Preprint* 59–1, April 1931 Meeting, 11 pages.

The formation of zinc ferrite by the direct addition of zinc and ferric oxides was studied at various temperatures between 580° and 660° C. During the first 2 or 3 hours of heating, the reaction obeys Tammann's logarithmic law on reactions between solid phases. An apparent equilibrium appears afterwards. At 580° C. the reaction takes place extremely slowly. It is found by thermal analysis that there is no evidence for the formation of a compound containing more zinc oxide than $ZnFe_2O_4$, at least not below 1070° C. The solubility of zinc ferrite in 1N and 2N H_2SO_4 is studied. A mixture of 7.5% SO_2 in air, passed on zinc ferrite heated at 450° C., decomposes it slowly and liberates the zinc as zinc sulphate. The formation of barium ferrite resulting from the heating of a mixture of barium carbonate and ferric oxide was studied at 720° C. It also obeys Tammann's law. The apparent equilibrium towards which the reaction tends is destroyed when the mixture is stirred and heated again at the same temperature: the reaction goes on according to Tammann's law, the velocity of reaction being, however, considerably smaller than originally. The results are discussed and explained on the basis of diffusion. (20)

Small Jobs in the Running of Machinery in Steel Works. (Kleinarbeit im Maschinenbetriebe auf Hüttenwerken.) W. PAULING. *Stahl und Eisen*, Vol. 50, Aug. 14, 1930, pages 1153–1164.

Report 47 of the Committee on Machinery of the Verein deutscher Eisenhüttenleute. Includes discussion. The article points out how stoppages and breakdowns of machinery may be avoided by attention to lubrication and lubricating devices, protection of bearings against dust, use of roller bearings, case hardening of wearing surfaces, etc. GN(20)

The Diffusion of Ions of Salts in Aluminum. (Diffusion d'ions de sels dans l'aluminium.) M. J. CICHOCKI. *Comptes Rendus de L'Académie des Sciences*, Vol. 191, Nov. 10, 1930, pages 841–842.

The author refers to the experiments of Peczalski on the diffusion of salts in metals and to the fact that in penetrating the metals a thermionic current is produced. He describes experiments in this connection, which he has made with aluminum, using a tube of the metal having an internal diameter of 2 mm. and an external diameter of 4 mm. In his experiments $NiCl_2$ was used as the diffusing salt. The experiments with aluminum fell into line with those of Peczalski, except that the thermionic emission was positive. OWE(20)

The Periodic Arrangement of the Chemical Elements in 1930. C. E. FAWSITT (University of Sydney). *Chemical Engineering & Mining Review*, Vol. 23, Jan. 5, 1931, pages 152–153.

An abstract of an address on Nov. 26, 1930, at the annual meeting of the Australian Chemical Institute. The periodic arrangement of the chemical elements is tabulated. In recent years the following elements have been discovered: masurium, illinium, hafnium and rhenium. Hafnium is the only one found in any quantity. It is unlikely that the electronic arrangements as now accepted will be greatly altered in the future. Isotopes are best considered as separate elements. WHB(20)

Diffusion and Distribution in a Solvent of Graded Composition. G. S. HARTLEY. *Transactions of the Faraday Society*, Vol. 27, Part 1, Jan. 1931, pages 10–29.

The author describes experiments designed to determine the distribution of a molecular solute in a solvent having a gradient of some other property, namely a gradient of concentration of a second solute. No evidence was obtained that the distribution of a solute free to move in a maintained gradient of composition is affected by forces other than those internal ones which govern solubility and the dynamic effect of the diffusing components. Diffusion from regions of higher to those of lower diffusion velocity independently of these factors does not apparently occur. The statistical effect examined theoretically by Chapman (*Proceedings Royal Society*, Vol. 119A, 1928, page 34) must, therefore, be included in the solubility theory. Further, the factors leading to increase of diffusion velocity must also tend to decrease solubility. OWE(20)

Theories of the Soret Effect. G. S. HARTLEY. *Transactions Faraday Society*, Vol. 27, Jan. 1931, pages 1–10.

A number of kinetic theories of the Soret effect are reviewed and the error common to all is pointed out. It is shown that it is impossible to formulate a valid theory if use is made of standard thermo-dynamic functions only. Independent support is given to Eastman's theory of effect. OWE(20)

A Note on the Preparation of Silver-Free Copper. BART PARK. *Journal American Chemical Society*, Vol. 52, Aug. 1930, pages 3165–3166.

Commercial copper sulphate was recrystallized 3 times. A spectrogram made from it showed about 0.004% Ag. An acid solution of this salt was electrolyzed slowly, seven fractions obtained by deposit; these were dissolved in nitric acid, converted to the oxide by heating, and the oxide reduced by hydrogen in a silica tube. Electrodes were made from the melted copper and tested. The spectrograms showed no trace of silver line at 3281. MEH(20)

Oxidation Reduction Potentials at Carbon and Tungsten Electrodes. LOUIS B. FLEXNER & E. S. GUZMAN BARRON. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2773–2776.

Graphite and tungsten electrodes have been tested in oxidation–reduction systems. In the quinhydrone system graphite gives results identical with those obtained at blank Pt and Au-plated Pt; whereas W gives entirely different results. In the ferro–ferricyanide system graphite gives measurements 1 to 2 millivolts less than Pt, whereas those with W are 5 to 10 mv. less. In a dyestuff system, well or poorly poised, graphite gives the same results as Pt; W gives reliable values only when the system is well poised. The potentials of graphite and W against a reversible dye system are unaffected by change from a nitrogen to a hydrogen atmosphere. MEH(20)

A Study of Losses in the Transport System of a Drop Forge. (Untersuchung über Förderverluste in einer Gesenkschmiede.) W. SCHÖNING. *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 45–54.

The article deals with the economies to be effected by means of a rational transport system in a drop forge. GN(20)

The Chemist in the Metallurgical Industries. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 435–441.

A description of the processes carried on at the Henry Wiggins and Co. plant at Birmingham, England, where nickel alloys are made. MPB(20)

200,000-KW. Mercury-Vapor Power Plant for Schenectady. *General Electric Review*, Vol. 34, Feb. 1931, page 142.

Construction work has started for the erection of a large mercury-vapor power plant. It will be the first outdoor steam plant, one of the first plants to have coördinated industrial requirements and utility sources of power. Besides the 2000-kw. mercury boiler and turbine the new station will include a steam boiler to supply 300,000 lbs. of steam per hr. from the mercury condenser, for process heating and testing steam in the General Electric Works. A large part of the power generated from the mercury turbine is obtained at very high efficiency. The boiler will require 250,000 lbs. of mercury. WHB(20)

FOUNDRY PRACTICE & APPLIANCES (22)

Status of Foundry Sand Control as Seen by the Sand Producer. W. WORLEY KERLIN. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Aug. 1930, pages 373–384.

The quality of new sand determines to a large extent the venting factor, strength and temper of molding sand. For control, the sand producer must know the chemical analysis, the amount of colloidal bond and the screen analysis of his deposits. CHL(22)

Some Observations on Preparation and Use of Synthetic Sand. L. B. KNIGHT. *American Foundrymen's Association, Preprint* No. 31–8, 1931, 10 pages.

Author emphasized the need for information on the preparation of synthetic sand. To use the material, definite standards of permeability, bond strength and moisture content must be established and maintained. CHL(22)

Molding Practice in the Foundry. (Die Formpraxis in der Metallgiesserei.) E. BECKER. Heft 14 of H. Hermanns' series on Works Practice in the Iron, Steel and Non-Ferrous Foundry. Wilhelm Knapp Verlag, Halle (Saale), 1931. Paper $6^1/_4 \times 9^1/_4$ inches, 112 pages. Price 8.50 RM.

A very elementary treatise, about what one would expect to be used as a test in a manual training course in a grade school. It illustrates such things as slicks and rammers and some simple molding machines. Sweep molding and the lost wax process are given brief mention. The scope of the work may be judged from the 3 pages on the testing of molding sand, which certainly tell very little, and part of that is not very helpful in that it carries the idea that electrical resistance measurements will satisfactorily indicate moisture content.—H. W. Gillett (22)-B-

Progress in Gray Iron Castings. HYMAN BORNSTEIN. *Metal Progress*, Vol. 1, Oct. 1930, pages 43–46.

A discussion of the modern trends in the production of cast iron. Closer carbon control and/or alloy additions of Ni and Cr yield castings of 60,000 lbs./in.^{2} tensile strength. Heat treatment also briefly discussed. WHK(22)

Some Recent Advances in the Field of Foundry Sand Control. A. A. GRUBB. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Dec. 1930, pages 34–46.

Author briefly considers factors which are responsible for foundry sand troubles. CHL(22)

Some Responsibilities of the User in Obtaining the Best Product of the Steel Foundry. R. A. BULL. *Research Group News* (Electric Steel Founders' Research Group), Vol. 7, Jan. 1931, pages 352–362.

Diversity in surface finish; range of physical properties; comparing cast steel with other material; casting design; pattern equipment; advice for the producer, are principal topics covered. MFB(22)

Simple Methods for Improvement and Control of Gray Iron Manufacture. L. F. C. GIRARDET. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Nov. 1930, pages 624–643.

Control operations are divided into 3 classes; (1) mechanical properties; (2) metallographic structure; and (3) chemical analyses. Fremont shear test is advocated as showing properties of the casting. CHL(22)

Value of Analysis and Specification for Core Oils. J. A. GITZEN. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, July 1930, pages 97–106.

If the iodine number is 180 or over, any drying or semi-drying oil, except fish oil, may be used to replace linseed oil in cores. CHL(22)

Deep Etching of Brass Applied to Gating Problems. R. W. PARSONS. *American Foundrymen's Association, Preprint* No. 31–11, 1931, 10 pages.

Defects arising from improper gating of brass castings are revealed by deep etching. Regating of globe-valve castings after investigating causes for leaks by the deep etching method reduced the losses to a minimum. Conclusions regarding metal conditions from etched sections of dissimilar castings cannot be drawn. CHL(22)

Gating Iron Castings. E. M. HANDLEY. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Feb. 1931, pages 29–36.

Gate area, position of gate on casting, and pouring temperature of cast-iron are essential factors that control the soundness of castings. The mathematical expressions derived by Dietert for determining gate area and pouring time are illustrated. CHL(22)

Reducing Materials-Handling Costs in Jobbing Foundries. F. D. CAMPBELL. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Oct. 1930, pages 541–560.

Production and annual earnings are increased by proper planning, arrangement and installation of labor-saving devices in foundries. CHL(22)

Notes on Behavior of Sand Molds in Steel Foundries. PAUL L. GOODALE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Sept. 1930, pages 471–480.

Characteristics and properties of core surfaces when casting steel against them were studied. Oxide of iron penetrates the sand to form some iron silicate. The author has various ideas to overcome slag formation which presents difficulties in obtaining smooth steel castings. CHL(22)

Up-To-Date Methods in the Stove Foundry. JAS. BREAKEY. *Canadian Foundryman*, Vol. 22, Feb. 1931, page 7.

A description of methods used in the manufacture of stoves of various descriptions, as carried out by the McClary Manufacturing Co., London, Ont., a subsidiary of General Steelwares, Ltd. Special attention is given to a stove-top polisher. Article is illustrated by four photographs. OWE(22)

Electric Process Iron for Cylinder and Cylinder-Head Castings. H. E. BROMER. *American Foundrymen's Association, Preprint* No. 31–13, 1931, 15 pages.

Duplexing of cast iron during high-production period proved economical. Strengths of 40,000 lbs./in.^{2} were obtained for gray iron made in this manner while alloyed irons were obtained with strengths of 60,000 lbs./in.^{2} CHL(22)

Core-binders. H. H. EBERT. *Iron & Steel Industry & British Foundryman*, Vol. 3, Sept. 1930, pages 363–364.

A discussion of natural and artificial core-binding materials and their uses are given. CHL(22)

Die Castings for Economy in Production. D. L. COLWELL. *Metal Progress*, Vol. 1, Sept. 1930, pages 91–95.

A review of the materials and methods used in die casting with considerations of their advantages and limitations. WHK(22)

Superheating of Cast Iron. (Ueberhitzung von Gusseisen.) P. BARDENHEUER & K. L. ZEYEN. *Giesserei*, Vol. 16, Aug. 16, 1929, page 733; *Metallurgist*, Sept. 27, 1929, pages 141–142.

See *Metals & Alloys*, Vol. 1, Dec. 1929, page 293. (22)

The Most Potent Variable. GEO. BATTY. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Aug. 1930, pages 309–331.

Deficiences of the molding sand are the cause of most defects in steel castings. The importance of the following factors relating to molding sand are discussed: grain shape and size, surface area covered by binder, bond additions, permeability of facing and backing material, surface moisture and pouring temperature. CHL(22)

A Comparison of Natural Bonded and Synthetic Molding Sands for the Steel Foundry. H. J. COLE. *American Foundrymen's Association, Preprint* No. 31–10, 1931, 9 pages.

A comparison is made of the properties of synthetic and natural bonded steel molding sands as used in actual plant practice. Physical properties of the sands and clays used are given. CHL(22)

Design of the Modern Cupola Calls for Study. *Canadian Foundryman*, Vol. 22, Mar. 1931, pages 7–9.

An article dealing with the design of cupolas, in which tables are given, showing the capacity ratings and overall dimensions of some of the leading standard cupolas of the present day. Methods now adopted in the building of the cupola shell and in the support of the cupola are discussed, and the designs of tapping and slag spouts, wind belts, and tuyères are dealt with. OWE(22)

Continuous Melting from Cold Stock of Gray Iron in Electric Furnace. N. L. TURNER. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Jan. 1931, pages 749–760.

The use of a 3-ton electric furnace operating continuously increased the production per floor and decreased the cost of molding equipment. The charge consisted of cast-iron borings, shop scrap and steel clippings plus alloy additions. The ideal analysis of iron is given as C 3.25 to 3.35%; Si 2.75 to 2.85%; Mn 0.45 to 0.60%; P 0.60 to 0.70%; and S less than 0.09%. CHL(22)

Some Considerations in Gating and Pouring Castings. E. V. RONCERAY. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, May 1930, pages 41–64.

Four conditions under which there will be no piping in castings: (1) when the casting is at constantly uniform temperature; (2) when cooling progresses by parallel layers; (3) when no change in volume occurs; and (4) when metal is fed through heads to prevent shrink cavities. Various methods of gating to produce results approaching one or another of the conditions are taken up. CHL(22)

Factors Which Influence the Surface Quality of Gray Iron Castings. W. G. REICHERT & D. WOOLLEY. *American Foundrymen's Association, Preprint* No. 31–7, 1931, 27 pages.

The quality of the surface of castings as affected by varying conditions of grain fineness, moisture content, mold hardness, sea coal additions, increase in clay content, method of ramming, pouring temperature and fluidity of the metal was determined for sands of various A. F. A. classifications. The main factors that influence surface quality are grain size and moisture content. CHL(22)

Briquetting Cast-Iron Borings for Use in the Cupola. HARRY RAYNER. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Sept. 1930, pages 460–470.

The loss on melting briquettes is about that of cast-iron scrap. As much as 25% of total melt in the form of briquettes is used regularly without difficulty. CHL(22)

Profitable Reclamation of Sand in the Steel Foundries. M. D. PUGH. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Aug. 1930, pages 289–308; Discussion, pages 321–331.

"Burning in" of sand results from lack of uniformity of sand grains, quality of clay and the water present. Sizing tests of many sands are shown by curves. Reclamation and some failures in reclamation of steel molding sands are discussed. CHL(22)

Carbon and Sulphur in the Cupola—Some Properties of Coke. JAMES T. MACKENZIE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Sept. 1930, pages 385–432.

An equilibrium total C content is obtained under given cupola conditions depending on the coke used. A series of tests were carried out using 6 different cokes and various metal charges one variable changing in each heat. Effects of repeated melting were made by repeatedly using the same material. Data on changes in chemical analyses; the Brinell hardness; chill depth; temperature and blast variation; modulus of rupture and modulus of elasticity were tabulated and discussed. CHL(22)

The Founding of High Melting Point Alloys. J. MCNEIL. *Metal Industry*, London, Vol. 35, Nov. 22, 1929, page 489; Nov. 29, 1929, page 522.

Discussion *Foundry Trade Journal*, Vol. 41, Dec. 5, 1929, pages 407–408. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 431. (22)

Effect of Excessive Atmospheric Moisture in Cupola Blast. NEIL A. MOORE. *American Foundrymen's Association, Preprint* 31–2, 1931, 14 pages.

Refrigerating system was installed for controlling moisture in the cupola blast. Author believes that excessive moisture increases the chilling tendencies of cast iron. He also believes that excessive moisture increases the oxygen content of the iron and thereby retards the breaking down of cementite into ferrite and graphite. CHL(22)

Can Steel Founding Become an Exact Science? F. A. MELMOTH. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Mar. 1931, pages 21–35.

Control of materials, the exact predetermined series of molding operations, the control of solidification, and improved ideas on gating and feeding are essential and will come about through application of scientific principles. The industry still suffers from out-of-date thought. CHL(22)

Cupola High-Test and Alloy Irons in a Machine Tool and Gray Iron Jobbing Foundry. L. M. SHERWIN & T. F. KILEY. *American Foundrymen's Association, Preprint* No. 31–4, 1931, 42 pages.

Problems relating to pouring, gating and feeding of high-test iron castings are discussed. Effects of Mo, Ni and Cr in the iron mixtures are described. CHL(22)

Effect of Heat on the Permeability of Natural Molding Sands. WALTER M. SAUNDERS & WALTER M. SAUNDERS, JR. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, July 1930, pages 259–272.

The permeability of different sands have been studied in a simple device for measuring permeability at temperatures up to 1000° C. The effect of steam and expansion of sand grains on permeability is demonstrated. CHL(22)

Carbon Is Controlled in Synthetic Gray Iron. EDWIN BREMER. *Foundry*, Vol. 58, Nov. 15, 1930, pages 51–52.

Describes method used by Robbins & Myers, Inc., Springfield, Ohio for disposing of their sheet scrap. The sheet steel scrap was melted in rocking type electric furnace with addition of ferrosilicon and petroleum coke. Absorption of C by molten metal involves the length of time the 2 are allowed to react and the weight of coke added. C and Si in resulting iron may be varied to meet any desired range. Si usually ranges from 2.0–3.50% and C from 2.5–3.5%. VSP(22)

Aspects of Carbon Control in the Cupola. H. W. KEEBLE. *Metallurgia*, Vol. 3, Feb. 1931, pages 147–148.

The carbon content of the cast metal depends on (1) initial total carbon content of materials charged, (2) general cupola operation, (3) atmosphere at the melting zone, (4) time of contact with the fuel. An example is given which shows that over an extended period the carbon content of the iron was almost independent of the carbon content of the charge. Directions for producing a low C iron are given. Contains 6 references. JLG(22)

FURNACES & FUELS (23)

Furnace Insulation. A. E. HUBBARD. *Industrial Chemist*, Vol. 6, Nov. 1930, pages 465–466.
The importance of proper insulation for metallurgical and other furnaces is pointed out and the characteristics of suitable insulation materials are discussed. MPB(23)

Fuel Oil for Pot Annealing of Wire. R. S. COULTER. *Wire & Wire Products*, Vol. 5, June 1930, pages 215–217.
Description of furnaces, oil system, burners and other equipment for pot annealing of wire. Operating results are given and economics discussed. GN(23)

Artificial Atmospheres for Electric Furnaces. A. N. OTIS (General Elec. Co.). *Iron Age*, Vol. 126, Sept. 25, 1930, pages 844–848.
The H content of the atmosphere prevents oxidation of the product and the small methane content prevents decarburization. Tests showed that coils of 0.55% C wire heated to 1300° F. and held for 8 hrs. showed no scale or decarburization under the microscope. Electric furnaces equipped with electrolene may be used for annealing sheets, bars, wire and similar products. Furnaces may be designed to meet a variety of conditions, with a minimum of heating time and floor space. Advantages to be gained by the use of gases in industrial operations are manifested. VSP(23)

The Utilization of Waste Heat in the Steel Industry. CHARLES W. E. CLARKE. *Yearbook American Iron & Steel Institute*, 1930, pages 94–120.
Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 855. (23)

Electric Furnaces for Heat Treatment. (Sur les fours electriques de traitment thermique.) JEAN DESMURS. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Aug. 1930, pages 354–359.
Advantages, description and future of electric furnaces for heat treatment are discussed. For temperatures up to 1000° C. the elements in the resistance furnace are made of non-oxidizing Ni-Cr alloys. The manufacturers guarantee this alloy for 3000 hours at 950° and of indefinite service at 800° C. For higher temperatures than 1000° C. the elements consist of graphite or compounds of carborundum. Developments in Melting and Annealing Non-Ferrous Metals. ROBERT M. KEENEY. *Fuels & Furnaces*, Vol. 8, March 1930, pages 331–333.
Abstract of a paper read before the American Institute of Mining & Metallurgical Engineers, Feb. 17–21, 1930. See *Metals & Alloys*, Vol. 1, May 1930, page 526. MS(23)

Practical Points on Furnace Design. JOHN C. KIELMAN. *Metal Progress*, Vol. 1, Sept. 1930, pages 58–63.
A general discussion of the design and materials entering into the construction of furnaces, particularly of the fuel fired type, for diversified metallurgical applications, such as forging, hardening, annealing and carburizing. WHK(23)

High Frequency Furnace in Steel Making. (Le four á induction á haute frequence en acierie.) M. GUTMANN. *Aciers Speciaux, Métaux et Alliages*, Vol. 3, Special No., 1928, pages 518–526.
Principles and technical description of installations. Qualities of high frequency. Actual application of high frequency furnace. The metallurgy of high frequency furnace is discussed emphasizing the advantages in using this furnace for making quality steel. GTM(23)

Furnaces for Annealing, Galvanizing and Japanning of Strip Steel. J. B. NEALEY. *Wire & Wire Products*, Vol. 6, Feb. 1931, pages 47–49, 75–78.
Illustrated description of continuous furnaces with automatic control for annealing, galvanizing and japanning of strip steel. GN(23)

Electric Furnaces and Low-Temperature Treatments. J. E. ORAM. *Metallurgia*, Vol. 3, Jan. 1931, pages 94–96.
Electrically heated furnaces equipped with a fan for air circulation are ideal for tempering, nitriding and heating non-ferrous alloys. JLG(23)

Industrial Electric Heating for Railway Shops. W. S. SCOTT. *Railway Mechanical Engineer*, Vol. 105, Feb. 1931, pages 59–62, 65.
A study of electrical heating equipment in use in the Norfolk & Western shops at Roanoke, Va., with costs of operation and savings effected by its use. Description of the tool heat-treating department, carburizing furnaces and annealing steel castings. GN(23)

The Calculation of Heat Accumulators. (Die Berechnung der Wärmespeicher.) K. RUMMEL. *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 367–374.
Report 147 of the Heat Committee of the Verein deutscher Eisenhüttenleute. The method of calculation of heat accumulators is developed and considered in detail for the checkers of an open hearth furnace. GN(23)

Electric Furnace Cut Insurance Cost 38 Per Cent. *Electrical World*, Vol. 97, Mar. 28, 1931, page 641.
The Enamel Products Co., Cleveland, Ohio, derived this benefit from the installation of electric furnaces in place of fuel-fired equipment. Continuous types of furnace are used for baking enamel on sheet steel (table tops, tub tops, etc.). WHB(23)

Induction Furnaces for Nonferrous and Iron Foundries. MANUEL TAMA. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Sept. 1930, pages 433–440.
The 3 types of induction furnaces are described. An important development is the use of the induction furnace in conjunction with the cupola to superheat cast iron. CHL(23)

Use of Coal Gas in the Heat Treatment of Metals. (Considerations sur l'emploi du gaz de houille dans les traitments thermiques des metaux.) CH. TIXIER. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Aug. 1930, pages 348–353.
Discussion of economical and technical importance in using coal gas for heat treatment in small furnaces. GTM(23)

Electric Recuperative Furnaces at Citroen Plant. (Les fours electriques a recuperation aux usines Citroen.) *Journal du Four Electrique*, Vol. 40, Jan. 1931, pages 11–13.
Citroen company recently installed 2 continuous counter-current heating furnaces for carburizing work. Structural features and expense sheet are given for old and new installations. JDG(23)

Some Notes on the Use of Gas in Industrial Furnaces. F. A. MCLEAN. *Iron & Steel of Canada*, Vol. 14, Feb. 1931, pages 25–26.
The author discusses the use of burners for the combustion of illuminating gas in industrial furnace operation and particularly the latest type of high-pressure air system developed by New Jersey Meter Co., of Plainfield, N. J. The induction blower used in this system is given special attention, and details are quoted of the various sizes of blower available. OWE(23)

Gas Furnaces for Carburizing. W. F. CHUBB. *Automobile Engineer*, Vol. 19, Dec. 1929, pages 496–497.
Notes on installation of the Moss Gear Co., Ltd. Furnaces for carburizing cam shafts, gears and other automobile parts. Charging machine slots provide outlets for gases. Other changes are noted. Comparative costs are only slightly in favor of the gas furnaces over the electric furnaces. RHP(23)

Electrothermics. (Elektrothermie.) M. PIRANI. Julius Springer Verlag, Berlin, 1930. Cloth, 6 × 9¼ inches, 293 pages, 268 figs. Price 36 RM.
The sub-title of this book is "The Electrical Production and Technical Use of High Temperatures." It deals primarily with types of electric furnaces, rather than with the chemistry or technology of their use. For instance, one will get an idea of the various kinds of electric furnaces used in steel melting, but very little about the ways in which the actual operation of such a furnace resembles or differs from that of an open-hearth.
Obsolete furnace types and descriptions of furnaces that never existed save on paper in patent specifications are less in evidence in this book than in some older German books on the subject, though the section on fused quartz is largely taken from patent literature, and that on gases features the Pauling furnace for nitrogen fixation to a degree that seems scarcely justified by its present degree of technical importance. In some of the sections, the comments on American use of various types of furnaces are not necessarily very accurate.
On the whole, the book is instructive and pretty well up to date on what it covers. It is well printed and illustrated, but has no index, only a one-page table of contents. References to other literature are almost lacking.
Besides the sections by Pirani himself, others are written by R. Gross, M. Tama, R. Schneidler, F. Singer, H. Pauling and G. Keinath.
The usual subjects in a text-book of this nature are included, viz., furnaces for steel melting, iron ore smelting, ferro alloys, carbide (very brief treatment of the last three), non-ferrous melting, silicon carbide, fused alumina and electrically melted cement, graphite, quartz and nitric acid. Electrothermic research methods (chiefly a description of laboratory furnaces) and electrical measurements are also described, these last two sections occupying a third of the book. Furnaces of the types used in heat-treatment of steel and similar uses are not treated in this volume.—H. W. Gillett (23)-B-

The Present State of Carbonization at Low Temperatures and Preparation of Artificial Anthracite. (Etat present de la technique de la carbonization a basse temperature et de la preparation d'anthracites artificiels.) CH. BERTHELOT. *Revue de Metallurgie*, Vol. 27, Dec. 1930, pages 672–679.
England leads in low temperature carbonization by making about 11,000 tons daily. France is beginning to install units as large as 250 tons per day and the industry seems to have a promising future. Artificial anthracite is made at Mines de Noeux by treating a mixture of coke and tar with steam superheated to 650°. The greatest obstacle of the industry is the smallness of the individual units running the overhead too high. The requirements for successive operation and the cost both of installations and successful operation for different capacities are given. JDG(23)

Use of Washed Furnace Gas Promotes Economy. W. A. HAVEN & C. B. THORNE (Arthur G. McKee & Co.). *Steel*, Vol. 87, Dec. 4, 1930, pages 54, 56, 59.
Paper read before Iron and Steel Division of the American Society of Mechanical Engineers. MS(23)

Calculations for an Electrical Resistor Furnace. (Note sul calcolo dei forni elettrici a resistanza.) R. LEVI. *La Metallurgia Italiana*, Vol. 9, April 1931, pages 292–302.
Discussion of the theory of calculations for design of resistor furnaces, with an example of its application to an actual furnace. HWG(23)

Average Life of Electric Furnace Roofs. S. KRIZ & H. KRAL. *Iron Age*, Vol. 126, Dec. 11, 1930, page 1775.
Abstract translation of article in *Stahl und Eisen*. Gives data on the influence of the age of an electric furnace on the length of the heat and energy consumption. VSP(23)

Galvanizing Furnace Using Both Direct and Indirect Heating. HARRY E. GILBERT. *Iron Age*, Vol. 126, Sept. 18, 1930, pages 771, 828.
Describes furnace designed for heating galvanizing kettle which uses radiation, convection and conduction methods of heat transfer. Silicon carbide bricks are used for protecting and heat storage walls. Adapted to the use of either gas, oil or electricity. Operating cost is very low. Accumulation of dross in %, based on spelter charged, is likewise very small. VSP(23)

2000-Kw. 75-Ton Furnace Anneals Large Castings. A. G. HOTCHKISS. *Electrical World*, Vol. 38, Apr. 25, 1931, page 768.
At the Schenectady Works of the General Electric Co. a 2000-kw. car-bottom type electric annealing furnace with a maximum loading capacity of 75 tons has been installed. The loading space of the car is 27 ft. × 17 ft. × 12 ft. The furnace roof is of flat arch construction and the walls are of standard furnace construction. The heating units are of Ni-Cr ribbon resistor type and are located on all walls and ceiling of the furnace and bulkhead and floor of the car. Floor units are protected by cast-alloy hearth plates. The heating units are divided into eight zones or sections each separately controlled. The use of a light weight refractory has considerably shortened the heating and cooling cycles. The openings in the roof are opened and closed from the operator's booth by a chain and sprocket connection. WHB(23)

Mixed Gases Promote Economy in Steel Making. WILLIAM C. BUELL, JR. *Steel*, Vol. 87, Aug. 7, 1930, pages 54, 57, 60; Aug. 21, 1930, pages 50, 52, 54, 56.
Blast-furnace gas has no use outside of the steel plant other than its flow as electrical energy into the network of the public service system. In the plant, it has been used largely under the boilers, and in the heating stoves. Coke-oven gas, however finds a ready market. By mixing blast-furnace gas with coke-oven gas for use in open hearth furnaces, reheating-furnaces, soaking-pits, etc., a large portion of the coke-oven gas would be released for profitable sale. Presents tables and charts showing the effect of varying the volume ratio of the two gases on the calorific intensity of the resulting mixed gas and the thermal capacity characteristics of the gases. MS(23)

High-Frequency Furnace as New Means of Production in Steel Works. (Hochfrequenzofen als neues Stahlwerks—Produktionsmittel.) N. BROGLIO. *AEG Mitteilungen*, Vol. 4, Feb. 1931, pages 37–42.
The furnace is of the coreless type; it is built by bringing the material of the crucible (furnace) in dry powder form between a metallic cylinder and the heat insulation of the coil; the powder is tamped tightly after filling and then sintered together by slowly heating it inductively so that finally a dense crucible or container results, into which the batch is placed. The furnace is heated by a single phase current of 150 amp. at 1200 volts and 2000 cycles from a special motor-generator set. To compensate the very low power factor of such circuit, a battery of condensers is connected in parallel to the furnace circuit; according to the load conditions, more or less of these condensers are automatically connected, which keeps the power factor almost constant at unity. From tests, the consumption, including efficiency of MG-set and transformer, was found to be about 720 Kwh./ton when charged with cold batch; time required for melting was about 85 min., in average, from start to pouring for a charge of 300 kg. The average efficiency of the electrical plant was found to be about 72%. A detailed description of the installation and working conditions is given. Ha(23)

Bake Cylinder Block Cores in Continuous-Ovens. E. W. BEACH (Campbell, Wyant & Canon Foundry Co.). *Foundry*, Vol. 58, Dec. 15, 1930, pages 56–59.
Abstract of article in "Industrial Oven Notes". Describes the construction of ovens of the Campbell, Wyant & Canon Foundry Co., Muskegon, Mich. Two types of ovens are used, namely, horizontal and vertical. VSP(23)

REFRACTORIES & FURNACE MATERIALS (24)

Special Refractories for Metallurgical Research. DONALD TURNER. *Transactions Faraday Society*, Vol. 27, Mar. 1931, pages 112–124.

A description of refractory materials and technique of their use as practised at the National Physical Laboratory. Alumina, thoria, magnesia, lime, chromite and clay mixtures are used. Thermocouple tubes are extruded using a cellulose acetate solution with the powdered materials. PRK(24)

High-Silica Retorts at the Rose Lake Smelter. G. L. SPENCER, JR. (American Zinc, Lead & Smelting Co.). *Technical Publication* No. 378, *American Institute Mining & Metallurgical Engineers*, 1931, 6 pages.

Silica flour is added to the fireclay-grog mixture to produce a retort of high strength, which enables the use of a longer retort without danger of sagging. The analysis of 1 retort mixture in % was: 5.59 ignition loss, 66.06 SiO_2, 24.22 Al_2O_3, 2.96 Fe_2O_3, 0.56 CaO and 0.52 MgO. JLG(24)

Refractory Materials for Electric Furnaces. I. The Melting of Lead and Its Alloys. ALFRED B. SEARLE. *Metal Industry*, London, Vol. 38, Jan. 2, 1931, pages 3–4.

The maximum temperature attained in an electric furnace when melting Pb or Pb alloys is about 1000° and generally much lower. Electric furnaces consisting essentially of a crucible or single-piece lining, a heating element and a casing are the most suitable for melting this class of alloys. The properties of various refractory bricks are outlined and the suitability of magnesia brick for parts of a Pb furnace in contact with slag. For most induction furnaces dead-burned magnesia is best with pitch or colloidal magnesia as binding agent. A melted mixture of lead oxide and clay applied as a paste affords a means of overcoming the difficulty of using high-frequency furnaces for these fusible alloys. Silica bricks are used in the roofs. Most refractory materials are good conductors of electricity at red heat, which often results in serious leakage of current and may cause a serious defect in the furnace. WHB(24)

Highly Refractory Building Materials for the Metal Industry. (Hochfeuerfeste Baustoffe für die Metallindustrie.) W. STEGER. *Metallwirtschaft*, Vol. 9, June 20, 1930, pages 528–532.

Fireclay, silica and magnesite are the most commonly used refractories, but are not suitable for very high temperatures. Bauxite and diaspor, containing 45–80% Al_2O_3, have been used somewhat in basic open hearths and Pb smelting furnaces. Their melting point is SK 36–38 and they do not have very good strength at high temperatures. Mullite, 3 Al_2O_3.2 SiO_2, containing 72% Al_2O_3 and 28% SiO_2 is the only chemical compound of Al_2O_3 and SiO_2. Sillimanite, Al_2O_3.SiO_2, forms mullite and excess SiO_2 when burned. These materials have become very important refractories recently. Both the natural and synthetic products are used. A synthetic mullite made by fusing the materials in an electric furnace, pouring into molds and slowly cooling, similar to glass annealing, gives excellent results. High cost is a disadvantage and further investigation is necessary. Artificial corundum, made by fusing bauxite, with a proper binder, is an excellent refractory, but on account of high cost has been limited mostly to laboratory use. Chromite is burned at a high temperature and slowly cooled. It withstands very high temperatures and the action of slags, but is sensitive to sudden changes in temperature. It is especially useful on account of its chemical resistance and is used as a separating layer between magnesite and silica bricks in basic open hearth furnaces. Chromite is frequently used as a patching material. 10–20% added to fireclay and diaspor improve these very much. Silicon carbide is used without a binder or with clay as a binder. It has a very high heat conductivity and resists sudden temperature changes very well, but is attacked by ashes and slags containing Fe, S and Ca. It cannot be used in oxidizing atmospheres. It is used mostly in steam generating plants and for muffle furnaces, also as a patch. Zirconium oxide resists chemical attack, but is too expensive for industrial use. CEM(24)

The Slagging of Fire-Clay Bricks as Dependent on Flux Contents and Porosity. (Ueber die Abhängigkeit der Verschlackung von Schamottesteinen vom Flussmittelgehalt und der Porosität.) OTTO HEBESTREIT. Doctor's Thesis, Technical University, Aachen, 8 pages.

This investigation deals with those properties of fire bricks which influence the formation of slag and can be tested exactly, namely, chemical composition and porosity. The testing methods are described; the results are, briefly, the following: bricks of one part Al_2O_3 and 2 parts SiO_2, pure and containing fluxes, were made to form a slag with simply composed materials; no difference could be found in the behavior. The slagging is most pronounced with the oxides TiO_2, Fe_2O_3 and CaO; very little with Na_2O. The slagging is not proportional to the porosity except for absolutely identical bricks which differ only in porosity. The structure of the brick determines the formation of slag, especially the nature of the pores and their connections. Ha(24)

Some of the Newer Uses for Silicon Carbide. CHARLES MCMULLEN. *American Electrochemical Society, Preprint* 59–21, April 1931 meeting, 6 pages.

Important recent adaptations of silicon carbide are recorded and discussed. In recuperators cylindrical tubes are used. In the "Carboradiant" combustion chamber a mixture of air and fuel is injected into a silicon carbide box. The Thornhill-Anderson furnace has an arched overhead combustion chamber made of silicon carbide. Other applications include boiler furnace walls, heating elements, therapeutic lamps, resistors for radio equipment and lightning arresters. A tabulation of the physical properties of silicon carbide is appended. (24)

GASES IN METALS (25)

Removal of Gases from Aluminum Alloys. W. CLAUS. *Metallurgist*, Dec. 27, 1929, pages 190–191.

The methods for removing dissolved gases from molten Al alloys are described and the results given of experiments showing the effect of method developed by the author and Kalähne applied to Y-alloys and to 8% Cu alloy. Review of a paper in *Zeitschrift für Metallkunde*, Aug. 1929. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 389. (25)

The Combination of Alkali Metals with Nitrogen under the Influence of Electrical Discharges. (Ueber die Vereinigung von Alkalimetallen und Stickstoff unter dem Einflusse elektrischer Entladungen.) WILHELM MOLDENHAUER & H. MÖTTIG. *Berichte der deutschen Chemischen Gesellschaft*, Vol. 62B, Sept. 18, 1929, pages 1954–1959.

Contains 8 references. Alkali metals were introduced into a glass tube which was filled with N_2 gas to 25 mm. pressure and into which 2 Pt electrodes, about 7 cm. apart, had been fused. An electric current was discharged across the electrodes and when the pressure of N_2 fell to 1 mm. more N_2 was pumped in. This procedure was continued for many hours. Cs, Rb, K and Na form azides and Cs, Rb and K also form nitrides, which are formed by decomposition of the azides. Na does not form a nitride under these conditions and it has not been proved that a nitride exists. Li does not form an azide with N_2, but forms a small amount of nitride. CEM(25)

Nitrogen Segregation in Steel. (Stickstoffseigerung im Stahl.) H. DIERGARTEN & W. EILENDER. *Stahl und Eisen*, Vol. 51, Feb. 19, 1931, pages 231–232.

A brief survey of experiments of the above authors on segregations of nitrogen is given. The samples were taken from a low carbon basic open hearth ingot. The nitrogen contents in the center of the top and upper part of the ingot were found to be as much as 100% higher than in the outer parts of the ingot. The different behavior of steel of one melt may be due to the above segregations of nitrogen which are known to affect the properties. GN(25)

The Solubility of Oxygen in Solid Iron. (Ueber die Löslichkeit des Sauerstoffs im festen Eisen.) J. KEMPENS (Doktor-Ingenieur dissertation, Tech. Hochschule, Aachen), Feb. 1930, 30 pages.

The reaction $FeO + H_2 \rightleftarrows Fe + H_2O$ was studied from both directions. Heating iron in H_2O vapor $-H_2$ mixtures indicated that at 715° C., 0.11 ± 0.015% of oxygen was soluble in the iron, and at 800° C. 0.095 ± 0.010%. By heating Fe_2O_3 in a $H_2O - H_2$ mixture (28% H_2O), the oxide was reduced to an oxygen content of 0.146% at 715° C., and in a mixture with 32.5% H_2O, to one of 0.156% oxygen at 800° C. The methods of determination are described in detail. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 17. HWG(25)

Nitrogen in Technical Iron. Part IV. The Effect of Cold Work and Precipitation of Nitrogen on the Magnetic Properties of Technical Iron. (Zur Frage des Stickstoffs im technischen Eisen. IV. Das Zusammenwirken von Kaltverformung und Stickstoffausscheidung auf die magnetischen Eigenschaften des technischen Eisens.) W. KOESTER. *Archiv für Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 289–294; *Stahl und Eisen*, Vol. 51, Jan. 8, 1931, pages 37–38.

Report 167 of Materials Committee of the Verein deutscher Eisenhüttenleute. This investigation was carried on to determine in what manner the type of the segregation of nitrogen after various heat treatments affects the magnetic properties of cold worked steel, as well as to determine whether or not the sequence of these heat treatments has an effect. In the first group of tests, test bars of Thomas steel, suitable for the Koepsel magnetic testing apparatus, were stretched by 5% to 20% in a tensile testing machine and aged for 2 weeks at 100° C. In the second group of tests, the bars were first aged and then deformed. Aging causes a complete segregation of the nitrogen leading to a considerable increase of the coercive force. After these measurements had been made, the bars were gradually heated to study the effect of the renewed dissolving of the nitrogen, which is completed at 300° C. The coercive force increases with the degree of deformation in case the steel is present in annealed and slowly cooled state. Aging at 100° C. results in a further increase. This further increase decreases, however, with increasing deformation. The same results are obtained when the steel has first been aged and subsequently subjected to the deformation, i. e., the same dependence of the coercive force upon the degree of deformation is observed at the end of the deformation and heat treatment regardless of the sequence of the procedure. It is concluded that the specific effect of the precipitation of nitrogen upon the coercive force decreases with increasing degree of deformation. The particle size and the distribution of the segregated nitrogen has no bearing whatever on the coercive force, which is in agreement with the observation that the amount of precipitated nitrogen is independent of the degree of deformation. The hardness of the steel increases whether the nitrogen is in solid solution or precipitated. Finally, the importance of the above results for the investigation of the causes of mechanical aging is discussed. Maurer's observation is corroborated, that mechanical aging in carbon steels does not affect the magnetic behavior. The magnetic occurrences in the above Thomas steel between 100° and 300° C. are only due to nitrogen. GN(25)

Gases in Metals. C. J. SMITHELLS. *Metal Industry*, London, Vol. 38, Mar. 6, 1931, pages 261–264, 268.

Text of paper London Section of Institute of Metals, March 4, 1931. The solubility of gases in molten metals usually becomes greater at higher temperatures, and is generally much less in solid than in liquid metals. With H_2, Ni, Pb, Fe, Co, Cu and Pd form alloy systems, alkaline earths and alkali metals form hydrides, and Au, Ag, Be and Mg show practically no absorption. Comparatively few metals absorb nitrogen as a gas. The total volume of gas that can be abstracted from brass, Cu, Al or duralumin is of the same order as the volume of the metal, but Ni sometimes contains 100 times its own volume of gas. Removal of gases from metals involves melting in vacuum, or in the case of Al alloys slow pre-solidification with or without bubbling dry nitrogen or chlorine gas through metal, followed by rapid remelting to pouring temperatures. PRK(25)

Gas Removal and Grain Refinement in Aluminium Alloys. W. ROSENHAIN, J. D. GROGAN & T. H. SCHOFIELD. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 305–330.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. (25)

INSPECTION (26)

Rapid Estimation of the Nitrided Case. *Metal Progress*, Vol. 1, Sept. 1930, pages 46–47.

The Monotron, the Rockwell and the Brinell tests, if properly applied, have been found useful in checking the characteristics of the nitrided case by A. B. Kinzel and John J. Egan of the Union Carbide and Carbon Research Laboratories. J. Vilella, of the same laboratories has developed an etchant which gives a line of demarcation at the depth corresponding to an appreciable hardness change. The etchant is made as follows:

Dissolve in 100 ml. of water, 1.25 g. of $CuSO_4$, 2.5 g. of $CuCl_2$, 10 g. of $MgCl_2$, 2.0 ml. of conc. HCl, and dilute to 1000 ml. with 95% alcohol. WHK(26)

Use of X-Rays in the Aeronautical Industry. J. T. NORTON. *Aviation*, Vol. 28, June 28, 1930, pages 1261–1263.

Although the builders of aircraft have not employed X-ray methods to any extent, Professor Norton feels confident that they have a field of application in the materials and parts of which aircraft are made. Certain defects, such as blowholes in castings, inclusion of foreign materials, shrinkage and cracks are readily discovered by X-rays. The X-ray is also found to be extremely valuable in detecting flaws in welds and forgings. The use of this method of inspection has been retarded by the cost and the lack of portability of the equipment. The author asks that the cost be regarded in the light of insurance against failure. In view of the present experiments upon portable equipment, he sees a great future for radiography. (26)

Welding Inspection. R. KRAUS (Westinghouse Elec. & Mfg. Co.). *Preprint, American Society for Testing Materials*, Mar. 1931, 11 pages; *Electric Journal*, Vol. 28, Apr. 1931, pages 219–222.

Deals with visual inspection of welds. There are certain best methods of laying-on the metal for various types of welds. Watching the welders will show whether they are operating correctly. Fillet welds can be gaged for shape and size. Kerosine, immersion, soap and bubble and hot oil tests are briefly mentioned. Kraus states that it is still too early to decide whether non-destructive laboratory test methods such as X-rays, magnetic methods and stethoscopic examination, designed to eliminate the personal factor of visual inspection will find use in daily production. HWG + WHB(26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Chromium in Cast Iron Mixtures. T. F. JENNINGS. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Feb. 1931, pages 801–809.

For general purposes, the Cr content of cast iron should be under 1.0%. Cr increases the hardness, strength and wear resisting properties, does not affect shrinkage materially and lowers the fluidity of cast iron. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. CHL(27)

The Effect of Certain Elements Upon the Segregation of Cementite and its Relation to the Modification Process. J. H. ANDREW. *Royal Technical College Metallurgical Club Journal*, Glasgow, No 7, 1929–1930, pages 16–17.

Speculation upon the relation between the effect of 0.25% Mo in a 3% Ni steel, or of 0.60% Mn in a 0.22% C steel, in which the Mo or Mn is said to hinder free movement of carbides, preventing them from coalescing, and thus producing a fine sorbite, and that of Na in the modification of Al-Si alloys. HWG(27)

Nickel-Vanadium and Nickel-Molybdenum Cast Irons. (Étude sur les fontes au nickel-vanadium et au nickel-molybdene.) JEAN CHALLONSONNET. Second part. *Revue de Metallurgie*, Vol. 27, Dec. 1930, pages 654–671, 37 tables.

Experiments were conducted on 2 series of synthetic irons, free from the usual impurities and those containing Si and Mn in commercial amounts. To these Ni was added up to 2% and Mo up to 0.50% varying the Ni:Mo ratio from 1.6 to 8.75. In case of pure irons Mo addition has no influence on dilation point of cementite, raises Ac point to 725° from 660° and 665° respectively for 1 and 2% of Ni and opposes the graphitizing effect of Ni. No constituents of quenched character were found, though pearlite has a sorbite appearance. Mo pronouncedly increases thermal electromotive force of these alloys. In the second group (3.5 C, 1.3 Si, 0.40 Mn; 3.7 C, 2.5 Si, 0.50 Mn and 2.5 C, 2.5 Si, 0.50 Mn) Mo addition increased the hardness of irons without changing the amount of free cementite with exception of 2.5 C alloy. In gray irons Mo tends to nodulize the graphite, in Ni alloys it increases the dimensions of flakes but has no influence on the uniformity of their distribution. The effects of Ni and Mo combine in refining the structure of iron. In opposition to Si free alloys Ni here eliminates the whitening effect of Mo entirely, probably uniting its action with that of Si. Casting of the alloys into stepped molds showed that Mo does not increase their hardness by forming carbides and does not prevent the graphitizing effect of Ni though introducing a chilling effect with lower C content. The resistance to shearing is increased by its addition from 30 to 50%. JDG(27)

Effect of Nickel and Silicon on the Properties of Whiteheart Malleable Cast Iron (with Special Reference to "Thin-walled Malleable"). Part I. S. J. E. DANGERFIELD, F. JOHNSON & E. R. TAYLOR. *Carnegie Scholarship Memoirs, Iron & Steel Institute*, Vol. 19, 1930, pages 1–18.

10 references. Introduction covers briefly the history and properties of malleable iron. Back of published data on thin-walled malleable and lack of standard test bars of sizes applicable to such castings call for this study. Eight casts were made of the same base composition with varying Ni added, 0.0% to 3.6%. The high C content (3.35% total C) occurring in the base metal was not favorable to good properties as too long an anneal is required and graphitization is promoted. Graphitic C in annealed castings decreases with increased Ni but combined C is unaffected or slightly increased. Nineteen micrographs show the structures observed. Ni increases the fluidity, the tensile strength up to 2.5% Ni from which point it falls off rapidly, Ni does not impair the machining properties, and decreases the size of the temper C nodules up to 2.8% Ni. WLC(27)

On the Effect of Nickel and Manganese on the Properties of High Speed Steel. (Ueber den Einfluss von Nickel und Mangan auf die Eigenschaften von Schnelldrehstahl.) V. EHMCKE. *Krupp'sche Monatshefte*, Vol. 11, Dec. 1930, pages 295–315.

The article corresponds to the publication in *Archiv für Eisenhüttenwesen*, Vol. 4, July 1930, pages 23–35; abstracted in *Metals & Alloys*, Vol. 2, Jan. 1931, page 18. GN(27)

Studies on the Influence of Oxygen and Sulphur on Forging Qualities, Red Shortness and other Properties of Pure Iron. (Untersuchungen über den Einfluss von Sauerstoff und Schwefel auf die Schmiedbarkeit, Rotbrüchkeit und andere Eigenschaften des reinen Eisens.) ERIC W. FELL. *Disertation*, Düsseldorf, 1931 (Verlag Stahleisen m. b. h.). *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 393–400.

Thirty alloys were prepared with changing O and S contents. These were in 2 batches: the first with electrolytic iron as a base melted in a vacuum induction furnace, and the second with Armco iron as a base melted in an oil-fired furnace. These alloys contained up to 1.5% S and 0.144% O. Their forgeability was determined by an experienced smith, hammering out each ingot with a steam hammer into a small slab. The vacuum melted ingots forged better and at lower temperature than those melted in the oil-fired furnace. With 0.03% and more S and low O (0.023%) the ingots were brittle. With higher O content, over 0.05% O, and S contents of 0.01 to 0.02% the ingots were again brittle. The pure O melts (the iron melted in an atmosphere of O) all forged well. Some ingots, unforgeable at low temperatures, forged well at higher temperatures. All melts made from Armco iron were red short and as the S and O were deliberately increased became more so. Notch-impact values at temperatures up to 1080° C. were taken on the 30 samples. Vacuum-melted electrolytic Fe (0.03% O, 0.01 to 0.02% S) showed best toughness: 15.4 mkg./cm.^{2} at room temperature and 5.10 mkg./cm.^{2} at 1080°. Pieces with higher O contents showed very low impact values. All ingots melted in oil-fired furnace gave low impact values at high temperatures. The author gives Brinell hardness figures, discusses effect of O and S upon grain-size and depth of concentration. The effect of O upon red shortness appears to be one of lowering the safe S limit. RFM+GN(27)

Alloys in Steel Castings. F. A. MELMOTH. *Metallurgia*, Vol. 1, Dec. 1929, pages 73–74.

Increased severity of working conditions warrants the production of better steel castings. Such castings can be best produced by the addition of alloying elements such as Ni, Cr or Mo separately or in varied combinations. A table of values of tensile properties of plain and alloy castings indicate the superior properties of alloy castings. JLG(27)

Improvement in Saw Steels Attributed to Alloys. HENRY B. ALLEN (Henry Disston & Sons). *Steel*, Vol. 87, Nov. 6, 1930, page 54.

Abstract of paper read before Wood Industries Division of the American Society of Mechanical Engineers. After heat treatment, steel for the blade should have high elastic limit, good ductility, resistance to impact, resistance to fatigue cracking and uniformity. Ni, in proportions of 1.25%–3.5%, was first element added to plain C tool steel to improve quality. Several objections to this steel were its tendency toward a striated, crystalline structure and sluggishness in tempering. Cr was then tried and found to give high elastic limits, but at some sacrifice in ductility. The steel showed a tendency to check when considerably cold swaged. Cr, however, enhanced hardening power of Ni steels. Steel containing small amounts of Ni and Mo has particularly good ductility and toughness with high elastic limit. Best steel melting practice must be followed. MS(27)

The Advantages of Titanium Additions to Aluminum. (Ueber die Vorteile von Titanzusätzen zu Aluminium.) H. RÖHRIG. *Metallwirtschaft*, Vol. 10, Feb. 6, 1931, pages 105–111, 5 references.

It is difficult to alloy Ti with Al on account of the high melting point of Ti. The best method is to add TiO_2 to the Al ore and reduce the 2 together electrolytically. Ti added to Al in small amounts forms either $TiAl_4$ or $TiAl_3$, a brittle compound. Pure Al has a very coarse grained structure. By alloying with small amounts of Ti, 0.01% to 0.03%, the grain size is reduced considerably. This is illustrated by macrographs. Sheet Al, 1 mm. thick, containing from 0.01–0.19% Ti, was annealed at 500° C., stretched cold 2%, 5% and 10% and then annealed at 600°. The samples were etched in HCl-HF to show the recrystallization structure. With the higher Ti contents the grain size was smaller, but the difference was less noticeable with the 10% cold worked samples. With Ti free Al, recrystallization begins at 300°, with 0.19% Ti at 350°. The influence of these small quantities of Ti on the tensile strength and ductility is slight. The tensile strength of the samples containing Ti which were hard rolled, and those which were annealed at 350° C., was slightly higher and the ductility lower. For those annealed at 450° and 500° the reverse was the case. Corrosion tests were made by immersing samples for 1 hr. at 20° in 4 parts HNO_3, 4 parts H_2O and 1 part HCl. The loss in weight increased in the following order: Annealed at 500° (least), annealed at 450°, at 400°, at 350°, hard rolled (most). Samples containing Ti lost less weight than those without Ti. Those which were annealed during the hard rolling process lost more weight than those not annealed. CEM(27)

The Influence of Nickel and Nickel Chromium on the Properties of Malleable Iron. (Etude de l'influence du nickel et du nickel-chrome sur les proprietes de la fonte malleable.) LEON THIERY. *Revue de Metallurgie*, Vol. 28, Jan. 1931, pages 1–18; Feb. 1931, pages 61–77.

White irons prepared to contain 3% C, 0.4 Si, 0.10–0.20 Mn and 0.018–0.09 S were alloyed with 0.5, 1.4 and 2.5 Ni. They were tested together with the original base and an alloy produced by alloying it with 1.37 Ni and 0.34 Cr. Specimens were cast in sand but removed from it rapidly enough to produce chill. On plain carbon stock the dilation curves show the effect of quenching. The decomposition of cementite begins in them at 1100°. On repeated heating the cementite begins to decompose at A_c. The precipitation of graphite on the first heating can be seen under the microscope. With 0.5 Ni the dilation curves have the same appearance, at least on the first heating, but the cementite begins to decompose here at A_c. The presence of 1.4 Ni lowers by 100° the temperature of graphitization, reduces the temperature of γ-to α-transformation and lowers by 50° the A_r point. Addition of 2.5 Ni considerably increases the quenching action of the iron, reduces A_c below 700° and causes graphitization at 870°. The addition of 1.37 Ni and 0.34 Cr increases the cementite anomaly and raises the temperature of graphitization, reducing the tendency toward quenching by raising A_r point. Malleabilizing treatments showed that Ni helps to stabilize system by decomposing the cementite. It prevents changes on cooling and decreases the size of the constituents proportionally to its content. Chromium exerts an opposite action. One to two % Ni increases the tensile strength by about 30% and almost doubles the elongation. Toughness also increases, reaching 0.430 kg./m. for 1.5% nickel. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 18. JDG(27)

The Effect of the Addition of Various Elements to Cast Iron. A Review of the Literature. Parts I and II. E. E. MARBAKER. 13 pages. Privately printed by Whiting Corporation, Harvey, Illinois, 1930.

About 30 of the elements in the periodic table have actual or potential use in cast iron. The first of these 2 papers gives a brief general discussion, in which it is pointed out that a base iron of suitable quality in itself must be produced when addition of alloying elements is to be resorted to. The second paper deals with the influence of the individual alloying elements with some 65 references to the literature. The discussion of each element is very brief, but gives references to more detailed discussions in the literature. It is concluded that the possibility of improving cast iron by alloying is still unlimited in spite of the large amount of work already done. HWG(27)

The Effect of Silicon and Manganese on the Solidification of Iron-Carbon Alloys. (Der Einfluss des Siliziums und Mangans auf die Erstarrungsart von Eisen-Kohlenstoff-Legierungen.) O. v. KEIL & F. KOTYZA. *Archiv für Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 295–297; *Stahl und Eisen*, Vol. 51, Jan. 22, 1931, page 106.

Since there can be distinguished in cast iron, according to O. v. Keil, the difference between a stable graphite crystallization and a metastable crystallization with a subsequent decomposition, the effect of Si and Mn on Fe-C alloys with increasing C content was studied with a cooling velocity of 30° C./min. for both fields, the "white" solidification and the primary crystallization of graphite. It is indicated that within the cooling velocities chosen, silicon does not stabilize, but accelerates, the decomposition of cementite. By adding 0.3% Mn, the "white" field increases at the expense of the field of fine grain graphite. At the eutectic C concentration, the coarse leaf-shaped graphite appears. With increasing Mn content, the fine graphite disappears completely at 3.5% Mn. Evidently, at lower C concentrations, Mn favors the stability of the cementite but favors the stable phase at higher carbon contents. GN(27)

The Effect of Titanium on the Transformation Points of Steel. (Einfluss des Titans auf die Umwandlungspunkte des Stahles.) H. HOUGARDY. *Stahl und Eisen*, Vol. 51, Jan. 8, 1931, page 51.

An article by A. Michel and P. Bénazet in *Chimie Industrielle*, Vol. 23, 1923, pages 237–242 is reviewed. The effectof Ti on the α, γ-transformation was studied. The results confirm the results by Wever (*Mitteilungen Kaiser Wilhelm Institute für Eisenforschung*, Vol. 11, 1920, pages 193–223 and also *Stahl und Eisen*, Vol. 49, 1929, pages 1378–1379). The γ-field is closed at even relatively low Ti contents. GN(27)

The Effect of Phosphorus on the Strength of Admiralty Gun-Metal. H. C. DEWS. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 255–277.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 857. (27)

Characteristics of Modern Alloy Chilled Iron Rolls. W. H. MELANY. *Rolling Mill Journal*, Vol. 4, Dec. 1930, pages 669–672.

Cr is one of the common alloying elements used to promote the formation of combined C, thus producing a harder and closer grained surface on the roll. Such rolls are necessary for hot rolling full finished sheets. Softer rolls with a greater amount of graphite C having a reduced grain size are produced by adding Mo or Ni. A type known as "grain roll" in which the combined C is greatly in excess of the graphitic C is generally produced by adding Cr and Mo. In this type, the chilled surface has lost its crystalline structure and has a grain formation, and the apparent chilling effect reaches to a greater depth than usual. The surface is much softer than in the ordinary chilled roll. It offers great resistance to fire cracking, and considerable resistance to abrasion, but is easily machined. It is being applied to the rolling of small sections and to rod-mill work. A Cr-Ni iron roll has been developed but has not met with favor due to the difficulty of machining. The surface is not as hard as was thought at first but it is exceedingly tough. It is very resistant to wear. MS(27)

Addition of Nickel and Chromium for Cast Iron Cylinders of Automobile Engines. (Nickel- und Chromzusatz für Gusseisen-Zylinder von Automobilmotoren.) MAHL. *Automobiltechnische Zeitschrift*, Vol. 33, Feb. 10, 1931, pages 97–99.

Additions of the named elements of gray iron, which is generally used in the manufacture of automobiles, have the following effects: (1) Si reduces the contents of free C, prevents quick cooling and softens the structure; (2) Ni reduces the contents of free C, but hardens the structure; (3) Cr stabilizes free C, increases the cooling and hardens the structure. The most practical values were 1.5% Ni together with 0.4% Cr in American practice, while others use 1.5% Ni with 0.3% Cr or 1% Ni with 0.2% Cr. Ha(27)

Effect of Composition and Structure on the Wear of Cast Iron. (Weitere Untersuchungen ueber den Einfluss der Zusammensetzung und des Gefügeaufbaus auf den Verschleiss von Gusseisen.) T. KLINGENSTEIN (Esslingen Maschinenfabrik). *Mitteilungen aus den Forschungsanstalten, Gutehoffnungshütte Konzern*, Vol. 1, April 19, 1931, pages 80–92.

In order to study the wear of one cast iron upon another, as in the case of piston and cylinder, a flat surface of one cast iron specimen 3 × 3 × 1 cm. is subjected to wear by a flat-ended rotating cylinder of another cast iron specimen 1 cm. diameter, moving at 325 r.p.m. under a pressure of 4 kg. (24 kg./cm.^{2}) as if the rotating cylinder were a drill. The total wear is the sum of the weight losses of both the flat and the cylindrical specimens. Each test was run 10 minutes without lubrication. The iron was cast upright into plates 1.3 × 9 × 15 cm. The effects of pressure and of speed were first studied. Wear increased linearly with increase of peripheral speed, and decreased hyperbolically with decrease in pressure. Individual determinations agreed within 10%. Working on all possible combinations among 3 irons cast both in green and dry sand and containing 3.30% total C 1.75% Si, 1% Mn, 0.40% P, 0.05 to 0.10% S; 3.30%, 1.50%, 1%, 0.40%, 0.10%; and 3.50%, 2.25%, 0.75%, 0.33%, 0.075%, respectively, with Brinell's of about 230 for the first 2 and 185 for the last, it was found that the total wear was least when the 2 specimens had the same hardness, rose as the difference in hardness increased, and that it was somewhat less when the rotating specimen was harder than the stationary one than when these conditions were reversed. These conclusions were checked on a 3.25% total C, 1.15% Si iron of 243 Brinell, working against itself and against the other specimens, but the curves for the softer irons were concave upward when wear loss is plotted vertically, and difference in hardness horizontally, while when the 243 Brinell iron was used, they were convex upward. For a given hardness difference the wear was less the harder the irons used. This is discussed in relation to pistons, piston rings and cylinders, and it is concluded that they should all be made of the same iron, but if not, the moving part should be the harder. Better surface structure to resist wear is obtained at 220 Brinell than at lower hardness. The effect of temperature upon wear up to 250° C. is not appreciable, save for a slight increase in wear with rising temperature with one iron containing 1.90% P. The influence of alloying elements was studied and curves for wear as cast, and after annealing 3 hours at 900° C. are given. In both cases increase of Si increased wear. Ni had no effect one way or the other, and increase of Mn had practically no effect. In the as-cast state P notably decreased wear, but in the annealed state it did not until more than 1¼% was present. With as-cast specimens Cr had no effect until more than ¼% was present, but in annealed specimens it showed its effect in smaller quantities. The greatest decrease in wear was found when Cr was added. Since Ni alone has no effect, it is the Cr in Ni-Cr irons that produces wear-resistance. The curves showing the effect of alloying elements on wear-resistance are plotted from a small number of compositions. HWG(27)

Vanadium Additions Improve Steel. N. PETINOT (Vanadium Corp. of America). *Steel*, Vol. 87, Aug. 21, 1930, pages 43–45, 48; Aug. 28, 1930, pages 47–49; Sept. 4, 1930, pages 56–57, 60.

Paper presented to the Sixth International Congress of Mining, Metallurgy and Applied Geology, Liege, June 22–28, 1930. French translation is credited to S. B. Saklatwalla, J. Strauss, H. Chandler and G. Morris. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 19. MS(27)

INSTRUMENTS & CONTROLLERS (28)

A Precision Time Switch for X-Ray Tube Circuits. WILLIAM K. KEARSLEY. *General Electric Review*, Vol. 34, Feb. 1931, pages 127–128.

The modern mechanical type of time switch for radiographic outfits consists of a small motor with a gear train and small contacts serving to close and open a circuit that in turn operates a switching device in the supply circuit. A new form of timer operating on this principle is illustrated. Outstanding features are: (1) high precision; (2) ease of setting; and (3) quiet operation. Each feature is discussed. WHB(28)

Measuring, Signaling and Control Installations in the Blast-Furnace Plant Essen-Borbeck of Fried. Krupp. (Die Mess-, Signal- und Regelanlagen des Hochofenwerks Essen-Borbeck der Firma Fried. Krupp Aktiengesell schaft.) P. OSTWALD & W. LIESEGANG. *Siemens-Zeitschrift*, Vol. 11, Feb. 1931, pages 49–56.

Detailed description of location and kind of instruments used in this new plant for indicating, recording and measuring of gases and air in the operation of two blast-furnaces of 600 tons per day; there are 31 places where instruments are placed which are all wired for remote reading in the control observation room. Ha(28)

Radiation Pyrometry. E. L. FIDGE (Workingmen's College, Melbourne). *Chemical Engineering & Mining Review*, Vol. 23, Feb. 5, 1931, pages 189–941, 7 references.

Temperature measurement instruments are placed in 2 general groups which primarily depend for operation on the transfer of heat by conduction and radiation, respectively. The first type does not lend itself to the determination of temperature of a given inaccessible place nor for the temperature determinations of objects of small mass. There are 2 main types of radiation pyrometers: The total radiation pyrometer which uses the whole spectrum of radiation from a hot body, and the spectral radiation or optical pyrometer operating on a selected part of the total spectrum. The latter type may be further divided into: (1) the disappearing filament (Morse type); and (2) the polarization pyrometer (Wanner type). Characteristics of the various types are noted and certain mathematical derivations made. WHB(28)

Photoelectric Control for Soaking-Pit Covers. R. M. BAYLE. *Electrical World*, Vol. 97, Feb. 28, 1931, page 409.

A Middle West plant has a soaking pit control which makes use of a light-sensitive relay as the initiating source. The moving crane carries only a foot-operated push button and a light box mounted on the end of the crane for each soaking pit spanned by the crane. The layout consists of 2 soaking pit cranes operating on a common runway and each spanning 2 pits. Preparatory to opening a cover or during the operation the crane may be shifted 5 ft. on either side of the center line and the operating lamp box will be opposite the light relay for that cover. To open the cover a single short flash of the lamps in the light box is all that is necessary. The circuit is self-maintaining. A simple transfer circuit permits the light ray to be alternately effective to open or close the pit cover. The light-sensitive cells respond only to concentrated light above the room illumination, leaving no danger of false operation. WHB(28)

Recording Dust Concentration Meter for Blast Furnace Gas. A. W. SIMON (Tennessee Coal, Iron & Railroad Co.). *Blast Furnace & Steel Plant*, Vol. 19, Nov 1930, pages 1686–1689, 1700.

Paper read before the American Iron and Steel Institute. MS(28)

A Vacuum Tube Time Switch. WILLIAM K. KEARSLEY. *General Electric Review*, Vol. 34, Feb. 1931, page 128–129.

A photograph of a laboratory set-up of the apparatus comprising the vacuum-tube time switch is shown, also a diagram of connections of the time switch coupled to an X-ray generator. Two thyratron tubes and a glow tube are used together with a condenser and 4 resistances. The only moving part is a 4-blade double-throw control switch. The advantages of this type of timer are its mechanical sturdiness, precision and reliability. WHB(28)

Lubricants and Bearing Test Machine. E. S. GLAUCH (Jos. Dixon Crucible Co.). *Iron & Steel Engineer*, Vol. 8, Mar. 1931, page 129.

An illustrated description of a specially designed test machine that takes a load up to 37,300 lbs. on the bearings on which either lubricant or bearing is being tested. Speed can be varied and loads applied to suit. WHB(28)

Contact Pyrometers. (Anlege-Pyrometer.) W. CLAUS & R. HASE. *Zeitschrift für Metallkunde*, Vol. 23, April 1931, pages 120–123.

The necessity of temperature measurements on the surface of solid bodies is emphasized, theoretical conclusions are drawn, and the accomplishment of those measurements and the necessary instruments are considered. EF(28)

Temperature Measurement of Molten Cast-Iron. (Temperaturmessungen an flüssigem Gusseisen.) J. MOELLER. *Die Messtechnik*, Vol. 7, Apr. 1931, pages 93–96.

After a discussion of the importance of the temperature measurement of the liquid cast-iron the three principal measuring methods are described and compared: thermoelectrical pyrometer, total radiation pyrometer, partial radiation pyrometer; the latter type is considered to be the most practical. As an example for the latter the "Pyropto" of Hartmann & Braun is described. From measurements with an instrument of the latter type the following emission coefficients of iron have been found: iron, solid, polished, 0.45; iron, liquid, bright, 0.40; iron, solid, in air (below 137° C.) 0.90; iron oxide 0.90; lead bath (slag) about 1.0; salt baths, about 0.80. These figures give the difference between the radiation of a black body and the not completely black body. A diagram is given from which the corrections for temperatures up to 2000° C. can be taken directly. Ha(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The Tensile Properties of Alloy Steels at Elevated Temperatures as Determined by the "Short-Time" Method. WILLIAM KAHLBAUM, R. L. DOWDELL & W. A. TUCKER. *Bureau of Standards Journal of Research*, Vol. 6, Feb. 1931, pages 199–218.

By means of "short-time" tension tests a series of alloy steels has been tested at different elevated temperatures. The proportional limit was determined in each case. The materials tested were a plain carbon steel and commercial alloys of chromium, vanadium and iron with and without additions of tungsten, silicon or aluminum; also chromium-tungsten, nickel-molybdenum and several austenitic steels with and without tungsten. Metallographic study revealed very little intercrystalline weakness and no marked or significant change in structure resulting from the high temperature tests. The addition of tungsten increases the "structural stability" of the austenitic alloys. Hardness was determined as a further indication of tempering which might have occurred during the heating. A comparison of "short-time" test and "flow test" for pearlitic and austenitic steel is included. (29)

Mechanical Properties of High-Speed Steel at Elevated Temperatures. A. R. PAGE (Birmingham Central Labs.). *Metallurgia*, Vol. 1, Apr. 1930, pages 239–241.

Tensile tests at temperatures up to 950° C. were made on annealed, underhardened, correctly hardened and overhardened 14% W high-speed steel. The annealed steel began to soften rapidly at about 500° C. At 900° or 950° C. there was a drop in elongation and reduction in area that indicated a brittle range. The strength of the underhardened steel was high, 136 tons/in.^{2} at room temperature. It fell gradually to 500° C. and then rapidly. In the correctly hardened steel the strength did not fall rapidly until 600° C. was reached, and at 650° C. the strength was 70 tons/in.^{2} In the overhardened steel the strength was low at all temperatures, and it appeared to have no ductility. Hardness tests were made on the steel in the several conditions. The correctly hardened steel after having been tempered at 600° C. did not decrease in hardness after holding for 30 min. at 650° C. JLG(29)

Some Experiments on the Impact Hardness of High-Speed Steel at Elevated Temperatures. A. R. PAGE. *Metallurgia*, Vol. 3, Jan. 1931, pages 85–86.

Impact hardness values were obtained at temperatures up to 800° C. In hardened untempered steel a minimum hardness occurs at 400° C., and a maximum at 550° C., above which there was a rapid softening. The behavior of the underhardened specimen is similar except that the maximum occurs at 500° C. In a tempered specimen there is a slight decrease in hardness up to about 600° C., then a rapid decrease. JLG(29)

Some Long-Time Tension Tests of Steels at Elevated Temperatures. J. J. KANTER & L. W. SPRING. *Proceedings American Society for Testing Materials*, Vol. 30, Part 1, 1930, pages 110–132.

See *Metals & Alloys*, Vol. 2, Feb. 1931, page 50. HWG(29)

The Strength of Gray Cast Iron at Elevated Temperatures. J. W. DONALDSON. *Journal West Scotland Iron & Steel Institute*, Vol. 38, Nov. 1930, pages 11–20.

Cast irons comprising 2 plain irons containing 0.65% and 1.48% Si respectively, alloy irons containing 2.43% Mn, 0.40% Cr, 0.75% Ni, 0.12% V, 0.48% W, and 0.61% Cr, 0.30% Ni, 0.02% C, respectively, were investigated to determine (1) the temperature-stress curves of a series of plain and alloy irons, (2) the influence of previous heat treatment on the temperature-stress curves, and (3) the effect of low Si and various alloy additions on the strength of cast Fe at elevated temperatures both as cast and after heat treatment. (29)

Creep of Metals at Elevated Temperatures. P. G. MCVETTY. *Mechanical Engineering*, Vol. 53, Mar. 1931, pages 197–200; *Iron Age*, Vol. 127, Mar. 12, 1931, pages 868–870, 919.

In the past 6 or 7 years the term "creep" has become familiar to all engineers. In its simplest form we may think of a vertical cylindrical rod supported at the top, carrying a constant load at the bottom, and heated to some constant high temperature over a definite portion of its length. If means are provided for measuring with great accuracy any change in length of the section in which stress and temperature are maintained constant, data may be obtained from which the usual creep curve can be plotted. The author discussed the probable nature of creep phenomena, the various forms of creep curves, the metallurgical aspects, the significance of creep to the designer of parts to withstand high temperatures, and concludes that the collection of reliable creep data for the numerous metals and alloys now available will require many years. In the meantime it is probable that extensive service applications will be made without having complete data on creep phenomena. These are, in themselves, the best kind of tests if accurate records are kept, and it is hoped that all such data will be carefully preserved and published. MFB(29)

The Strength of Steels at High Temperatures. H. A. DICKIE. *Royal Technical College Metallurgical Club Journal*, Glasgow, No. 7, 1929–1930, pages 32–37, 10 references.
Brief general discussion. HWG(29)

Progress in the Manufacture of Alloy Steels. S. J. HEWITT. *The Industrial Chemist*, Vol. 7, Jan. 1931, pages 19–20.
A brief review in which considerable attention is given to a paper read before the Iron and Steel Institute by Dr. W. H. Hatfield on "Permanence of Dimensions under Stress at Elevated Temperatures" giving the results of tests carried out on a large number of alloy steels in common use, to determine the safe stress at temperatures between 300° and 700° C. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 798. MPB(29)

Report on Hot-Hardness Characteristics of Some Modern Tool Steels and Alloys. E. G. HERBERT. *Proceedings Institution of Mechanical Engineers*, No. 3, May 1930, pages 681–692.
Report of the Cutting Tools Research Committee. Presents a chart showing the hardness of "Widia," nitrated, high speed, high carbon steel superhardened high speed steel, S. O. B. V. steel superhardened by cloudburst, S. O. B. V. normally hardened. Studies were made of the depth of hardening and the effect of superhardening by cloudburst and by pendulum work hardening. RHP(29)

Physical Properties and Behavior of Cast Iron at High Temperatures and at Various Conditions of Stress. (Festigkeitseigenschaften und Verhalten von Gusseisen in der Wärme und bei verschiedenen Spannungszuständen.) R. MAILÄNDER. *Stahl und Eisen*, Vol. 51, Jan. 22, 1931, pages 106–108.
The author reviews 3 Swiss publications on the above subject, E. Dübi, Discussion Report 37, 1928, pages 7–18, Eidgenössiche Materialprüfungsanstalt, Technische Hochschule Zürich; E. Honegger, Discussion Report 37, 1928, pages 21–36, Eidgenössische Materialprüfungsanstalt, Technische Hochschule Zürich, and M. Ros & A. Eichinger, Discussion Report 37, 1928, pages 39–64, Eidgenössische Materialprüfungsanstalt, Technische Hochschule Zürich. GN(29)

Effects on Cast Iron of Prolonged Heating at 800–1100° Fahrenheit. R. S. MACPHERRAN & REXFORD H. KRUEGER. *Transactions & Bulletin American Foundrymen's Association*. Vol. 2, Feb. 1931, pages 826–864.
Various types of cast iron were heated for 500 hours at 800° to 1100° F. and were afterward tested for chemical composition, strength, Brinell hardness and deflection. High Si and Ni accelerates decomposition of pearlite. The action is slower with low Si, low C and Cr. Tables and graphs of data are given. See also *Metals & Alloys*, Vol. 2, June 1931, page 122. CHL(29)

LEACHING (30)

The Action of Sulfur Dioxide on Manganese Oxides at Elevated Temperatures. C. W. DAVIS. *Bureau of Mines Report of Investigations* 3033, Oct. 1930, 16 pages.
There is little advantage in roasting Mn minerals in a SO_2 atmosphere since dissolution in SO_2 solutions is so satisfactory. The rate of manganese sulphate decomposition to oxides after evaporation increases with temperature. At 950° complete conversion takes place in 30 minutes. If the air above roasting zinc sulphide ore containing manganese contains 5% SO_2, in 4 hours manganous oxide, manganese sulphate and 40% manganese dioxide will be formed. The manganese sulphate can be recovered by a water leach, the manganous oxide and manganese dioxide by sulphuric acid. Since the higher oxides of Mn are often added to solutions of Zn salts before electrolysis to oxidize the Fe salts, the manganese dioxide would be doubly useful. AHE(30)

Note on the Extraction of Copper from Oxidized Ores by Cyanide Solution. E. T. DUNSTAN. *Journal Chemical, Metallurgical & Mining Society of South Africa*, Vol. 31, Jan. 1931, pages 190–194.
Cyanide extraction of a malachite ore from Katanga containing 9.36% Cu resulted in high cyanide consumption. Regeneration electrolytically was impossible. Details are given. AHE(30)

Electrolytic Copper from Copper Concentrate. WM. E. GREENAWALT. *Engineering & Mining Journal*, Vol. 129, Mar. 1930, pages 241–244.
Leaching and electrolysis can solve every problem on almost all copper concentrates, but certain fundamentals must be observed to compete with or to supplant smelting: (1) roasting to get a satisfactory extraction by leaching, comparable with slag losses in smelting; (2) proper control of ferric ion in electrodeposition of the copper from copper solutions containing salts of iron; (3) the recovery of lead and the precious metals, if contained in appreciable amounts, in the copper concentrate. Roasting, leaching and electrolysis are discussed, and a revised flow sheet is shown. WHB(30)

Extraction of Tantalum and Columbium from Their Ores. COLIN G. FINK & LESLIE G. JENNESS (Columbia University). *Technical Publication* No. 379, *American Institute of Mining and Metallurgical Engineers*, 1931, 18 pages.
Describes methods developed for extraction. Tantalum and columbium occur together in tantalite and columbite ores. These 2 elements can be extracted by leaching with HF, but the addition of oxalic acid increases the efficiency of the HF solution. The HF can be produced from CaF_2 and H_2SO_4. The method appears to be commercially practicable. Methods for extracting the metallic salts from the leaching solution are given. 5 references. JLG(30)

Leaching Copper Ores: Advantages of Wet-Charging. JOHN D. SULLIVAN & ALFRED P. TOWNE. *Bureau of Mines Report of Investigations* 3050, Feb. 1931, 26 pages.
Charging the ore into the leaching vat in the wet condition increases the extraction of Cu. Virtually identical extraction was obtained by upward and downward percolation when the solutions were not continuously circulated. In the latter case, extraction was greater on downward percolation. Virtually identical extraction resulted from flood and trickle leaching when the ore was wet-charged. With dry charged ore, extraction was greater from +100-mesh ore than from unsized material containing fines; there was no difference when the ore was wet charged. AHE(30)

Oxygen as an Aid in the Dissolution of Silver by Cyanide from Various Silver Minerals. E. S. LEAVER, J. A. WOOLF & N. K. KARCHMER. *Bureau of Mines Report of Investigations* 3064, Jan. 1931, 15 pages.
Cerargyrite is completely soluble in cold cyanide solution in 8 hours. Practically all the Ag in stetefeldtite is dissolved by cold cyanide in 24 hours. Argentite, polybasite, stephanite and pyrargyrite are slowly soluble under the usual conditions of cyanidation. Their rate of dissolution is materially increased by supplying additional oxygen. Proustite, similar in composition, did not show any material increase in extraction by use of oxygen. By a preliminary low-temperature roast, an extreme case of oxidation, the resulting calcines yield an extraction of 90% of the Ag by cyanidation. Tetrahedrite is the most refractory mineral tested. Direct cyanidation, even with excess oxygen, gave less than 25% extraction. Preliminary roasting increased this figure. In general, oxygen is an aid in the treatment of Ag minerals by cyanidation. Warm solution also increases the dissolution rate. Low-temperature roasting is usually effective if the preceding fail. Usually 72 hours or more are required for maximum dissolution of Ag by cyanidation. AHE(30)

REDUCTION METALLURGY (31)

Retreatment of Mother Lode (California) Carbonaceous Slime Tailing. EDMUND S. LEAVER & JESSE A. WOOLF. *Technical Paper* 481, *United States Bureau of Mines*, 1930, 20 pages.
Gives results of Bureau of Mines experiments with slimes and tailings from the Mother Lode district. The present method of recovering the free Au by amalgamation could be improved on by installing a modern flotation department, which would soon pay for itself. AHE(31)

Copper and Zinc in Cyanidation Sulphide-Acid Precipitation. EDMUND S. LEAVER & JESSE A. WOOLF. *Bureau of Mines Technical Paper* 494, 1931, 63 pages.
All of the common Cu minerals except chrysocolla and chalcopyrite are sufficiently soluble in cyanide solution to cause excessive reagent loss (2 to 3 lbs. NaCN/lb. copper) unless the cyanide combined with the Cu is regenerated. The Na_2S-H_2SO_4 method regenerates an average of 80% of the cyanide from solutions used to treat precious metal ores containing up to 0.5% cyanide soluble Cu. Solutions used to treat cuprite or metallic Cu give large regeneration. The more complex the Cu mineral treated, the less cyanide will be regenerated from the resulting solution. The more nearly all the cyanide is combined with Cu and the less is uncombined (free) cyanide, the greater will be the regeneration. The amount of Na_2S used varies with the amount of metals precipitated. The acid consumption varies with the strength of the original solution in both cyanide and lime. The Ag may be precipitated separately from the Cu before the solution is acidified. The Cu sulphide must be removed from the acid solution as it redissolves in alkaline cyanide solution. Only a small amount of Au is precipitated by the Na_2S-H_2SO_4, most must be removed by Zn as usual. Cu in cyanide solution up to 10 lbs./ton does not diminish the activity of the solution as a solvent for Au and Ag if the requisite free cyanide is present. The double Na-Cu cyanide solution, in the absence of free cyanide, is only a weak solvent for the precious metals and is more effective for Au than Ag. Smithsonite, hydrozincite, zincite and calamine are soluble enough under the usual conditions of cyanidation to cause rapid accumulation of Zn in the solution unless special precautions are taken to remove it. Willemite, sphalerite and franklinite are dissolved more slowly. From 1.5 to 4.0 lbs. NaCN is needed per lb. Zn dissolved. The various Zn cyanide compounds are only weak solvents for the precious metals, even if Ag nitrate titration shows free cyanide. Addition of excess lime or caustic soda improves extraction by liberating free cyanide from the double salt. If most of the cyanide present in a solution is combined with Zn, more free cyanide must be added to this solution than to a fresh solution for the two to have equal activity as solvents. Na_2S-H_2SO_4 treatment will remove Zn and regenerate cyanide. When ores containing soluble Zn minerals are treated, the solution must contain excess free cyanide or the dissolution of Zn will decrease Ag extraction. The Welch method was thoroughly tried and seems to apply only to Au ores or to Au-Ag ores containing not over 0.1% of cyanide-soluble Cu and in which Ag occurs as a haloid mineral. AHE(31)

The Reduction of Iron Ores in Smelting Furnaces and the Structure of the Cast Product. J. E. FLETCHER. *Iron & Steel Industry & British Foundryman*, Vol. 3, July 1930, pages 295–298; Aug. 1930, pages 335–338.
A new view of alloying reactions in the blast-furnace is advanced. Molten pig iron is a mixture of carburized sponge iron and an alloy of iron with Si, Mn and P. The author concludes that the reactions occur at the slag-metal interface. CHL(31)

Burdening the Blast Furnace. ROY P. HUDSON. *Rolling Mill Journal*, Vol. 4, Sept. 1930, pages 485–488; Nov. 1930, pages 601–604.
Describes methods for the calculation of blast-furnace burdens. Intended primarily for the furnaceman. MS(31)

Reduction of Zinc Oxide by Methane or Natural Gas. H. A. DOERNER. *Report of Investigations* No. 3091, United States Bureau of Mines, Apr. 1931, 14 pages.
$ZnO + CH_4 = Zn(gas) + CO + 2H_2$ is nearly complete when equilibrium is attained (0 gas velocity) at about 927° C. The reaction rate increases with temperature, but CO_2 formation and subsequent reoxidation of Zn also increase. Temperatures should therefore be kept below 1000° C. Crude natural gas gives approximately the same results as methane, the higher reducing power of the homologues of methane being compensated by their greater tendency toward thermal decomposition. A preliminary treatment to remove (sulphate) sulphur is advantageous. This may be accomplished by heating the calcine at 800° C. in an atmosphere of natural gas or the gaseous products from the Zn condenser. Cd may also be eliminated by this step. In the temperature range 975–1000° C. the rate of Zn distillation compares favorably with that obtained from retorts by standard practice, the metal produced is of exceptional purity and no appreciable amount of blue powder is formed. The special requirements of a furnace for commercial reduction of Zn by natural gas are (1) a retort and condensing system as nearly gas-tight as possible, (2) continuous feed and discharge of ore at a slow rate (time of residence, about 34 hours), (3) continuous counterflow of gas at a low velocity (time of contact, about 1 minute), (4) retorts having a large capacity, and (5) pretreatment of the ore in a separate retort at 800° C. or lower with gas from the Zn metal condenser. Under these conditions Cd and S are volatilized and Fe is reduced to metal. The length of the retort is limited by the resistance of the ore to the flow of gas and by the necessity to prevent transportation of dust incident to the higher gas velocity required by long retorts if the time of contact is constant. The smallest dimension of the retort will be limited by the requirements of heat transfer. The relatively low operating temperature and the presence of the excellent thermal conductor, H_2, facilitate the flow of heat and permit large units to be used. AHE(31)

Graphical Carbon Balance of the Blast Furnace. T. J. ESS (Republic Steel Corp.). *Iron & Steel Engineer*, Vol. 8, Apr. 1931, pages 173–176.
Charts developed to facilitate a check on gas production, blast volume and furnace practice are shown and the application is explained in determining the carbon balance. The balance worked through analytically agrees substantially within slide rule limits. WHB(31)

Smelting Secondary Aluminum and Aluminum Alloys. ROBERT J. ANDERSON. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, pages 555–556.
This installment being part 10 of a series started in 1925. Describes furnace tools used in secondary practice such as pig tongs, spout plug, rabbling hoe, skimmers, etc. VSP(31)

Machine Cast Pig Iron Has Greater Uniformity. F. B. RIGGAN & L. S. MORGAN. *Steel*, Vol. 87, Dec. 18, 1930, pages 60, 63.
An important improvement in southern pig-iron has been the installation of pig casting-machines. Pigs, however, broke easily. This difficulty has been eliminated by spraying the hot empty molds with a heavy coating of CaO and NaCl and allowing the molten Fe in the molds to cool in transit to about 1600° F. before subjecting it to H_2O spray. The coating effects a slight desulphurization. The newer pig-iron is held for some time in large mixer-type ladles, and thus has an opportunity to cleanse itself. Slag is removed by 3 skimming operations, before the metal enters the traveling molds. Pigs have a smooth, clean surface and uniform fracture as well as being no longer easily broken. MS(31)

WANTED

HALF-TON ELECTRIC MELTING FURNACE, COMPLETE. GIVE DESCRIPTION AND PRICE IN FIRST LETTER. BOX F, Metal & Alloys, 3619 Forbes St., Pittsburgh, Pa.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

801 **X-Ray Inspection.**—The Claud S. Gordon Co., 708 West Madison St., Chicago, Ill., is prepared to X-ray steel, iron, brick, clay, wood and any metal up to a thickness of $3^1/_2$ inches for steel and 8 to 9 inches for aluminum. Such items as patterns, tools, dies, castings, raw materials, etc., may be examined. This service is described in a leaflet, "Secrets of Metal," recently issued by them.

802 **A-C. Welder.**—A leaflet, No. 20522, entitled, "Flex Arc A-C Welder" has been announced by the Westinghouse Electric & Manufacturing Co. This unique welder meets the great demand for the economical arc welding of such gage material as encountered in the manufacture of metal furniture sheet steel cabinets, air-craft fabrication, job and garage repair work and erection of ventilating systems and materials handling equipment of many kinds.

803 **Melting Furnaces.**—Catalog No. 6 of the Bellevue Industrial Furnace Co., 2971 Bellevue Ave., Detroit, Mich., lists and illustrates various sizes of their brass and aluminum melting and crucible heating furnaces and accessories designed to supply standard equipment for melting non-ferrous metals.

804 **pH Comparator.**—A new Nickel pH Comparator is discussed in a leaflet sent out by the Kocour Co., 4724 South Turner Ave., Chicago, Ill. The set is described and detailed instructions for its use are given. The same company also advertises analytical sets for chloride in nickel solutions and for determining sulphuric acid and copper sulphate in acid copper solutions.

805 **Cutout.**—The Hevi-Duty Automatic Excess Temperature Cutout is a protective unit for furnaces. This is intended to replace the excess temperature fuse or link in the furnace control circuit. It is discussed in a sheet sent out by the Hevi-Duty Electric Company, Milwaukee, Wis.

806 **Electric Furnaces.**—The Hevi Duty Electric Co., Milwaukee, Wis. has issued several bulletins on their different types of electric furnaces. Bulletin 430 is devoted to Box Type Electric Furnaces. Bulletin 230 is on Conveyor Furnaces. Bulletin 530 discusses the Rotary Retort Furnace and Bulletin 930 describes the Pot Type Furnace.

807 **Piping and Valves.**—Bulletin No. 44 of the Semet-Solvay Engineering Corp., 40 Rector St., New York, N. Y., covers their piping and valves. It contains suggestions for efficient planning of new piping and diagrams of operating arrangements for gate valves, as well as tables of standards for the different pipe sizes.

808 **Alloy Steels.**—According to Bulletin No. 31-2 sent out by the Wehr Steel Co., Milwaukee, Wis., their engineers will obtain alloy steel castings to fill a particular analysis and will heat treat them to any specifications. The physical analyses of the Wehr steels are given.

809 **Blast-gates.**—The W. S. Rockwell Co., 50 Church St., New York, N. Y., has sent out a leaflet, No. 303, describing their air-tight blast-gates. The illustrations show different types of control and several tables give their dimensions. Leaflet No. 306 gives a brief description of their non-oxidizing annealing furnace.

810 **Automatic Reversal of Open-hearth Furnace.**—Copies of a new bulletin, No. 841, explaining automatic reversal of open-hearth furnaces and the improvements it can effect in open-hearth performance, are available through the Leeds & Northrup Company of Philadelphia. Every phase of L & N Automatic Reversal is covered in this bulletin—how reversals are made automatically—what the system is—how it operates—and its advantages.

811 **Refractory Materials.**—Corundite Refractories, Inc., Massillon, Ohio, have compiled a catalog containing valuable information in connection with the use of standardized clay fire brick and super-refractories. The last half of the catalog contains useful tables showing the number of shapes of brick required for different size furnaces.

812 **Grits & Grinds.**—An attractive new make-up is a feature of the May issue of this publication of the Norton Company, Worcester, Mass. The subject to which it is devoted is "Putting the Shop in Order Increases Plant Capacity." It includes a number of interesting illustrations and diagrams.

813 **Potentiometer Pyrometer.**—An attractive 12-page folder has just been issued by the Brown Instrument Co., Philadelphia, Pa., showing in tabloid form the principal features of their new potentiometer. Extreme accuracy and ruggedness is claimed for this new instrument and the folder shows many of the constructional features substantiating this claim. The folder is arranged for easy reading and gives a good idea of the instrument illustrated.

814 **Hardometer.**—The Firth Hardometer is now handled in the United States by the Tinius Olsen Testing Machine Co. and this company has prepared a booklet describing the instrument. It extends the reliable Brinell method for use with thin materials, case hardened or nitrided surfaces, small parts, or any condition where a small indentation is necessary or desirable.

815 **Electric Furnaces.**—Bulletin No. 260 sent out by the H. O. Swoboda Company describes their continuous furnaces for heat treating ferrous as well as non-ferrous strip metal and wire. Circular No. 228A by the same company gives a general description of their straight line continuous electric furnace equipments for hardening and tempering steel.

816 **Welding.**—The American Steel & Wire Company has compiled a booklet called "The Welder's Handbook." In it they discuss electric arc welding, as to selection of electrodes, arc length, welding current, etc. A few pages are devoted to gas welding and the remainder of the booklet is given over to illustrations of the various types of welding wire and electrodes.

817 **Wire Cloth.**—The Newark Wire Cloth Co., 351 Verona Ave., Newark, N. J., has published a leaflet illustrating the different meshes and weaves of their product. This company originated metallic filter cloths which cannot be excelled for some filtering purposes and are indispensable for others.

818 **Silver.**—A compact little book has been gotten up by the Handy & Harman Company. It is entitled "Review of the Silver Market for 1930" and gives not only an economic history of this metal for last year but gives the figures for its world production and consumption for 1929 and 1930.

819 **Welding.**—An interesting article on oxwelding brass and copper piping will be found in the June issue of "Oxy-Acetylene Tips." In this same issue there are also several articles on repair work done by welding, and a page listing new developments in this field.

820 **Testing Machines.**—A mimeographed pamphlet from the Riehle Bros. Testing Machine Co., 1424 N. 9th St., Philadelphia, Pa., gives the specifications of their Precision Hydraulic Universal Testing machine. The machine is built in three distinct units; the loading unit, the indicating unit and the power unit. Each of these is discussed separately and fully.

821 **Facts for Foundrymen.**—The second edition of this handy little book gotten out by the Niagara Falls Smelting & Refining Corporation, 2204 Elmwood Ave., Buffalo, N. Y., has just been received. It is bound in stiff boards, is pocket-size and gives a useful description of various metals and alloys that may assist in the production of more perfect castings.

822 **Nickel Steel.**—The International Nickel Company has issued numbers 1 to 8 of its Recommended Specifications for nickel alloy steel in railroad applications. These cover Forging Billets, Normalized and Tempered Low-Carbon Forgings, Boiler and Firebox Plates, Castings, Nickel Engine Bolt Steel, Low-Carbon Main Frames for Locomotives, Nickel Staybolt Steel and Nickel Cast Iron for Cylinders. These are put out in leaflet form and are punched for filing.

823 **Welding Rod and Equipment.**—Joseph T. Ryerson, Inc., have recently issued a bulletin in which the newer types of welding rod and equipment are illustrated. The first pages contain information on gas and electric welding rods. The second section is devoted to the subject of acetylene and welding equipment. This includes many improvements which have broadened the field of welding. This is Bulletin W.

824 **Steels.**—The Wehr Steel Company, Milwaukee, Wis., has printed a leaflet giving the physical analyses of established Wehr steels. This shows the tensile strength, yield point, elongation, reduction of area, Brinell and scleroscope qualities of their steels in the annealed, and heat treated and drawn states.

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Fifty-seven section editors and abstractors cover over 400 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstracts appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important. An improvement we hope to make in the METALLURGICAL ABSTRACTS in the near future is the cross-indexing of articles, which belong under several sections. Some of the sections are descriptive and some are self-explanatory and we have so labeled them.

CLASSIFICATIONS

0 (General). Under this heading we classify all abstracts which are of interest to the metallurgical industry in general. Compare this with Section 20—miscellaneous.

1, 2, 3 (Properties of Metals, Non-Ferrous and Ferrous Alloys). An article goes under one of these heads when the properties are emphasized and not the method of determining them.

4 (Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys). This takes articles on weather resistance, resistance to acids, etc., and protection against them.

5a (Structure of Metals & Alloys—Metallography & Macrography). An article would go in this group if it discussed the microscopic or macroscopic study of metals and alloys, or the determination of constitutional diagrams, critical points, etc.

5b (Structure of Metals & Alloys—Structure and X-Ray Analysis). This group includes articles dealing with the structure of metals and alloys as determined by X-ray analysis and X-ray examination.

6 (Physical, Mechanical & Magnetic Testing). If an article emphasizes the method of determining the properties of metals rather than the properties them-

selves it belongs in this section. The abstracts on fatigue appearing under this section are prepared with the coöperation of the Fatigue Research Committee of the American Society for Testing Materials.

7a (Electro-Chemistry—Electroplating). This will include articles on the electrolytic plating of metals.

7b (Electro-Chemistry—Electrometallurgy). This relates to the electrolytic recovery and refining of metals.

8 (Metallic Coatings Other than Electroplating). Articles on galvanizing, metal spraying or dip coating would come in this group.

9 (Industrial Uses and Applications). If the application of the metal is stressed rather than the properties the article belongs in this section.

10 (Heat Treatment). If heat treatment in general is discussed the article would be classed under section 10; if, however, any distinct operation is stressed it would go under the corresponding subhead.

11 (Joining of Metals and Alloys). The explanation for this group is similar to that for section 10.

12 (Working of Metals & Alloys). We feel that the divisions in this group are self-explanatory to men in the metals industries. We might say, though, that an article is classified under 12j (Cold Working) only when it will not fit under one of the other heads—for instance, an article on cold rolling would be put under 12c, rolling.

13 (Defects). This section includes articles dealing with inclusions, segregations, cracks, pinholes, blowholes and failures.

14 (Chemical Analysis). If the method of analysis is emphasized the article goes here.

15 (Historical & Biographical). Self-explanatory.

16 (Economic). Articles in this group are devoted to economic trends, savings, cost estimates, etc.

17 (Plants & Laboratories) This section includes descriptive articles.

18 (Machinery & Supplies). This includes descriptive articles.

19 (Bibliographies). Self-explanatory.

20 (Miscellaneous). This takes in all scattered articles which do not belong anywhere else.

21 (Laboratory Apparatus). Purely descriptive articles belong here. If results or processes are given they would go under 6 or 14.

22 (Foundry Practice & Appliances). This is self-explanatory.

23 (Furnaces & Fuels). This takes in descriptive articles. Otherwise they go under 10, heat treating, 10b, annealing, etc.

24 (Refractories & Furnace Materials). This section is hand-in-hand with 23. Furnace men should read both of them.

25 (Gases in Metals). This is self-explanatory.

26 (Inspection). This includes articles dealing with inspection, pure and simple—not X-ray or microscopic analysis.

27 (Effects of Elements on Metals and Alloys). Articles dealing with the effect of the addition of different chemical elements to metals and alloys are included in this group.

28 (Instruments & Controllers). Descriptive.

29 (Effect of Temperature on Metals and Alloys). This section is prepared in conjunction with the Joint High Temperature Committee of the A. S. T. M. and the A. S. M. E.

30 (Leaching). Self-explanatory.

31 (Reduction Metallurgy). This would include articles on blast furnace practice.

32 (Non-metallic Coatings for Metals and Alloys). Articles discussing painting, enameling, lacquering, etc., belong here.

◆ ◆ ◆ ◆ ◆

It has been our purpose in this outline to make our scheme of classification apparent to our readers and so, perhaps, make the abstract section more useful. If you have any questions pertaining in any way to the abstracts, write to us. We shall be glad to answer them in detail.

The classification number at the end of each abstract will be of assistance in mounting them on file cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

GENERAL (0)

Progress in the Iron and Steel Industry in 1930. Report of the Executive Committee, Iron & Steel Division, American Society Mechanical Engineers. *Mechanical Engineering*, Vol. 53, Jan. 1931, pages 48–50.

It is found that considerable progress has been effected in spite of adverse influences. Outstanding in its contrast to the general depression of the industry as a whole, is the extraordinary activity in the large-pipe or tube branch of the industry. One bright feature of the situation is the opening of research departments in a number of steel plants, although the amount of research actually carried on has been curtailed by the usual tendency of the steel industry in dull times to reduce expenditures for everything not considered directly productive. The report deals successively with blast furnaces, open-hearth furnaces, rolling mills, furnaces, alloy steels, structural steels, forging, welding, wrought iron, cast iron, surface treatment, billet chipping, machining, testing, and with miscellaneous developments. The Executive Committee notes especially the progress of Instrumentation. The serious application of automatic control to open-hearth furnaces has just begun. The use of metering devices and of automatic control has made the prevention of leakage into and out of the checkers an absolute necessity. In the rolling mill, the demand for greater accuracy and closer tolerances has led to the use of pyrometers which measure the temperatures at all points in the length of the bar while it is being rolled. In furnaces, atmosphere control developments are noted, and complete automatic control has already been achieved. MFB(0)

Emphasizes Physical Properties in Specifying Steels. JOHN JOHNSTON (United States Steel Corp.). *Yearbook, American Iron & Steel Institute*, 1930, pages 63–93, includes discussion; *Iron Trade Review*, Vol. 86, May 15, 1930, pages 51–52; *Metal Stampings*, Vol. 3, June 1930, pages 517–518; *Rolling Mill Journal*, Vol. 4, May 1930, pages 215–217; *Foundry Trade Journal*, Vol. 43, July 31, 1930, page 76.

Abstract of a paper read before the American Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. VSP + MS(0)

Waldorf-Astoria Steel Is Found Well Preserved. F. H. FRANKLAND (American Institute of Steel Construction, Inc.). *Steel*, Vol. 87, Sept. 4, 1930, pages 50, 52.

Tabulates results of chemical analysis and physical tests, made by the National Tube Co., of 15 specimens of structural iron and steel obtained during the demolition of the old Waldorf-Astoria Hotel, New York. Eight samples were of Bessemer steel, 5 of open-hearth steel, and 2 of wrought-iron. Only evidence of corrosion found was in 4 small Z-bar columns in the court where roof leaks had permitted rain-water to enter the interior of the scagliola column in casement. This corrosion amounted to less than 1% of the net section. Tests indicate that there has been no serious deterioration of the metals during their almost 40 years of service in the building. MS(0)

Metallurgical Research Aids Industry. ROBERT E. BELT (Malleable Iron Research Institute). *Foundry*, Vol. 58, Aug. 15, 1930, pages 73–74.

From a paper presented at a meeting of the American Trade Association Executives. Most of the coöperative research work in iron and steel has been along metallurgical lines for improvement of quality of product. Discusses coöperative work done by a number of associations allied to the iron and steel industry. VSP(0)

Aeronautical Industry Favors Army-Navy Steel Standards. *Steel*, Vol. 87, July 31, 1930, pages 49–50.

Report of the sixth annual Army-Navy Standards Conference held at Wright Field, Dayton, Ohio, in May 1930. New specifications adopted were those for 18–8 Cr-Ni corrosion-resistant sheet or strip; Cr-V medium steel bars and billets, SAE 6135 analysis; Cr-V high-C steel bars, SAE 6150 analysis; and C steel spring wire. Composition and physical properties specified are tabulated. Specifications for mild-C seamless steel tubing were revised; provision was made for corrosion-resistant tie rods made of 18–8 Cr-Ni steel. SAE 3140 or SAE 6150 were adopted as optional steels for bolts, plain and castellated nuts and fillister head screws. Steel for propeller clamp ring was changed to SAE 6135. MS(0)

Coöperative Research in the Iron & Steel Industry. F. N. SPELLER (National Tube Company). *Preprint* for May 1931 meeting *American Iron & Steel Institute*, 23 pages.

Technical research leading to better understanding of materials and processes may be divided into competitive and non-competitive. The latter problems generally refer to the principles involved, benefit the whole industry, and can be most economically solved by coöperative effort. The organizations for coöperative research in Germany and England are discussed in some detail. Considerable governmental assistance is given in those countries. Some of the societies and groups engaged in coöperative research and some important research topics they are undertaking, are mentioned. Special attention is given to the work on physical chemistry of steel making, which for five years has been coöperatively supported by the U. S. Bureau of Mines, Carnegie Institute of Technology and the iron and steel industry, through an Advisory Board. The Bureau of Mines is withdrawing from the coöperative arrangement, and in order to facilitate the continuation of this project and the handling of other analogous projects in the future, Speller suggests the establishment of a Central Research Board which would plan for carrying out coöperative researches that might be suggested to it, if it approved of them as worth while. It would budget the work, and arrange for its financing, and select a suitable institution to carry on the project. As a first step, he suggests that the steel industry take over on a more permanent basis the work on physical chemistry of steel making. HWG(0)

Aluminum, Light Metals and Light Alloys. (L'Alluminio—i metalli leggeri e le loro leghe.) E. KOELLIKER & U. MAGNANI. Ulrico Hoepli, Milan, 1930. Half-cloth, 4 × 6¼ inches, 468 pages. Price 34 Lire.

This pocket-size book takes up the subject of aluminum from the point of view of the Italian economic situation. It deals quite briefly with the alloys of aluminum, their properties and uses, but more extensively with the preparation of the metal itself. In various places, the authors indicate a decided leaning toward the Haglund process.

Since the technical data which this book gives are far more completely covered in Edwards, Frary and Jeffries "The Aluminum Industry," American readers will find the present volume interesting chiefly for its exposition of the Italian point of view.—H. W. Gillett (0)-B-

On What Test Value Should Working Stress Be Based? H. F. MOORE. *Machine Design*, Vol. 3, Feb. 1931, pages 35–38.

In the design of a machine part, the working stress should not be considered from the viewpoint of one kind of strength, but from the viewpoint of each possible kind of failure. The author discusses, as criterion for design, ultimate tensile strength, elastic limit and yield point, fatigue limit, significance of ductility, creep limit, corrosion fatigue limit and impact. He points out that accelerated tests are not reliable and that the factor of safety of the design depends on the consideration of all stresses mentioned which may enter into a particular case. Ha(0)

Fundamental and Test Relations between Elasticity, Plasticity, Hardness and Toughness. (Begriffliche und prüfmethodische Beziehungen zwischen. Elastizität, Plastizität, Härte und Zähigkeit.) M. ROS & A. EICHINGER (Materialprüfungsanstalt, Switzerland). *First Communications of the New International Association for Testing Materials*. 1930, Group D, pages 72–80, 7 references.

Definitions of the properties mentioned. HWG(0)

PROPERTIES OF METALS (1)

Report on the Measurements of Total Radiation of Aluminum Surfaces. (Bericht über Messungen der Gesamtstrahlung von Aluminiumflächen.) E. SCHMIDT. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, June 1930, pages 91–96.

Tests made on aluminum with different kinds of surfaces were made to determine the radiation constants. With all metallic surfaces, the radiation constant increases with temperature; with aluminum oxide, however, it decreases, at least for thin films. The test results of the different materials are reproduced in diagrams. Ha(1)

The Properties of Transmission Wires of Electrolytic Copper, Bronze, Aluminum and Aldrey in Tensile Tests and Vibration Stress. (Untersuchungen über die Festigkeitseigenschaften von Freileitungsdrähten aus Elektrolytkupfer, Bronze, Aluminium und Aldrey bei Zerreissversuchen und bei Schwingungsbeanspruchung.) W. SCHWINNING & E. DORGERLOH. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, July-Aug. 1930, pages 99–130.

These tests were made to determine the elastic and plastic behavior of the above named materials at static load and vibration stresses. Comparisons of the microstructure and electric conductivity were also determined. The results are given in detail in a great number of diagrams and tables and micrographs which cannot be given briefly but must be seen in the original. Ha(1)

Molybdenum in 1930. *Climax Molybdenum Co.*, 104 pages.

Since this beautifully printed booklet consists entirely of reprints or extended abstracts of articles in technical literature appearing in 1930, and contains no direct advertising, it deserves mention here rather than merely under "Manufacturers' Literature." Some 50 articles are thus abstracted. The article by S. B. Ritchie, Watertown Arsenal (Army Ordnance July-August, 1930; see *Metals & Alloys*, Vol. 1, Nov. 1930, page 856) is reprinted in full. Other articles and abstracts deal with Mo plus W in high speed steels, with nitriding steels, special alloy steels, forgings, steel castings, cast iron, heat-resistant steels, with automobile and aircraft uses, and with methods of chemical analysis for Mo. HWG(1)

The Properties of Pure Nickel. *Metal Industry*, London, Vol. 38, Apr. 17, 1931, pages 407–408; original paper by Louis Jordon and Wm. H. Swanger, *Bureau of Standards Journal of Research*, Vol. 5, Dec. 1930, pages 1291–1307.

A number of physical properties of Ni analyzing 99.94% are given. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 27. PRK(1)

The Physical-Technological Properties of the Aluminium Oxide Insulation Layer. (Die physikalisch-technologischen Eigenschaften der Aluminiumoxyd-Isolationsschicht.) H. SCHMITT & L. LUX. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, June 1930, pages 75–81.

Aluminum oxide has proved to be a fairly good electrical insulator so that the V. A. W. and the Aluminiumspulen G. m. b. H. have developed a special electrolytic method to produce a firmly adhering oxide film on the wire. Tests with such wires up to 5 mm. are described. The breakdown voltage is almost linear to the thickness of the film. The ratio of the wire to the radius of bending is of great influence; the smaller this ratio, the lower the breakdown voltage. The resistance of the oxide film can be represented by $R = R_0 e^{\frac{1455}{T}}$, where R is the resistance in ohms at the absolute temperature T, and R_0 is the final value at $T = \infty$. In general, it can be said that with further progress, this oxide-covered material will find a wide field of application. Ha(1)

The Metallurgy of Some of the Rarer Metals. C. J. SMITHELLS. *Metal Industry*, London, Vol. 38, Mar. 27, 1931, pages 336–338.

Text of paper read before Coördinating Committee, Chamber of Commerce, Birmingham, March 17, 1931. Ductile Zr is produced by deposition on W filament at 1300° C. from ZrI_4 which is formed at 400° C. from Zr and I_2. Zr is obtained from Na reduction of potassium zirconium fluoride. Ta is obtained from Na reduction of potassium tantalofluoride. The metal is pressed into bars and sintered and then must be fused in vacuum. Mo is obtained by hydrogen reduction of the lower oxide at 900–1200° C. Mo swaged above 1000–1100° C. is brittle but when worked at lower temperatures becomes ductile. PRK(1)

Hafnium. PAUL M. TYLER. *Information Circular* 6457, *United States Bureau of Mines*, April 1931, 11 pages.

The following subjects are discussed: description and properties, occurrence (list of minerals), identification and analysis, geographic distribution, history, separation of zirconium and hafnium, preparation of hafnium and zirconium, preparation of pure hafnium salts, and production. Contains 20 footnote references. AHE(1)

The Relations of the Magnetic and Thermal Constants of Ferromagnetic Substances. J. R. ASHWORTH. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Oct. 1930, pages 681–694.

The ferromagnetic substances considered are iron, cobalt, nickel, Heusler's alloy and magnetite. RHP(1)

Directional Properties in Cold-Rolled and Annealed Copper. ARTHUR PHILLIPS & E. S. BUNN (Yale University). *Technical Publication* No. 413, *American Institute Mining & Metallurgical Engineers*, 1931, 18 pages.

To determine the effect of inclusions on the directional properties of Cu, 2 kinds of Cu were studied. One, an electrolytic Cu deoxidized with P, contained no inclusions, while the other, a tough-pitch Lake Cu, of course, contained oxide inclusions. Sheets of the 2 materials were reduced from 10.5 to 89.9% by cold rolling, and the tensile properties parallel, perpendicular and at 45° to the direction of rolling determined. Very little difference was found between the properties in these directions with any reduction. The sheets were annealed at various temperatures and tested in the 3 directions. With large reductions and high annealing temperatures pronounced directional properties occurred. The included oxide apparently had little effect on the directional properties. In order to avoid serious directional properties in Cu it is recommended that the reductions be limited to 50 or 60% and the final anneal to 500° or 600° C. 7 references. JLG(1)

The Atomic Weight of Vanadium. ARTHUR F. SCOTT & CLYDE R. JOHNSON. *Journal American Chemical Society*, Vol. 52, July 1930, pages 2638–2648.

The analysis of vanadyl trichloride yields as the atomic weight of vanadium 50.947. MEH(1)

A Simple Method for the Measurement of the Specific Heat of a Solid Body at Ordinary Temperatures. Application to Beryllium. (Méthode simple de mesure de la chaleur spécifique d'un corps solide à la température ordinaire. Application au glucinum.) P. VERNOTTE & A. JEUFROY. *Comptes Rendus de L'Académie des Sciences*, Vol. 192, Mar. 9, 1931, pages 612–614.

After discussing the various causes of error which can enter into determinations of the specific heat of solid bodies by the method of mixtures, the authors describe a method which largely eliminates these errors. This method has been applied to the determination of the specific heat of beryllium, which was found to have the value 0.397 cal.-g./deg. at 13° C. OWE(1)

Physical Properties of Zinc of Interest to Wire Galvanizers. W. G. IMHOFF. *Wire & Wire Products*, Vol. 5, Sept. 1931, pages 348–349, 361–364.

Discussion of the physical properties of zinc. GN)1)

NEW PRODUCTS

Welding Torch and Cutting Apparatus

The Linde Air Products Company, New York, has recently made two new additions to its line of Purox medium pressure apparatus for oxy-acetylene welding and cutting.

The new Purox No. 11 welding torch, which supersedes the Purox No. 10 torch, has a very wide welding range extending from the lightest sheet metal up to work as heavy as $^1/_2$-inch plate. In spite of this wide range the torch is very light in weight and has perfect balance. The tips are of one piece, hard-drawn copper construction and are so designed that the head angle can be easily adjusted as desired by the user. Tips Nos. 2, 4, 6, 8 and 10 are furnished as standard equipment.

The Purox No. 21 cutting attachment designed for use with the Purox No. 11 welding torch will cut metal up to 2 in. in thickness. It is furnished with one and two piece cutting tips. By means of this cutting attachment the welding torch can be easily and quickly converted into a cutting torch. This is claimed to be the lightest cutting attachment on the market, weighing only 1 lb. 8 oz.

Fig. 1.—Purox No. 11 welding torch as supplied with five tips and wrench.
Fig. 2.—Purox No. 21 cutting attachment with two cutting tips and adaptor.
Fig. 3.—Prest-O-Weld Type C-105 cutting blowpipe.
Fig. 4.—Prest-O-Weld Type CW-105 cutting attachment.

An adaptor is also available which makes it possible to use the Purox No. 21 cutting attachment with the Purox No. 20 welding torch.

The new cutting apparatus includes the Prest-O-Weld Type C-105 cutting blowpipe and the Prest-O-Weld Type CW-105 cutting attachment.

These two types of cutting apparatus, together with the Types W-105 and W-106 welding blowpipes, can all be used interchangeably with the same detachable valve body. By means of the detachable valve body, the operator can change easily and quickly from a full size welding blowpipe to a smaller welding blowpipe, to a full size cutting blowpipe, or to a cutting attachment without detaching the hose or hose connections and without the use of a wrench.

The locking device for connecting the detachable valve body to any one of these blowpipe handles consists of a locking bolt and wedge-shaped locking screw. The locking screw is operated by turning a ring and draws the detachable valve body and blowpipe handle together making a gas-tight joint. The ring can also be used for hanging up the blowpipe when not in use.

Pressure forgings are used in the construction of the blowpipe head, cutting valve body and lever. The cutting oxygen tube is made of Ambrac, a special hard brass, to afford the necessary stiffness. The cutting nozzles have conical seats so designed that they will not become nicked or damaged if the nozzles should be accidentally dropped.

The blowpipe is light and well balanced, but at the same time it is of sturdy construction to withstand the hard usage to which cutting blowpipes may be subjected. It is furnished as standard with four cutting nozzles and a 75° angle head. If required, a 90° angle head can be furnished. Steel and wrought iron up to 12 inches in thickness may be easily cut with this blowpipe and metal of greater thickness can be cut by experienced operators.

The Prest-O-Weld Type CW-105 cutting attachment is of the single joint design and attaches directly to the valve body. It will readily cut metal up to 2 in. in thickness. Because of its small size, only 11 in. overall, it can be conveniently carried in the pocket of the operator when not in use. All the advantages of design and construction embodied in the full size Type C-105 cutting blowpipe are incorporated in this cutting attachment.

◆ ◆ ◆

Gas-Heated Soldering Iron

A gas-heated soldering iron was recently introduced by the Reliance Specialties Manufacturing Company, New York.

Low gas consumption is claimed, with the 3-lb. head, the fuel required is only 4 or 5 cu. ft. of gas per hour, and with the 5-lb. head, 5 or 6 cu. ft. of gas per hour.

This iron is heated by either natural or artificial gas and low pressure air mixed by means of a needle valve, and passing through a flexible hose to the handle of the torch, making it very easy to operate.

Constant temperatures are increased or decreased at the option of the operator by regulation of the needle valve. The copper heads may be brought to a red heat within 3 to 5 minutes after lighting. A great deal of the filing and cleaning, dipping and retinning of the coppers is eliminated, inasmuch as the copper heads are not exposed to the open flame.

Coppers are available in sizes ranging from $^1/_2$ to 5 lbs. They also are made to specifications. The coppers are quickly interchangeable, being screwed onto the stainless steel tip. The "Torchiron" may be used as a torch as well as an iron, merely by removing the copper head.

◆ ◆ ◆

New Low Melting Point Brazing Alloy

Handy & Harman, New York, producers of sterling silver sheet metal and wire, silver solders and silver alloys in general, have applied for a patent on a new brazing alloy, "SIL-FOS." It contains a small percentage of silver and is described as flowing freely at 1300° F.

"SIL-FOS" promises to be worthy of consideration where higher melting point base-metal brazing or welding alloys cannot be used without danger of weakening, distorting or destroying the parts adjacent to the joint.

"SIL-FOS" is described as also possessing free-flowing properties, with deep and quick penetration. This characteristic is doubtless due to the silver in the alloy. In addition, it is pointed out that at 1400° F., the flow point of borax flux with which it is generally applied, there is 100° of superheat which increases the fluidity still further and aids penetration and alloying action.

Another feature claimed for "SIL-FOS" is that it requires less

(Continued on Page 162)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Directions for the Working of Silumin in the Foundry. (Richtlinien für die Verarbeitung des Silumins in der Giesserei.) DR. DORNAUF. *Aluminium, Hauszeitschrift der V. A. W. und Erftwerk*, Vol. 3, Jan.-Mar. 1931, pages 86–114.

An extremely instructive and exhaustive work illustrating the right and wrong way for preparing molds, castings, refining, temperature measurements. The mechanical-technological properties of silumin are described and illustrated in curves and diagrams and the third part is devoted to the physical-chemical properties of cast aluminum alloys with special reference to Al-Si alloys. All this information is in a handy form for ready use in practice. Ha(2)

Structure and Conductivity of Hard-Drawn Copper Wire. R. W. DRIER & C. T. EDDY. *Wire & Wire Products*, Vol. 5, Nov. 1930, pages 424–425, 436–437.

The article gives the results of investigations on the effect of the direction of drawing crystal orientation on the specific resistivity of hard-drawn copper wire. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 425, "Correlation of the Ultimate Structure of Hard-Drawn Copper Wire with Electrical Conductivity." GN(2)

Simple Aluminum Cast Alloys. (Einfache Aluminium-Gusslegierungen.) WILLI CLAUS. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 3, Jan.-Mar. 1931, pages 54–66.

A short historical sketch is given of the development of pure aluminum and the alloyed aluminum materials. Two main alloys exist to-day: the American aluminum cast alloys which are binary copper-aluminum light metals (*without* zinc), usually 8% Cu and 92% Al, and the German aluminum cast alloys of a ternary type, Cu-Zn-Al, usually 2% Cu, 10% Zn and 88% Al. The latter form the basis for further alloys with Si, Mn, Ni, Mg and others. The density of the 2 main alloys is 3.1 for the German and 2.85 for the American. The diagrams of state, mechanical properties, instructions for melting, influence of pouring temperature on properties, disturbances by solid and gaseous impurities are described. The fields of application and possible economies are discussed and the path for further development shown. So far, special alloys for pistons, corrosion-proof and sea waterproof alloys have been developed. Ha(2)

Copper and Copper Alloys. W. H. BASSETT. *National Electric Light Association Bulletin*, Vol. 17, 1930, pages 275–278; *Mining & Metallurgy*, Vol. 11, Dec. 1930, pages 562–564.

A general discussion with special attention given to the newer alloys such as Cu-Be alloys and Everdur (Cu 96%, Si 3% and Mn 1%), and a Cu alloy containing 0.5–3.0% Cr. Comparison of the properties of Cu and Cu alloys and a comparison of Cu-Be alloys with Cu-Sn, and Cu-Cd alloys and corrosion tests on cast Everdur and cast 85–5–5–5 are tabulated. WHB+VSP(2)

The Composition of Manganese Amalgam and Manganese Silver Alloys in Relation to the Electrode Potential of Manganese. HARVEY D. ROYCE & LOUIS KAHLENBERG. *American Electrochemical Society, Preprint* 59–11, April 1931 meeting, 13 pages.

Four manganese-silver alloys were prepared from highly purified materials. Electrode potentials and replacing power of these alloys have been measured. The replacing power and potential of alloy D (31 atomic % Mn) were correlated with alloy structure by means of photomicrographs and thermal diagrams. None of the manganese-silver alloys yields electrode potential approaching to that of manganese amalgam: Manganese amalgam consists of solid Mn_2Hg_5 in equilibrium with a very dilute solution of manganese in mercury (0.0032% Mn). The behavior of manganese amalgam in contact with manganese salt solutions has been interpreted on the basis of these figures. A new compound of manganese and mercury, isolated from the dilute amalgam by the application of pressures exceeding 150,000 lbs./in.^{2} (10,500 kg./cm.^{2}) and having the formula MnHg, is described. MnHg constitutes the stable solid phase in the system Mn-Hg at temperatures between 86° and 100° C. Pressure-concentration curves are presented to justify the assumption that the solid phase obtained by pressure is MnHg contaminated with a small percentage of the liquid amalgam. (2)

Zinc and Its Alloys. (Le Zinc et ses alliages.) R. CAZAUD. *Aciers Speciaux, Métaux et Alliages* Vol. 6, Feb. 1931, pages 69–74.

Alloys commercially used are of three types: (1) 6% Sn, 3% Cu, 0.5% Al and 90.5% Zn. (2) 3% Cu, 4–5% Al, 93–92% Zn. (3) 3% Cu, 4% Al, 0.1 %Mg, 92.9% Zn. Binary Zn alloys discussed are: Zn-Al, Zn-Mg, Zn-Cd and Zn-Cu, giving equilibrium diagrams for Mg-Zn and Al-Zn. GTM(2)

A Research of Light Cast Alloys. B. OTANI. *Kinzoku no Kenkyu*, Japan, Jan. 1931, pages 43–52.

Silumin is not suitable for castings of complex form, as blow holes readily form. The author carried out number of tests of shrinkage, fluidity, mechanical and physical properties for great many alloys of modified Lautal and Silumin. The results showed that the following alloys were recommended for casting; Al-Cu-Si alloys containing 3.5% Cu, 4.5% Si and 0.1% Mg, or 6.5% Cu and 3.5% Si, and modified silumin containing 0.8% Cu, 8% Si, 8% Zn. Aluminium Alloy Manufacture. *Automobile Engineer*, Vol. 20, Oct. 1930, pages 357–364.

Group of alloys patented by Rolls-Royce, Ltd., and known as R. R. alloys have a composition of: copper 0.5–5%, nickel 0.2–1.5%, magnesium 0.1–5%, iron 0.6–1.5%, titanium up to 0.5%, silicon 0.2–5%, aluminum the remainder. From this composition, 4 grades are manufactured. Details of manufacture for each grade, testing, and X-ray examination of the parts are discussed. RHP(2)

Japanese Art Bronzes. (Ueber japanische Kunstbronzen.) EDMUND RICHARD THEWS. *Deutsche Goldschmeide-Zeitung*, Vol. 34, Apr. 25, 1931, pages 170–171.

Many of the Chinese or Japanese art bronzes contain appreciable quantities of Ag and Au. The bronzes were frequently colored by various methods, including etching. Some of the oldest alloys were probably made by direct reduction of the ores. The compositions of several solutions used for etching the bronzes are given. Remarkable effects were sometimes produced by casting from only partially molten metals. Contains 1 reference. JLG(2)

Brass, Bronze, and Other Copper Alloys for Spring Making. *Mainspring* (Wallace Barnes Co.), Vol. 4, Jan. 1931, pages 2–4.

Summarized properties of spring brass, phosphor bronze, monel metal, nickel silver and hardened copper. MFB(2)

The Austenite-pearlite Transformation and the Transition Constituents. ALBERT SAUVEUR (Harvard University). *Technical Publication* No. 412 *American Institute Mining & Metallurgical Engineers*, 1931, 6 pages.

It is just as impossible for austenite to transform to pearlite without passing through the intermediate constituents, martensite, troostite and sorbite, as it is for water to freeze without passing through the stage water and ice. The exact mechanism of the austenite-pearlite transformation is discussed. 1 reference. JLG(2)

Rise of the Break in Tensile-Strength Curve of Metals due to Strain and Aging. (Sur le relèvement du palier de la courbe de traction des metaux par traction et vieillisement.) J. GALIBOURG. *Comptes Rendus*, Vol. 188, Apr. 8, 1929, pages 992–995.

Curves are given representing variation of rise for extra-soft steel as function of time. See *Metals & Alloys*, Vol. 1, Nov. 1929, page 241. (3)

Gray Iron Possesses Valuable Engineering Properties. Part VIII. *Foundry*, Vol. 58, Sept. 1, 1930, pages 94–97, 101.

Discusses results of various investigators on the determination of properties of gray iron and their interpretation. The shear tests for cast iron have been proposed. The relation of shear to tensile test indicates a nearly constant relationship. Shear tests should run consistently higher than tensile tests. In chill or in high phosphorous irons this relationship does not apply. Tabulates results. VSP(3)

Gray Iron Possesses Valuable Engineering Properties. *Foundry*, Vol. 58, Oct. 1, 1930, pages 83–85; Nov. 1, 1930, pages 86–88, 118; Dec. 1, pages 76–79, 103–104.

Gray iron must possess resistance to shock and vibration as well as sufficient static strength. High strength Fe possesses greater impact resistance than the weaker Fe. The Izod and Charpy impact testing machines are used. The main reason that impact value of gray Fe is low, is the presence of weak graphite flakes. This influence is modified by the nature of the metallic matrix which is composed of pearlite, ferrite and steadite. Impact value of cast Fe is proportional to the work under the stress-strain diagram. For high impact resistance lowering the C and P is advantageous. Fatigue tests show: (1) Endurance limit of gray Fe is about $^1/_2$ the ultimate tensile strength when test piece is protected from external vibrations. (2) Values for endurance limit are not reduced greatly up to 800° F.; above 1250° F., endurance limit is as high as tensile strength. (3) Tests on range stress indicate that endurance limit from stresses from zero to a maximum tension are about $^1/_2$ times the limit for completely reversed flexual stress. Brinell test is the most common hardness test applied to gray Fe. Fe composed of all ferrite and graphite is likely to have a Brinell number of 100. Such Fe is low in tensile strength. Pearlite, the eutectoid of ferrite and cementite, offers resistance to indentation and the Brinell of pearlitic Fe is around 200. Such Fe possesses good strength and wearing properties. Hardness may be increased by changing the form of the combined C. Relation of Brinell to other physical properties of gray Fe has been suggested by Portevin, using the formula $K_z = 0.2H - 13$, where H = Brinell number and K_z = tensile strength expressed in kg./mm.^{2} Schuez proposed $K_z = \frac{H - 40}{6}$. Brinell test is also useful as an indicator of uniformity of hardness and shows presence of spongy and unsound areas. Specific gravity of commercial high carbon Fe at room temperature varies from about 6.95 for open grained high carbon Fe to 7.35 for closed grained low carbon metals. The specific gravity of the ordinary structural components of gray Fe at 15° to 20° C. are: ferrite, 7.85–7.88; graphite, 2.26; cementite, 7.66; pearlite, 7.74; iron phosphide 6.74; steadite, (about) 7.14; iron sulphide, 5.02; manganese sulphide, 3.99. Highest strength values are found in Fe free from microscopic shrinkage. Metals' expansions and contractions are due to: change in volume with change in temperature, structure of metal constant; change in volume due to change in state and change in volume due to change in constitution. Gray Fe contraction may be liquid or solid. Discusses results of other investigators on the contraction of gray Fe. When liquid Fe changes to solid there is a marked contraction occurring over a short range of temperature. More shrinkage defects, drawholes and spongy spots are due to illogical design than to all other causes together. Risers are used to feed castings. Proper gating is essential to production of sound castings. VSP(3)

"Tungum Metal." *Metal Industry*, London, Vol. 38, Apr. 3, 1931, page 365.

"Tungum" is a new anti-corrosive alloy which is strong, very ductile and obtainable in castings, tubes, sheet, wire. A table lists the corrosion resistance to numerous acids. PRK(3)

Arbed-super Cobalt High Speed Steel. (Acier extra-rapid Arbed-super Cobalt.) *Aciers Speciaux, Métaux et Alliages*, Vol. 6, Feb. 1931, page 80.

A new high speed steel of the chemical composition: C, 0.78–0.80%; Cr, 4%; W, 18%; V, 1.50%; Co, 18%; Mo, 0.50%, has been developed which performs better than any high speed steel. It is used for cutting cast iron, hard steels and 12–14% Mn steel. GTM(3)

Effect of Rolling Reduction, Finishing Temperature and Heat Treatment on the Physical Properties, Aging and Structure of Thick Sheets. (Einfluss des Walzgrades, der Walzendtemperatur und der Wärmebehandlung auf die mechanischen Eigenschaften, die Alterungsempfindlichkeit und das Gefüge von Grobblechen.) F. KÖRBER & K. WALLMANN. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, No. 13, Report 156, pages 171–191.

Four different steels with varying C, Si and Mn content were rolled to sheets, 25, 20 and 15 mm. thick, with temperatures of 900°, 800° and 700° C. at the finish and tested after normal air cooling, cooling in a pile, annealing below and above the upper critical point and subsequent furnace or air cooling. The same 4 steels were also tempered either by quenching in hot water or by quenching and drawing at 600° and 400° C., respectively. The tensile strength, yield point, 0.2 limit, limit of elasticity, elongation, reduction of area, notch toughness and sensitivity toward aging were tested. Low rolling finishing temperatures bring about a fine grain, increase the limit of elasticity and yield point without essentially affecting the tensile strength. Low finishing temperatures, however, greatly impair the notch toughness of low carbon steel. The notch toughness of higher carbon steels is either not affected or, in part, improved by a lower finishing temperature. Annealing does not affect elongation and reduction of area to a large extent. Retarded cooling after annealing brings about poor physical properties and coarse grain. Thin sheets show aging effects to a smaller degree than thick sheets. GN (3)

Progress in Steel Manufacture. L. K. EVERITT. *Edgar Allen News*, Vol. 9, Sept. 1930, pages 698–700.

Properties and uses and 2 tables summarizing the analysis, heat treatment and tensile tests of a Ni-Cr and a Ni-Cr-Mo steel. ACW(3)

Alloys of Iron, Nickel and Chromium. M. A. GROSSMAN (Central Alloy Steel Corporation). *First Communications of the New International Association for the Testing of Materials*. Group A, Zurich, 1930, pages 97–103.

General description of constitution, properties and uses of these alloys. HWG(3)

Requirements, Properties and Testing of Steel Wire for the Manufacture of Bolts. (Auforderungen, Eigenschaften und Prüfung von Stahlstauchdrähten für die Schraubenfertigung.) WILLY AUMANN. *Stahl und Eisen*, Vol. 50, Nov. 13, 1930, pages 1611–1616.

The paper deals with the relations between the processing of bolts and the steel quality, the failures occurring and the difficulties due to the bolt making process, itself. Reference is made to the technological properties of the wire used as well as the composition. Finally, rules are given to standardize the testing of the wire as well as investigations on the processing of bolts. GN(3)

than the usual amount of flux because of the deoxidizing effect of the phosphorus in the alloy. This would seem to be an important advantage and should tend to reduce the cost of cleaning and finishing after joints have been made. Under certain conditions, satisfactory copper to copper joints can be made without using any flux.

As to strength, the makers report, for example, that lap joints of copper sheets show tensile strength of approximately 30,000 lbs. per square inch. They also claim that "SIL-FOS" can be used in many cases for joining brass, bronze, nickel, nickel-silver, extruded brass and bronze, monel metal, and other metals and alloys fusing above 1300° F.

While containing silver, "SIL-FOS" is not classed as a silver solder.

Tensile Strength Tester

For determining the tensile properties of metal sheets and wires the new model Amthor Tensile Machine, developed by the Amthor Testing Instrument Co., Inc., is claimed to embody many new improvements in design, operation and control, and provides a complete and exact test evaluation in a comparison graphic record.

It is what is known as a vertical, pendulum type, motor driven machine. The pulling force is applied to the pulling clamp through the test specimen and to the upper clamp, which is directly connected to the pendulum or indicator arm. Pawls are provided to hold the indicator arm at the exact breaking point on the graduated scales when the specimen breaks.

Operation of this model has been even further simplified and is controlled throughout the test. Once the control lever is set, the tester operates by itself and requires no further care. When the specimen breaks, operation automatically ceases and the tensile strength is pointed out, locked on the graduated scales, of which there are two; one scale for the high capacity and the other for the low. By having two separate capacity ranges and with a separate graduated scale covering each, it is possible to use the tester for testing the heavier specimens, without affecting its accuracy or sensitivity for testing the much lighter specimens. In addition, much finer and closer readings can be obtained.

The recording unit operates automatically in conjunction with the indicator, and produces as complete and exact an evaluation of the metal's physical properties as it is possible to obtain with this type of test. The chart not only shows the exact tensile strength, elongation and the proportion of elongation to the increasing load, but also the entire action of the metal under test. It plots a curve showing the action of the specimen from the instant of first tension under load to the last minutest elongation when the molecules have separated after the yield point. To further simplify the reading the chart is quadrilaterally subdivided. Several tests can be made on the same chart, thereby allowing a minute comparison of all tests to be made together. If desired, the tester can be had with elongation scale instead of recording unit.

A $^1/_6$ H. P. constant speed motor is permanently mounted directly on the base of the tester and operates the pulling clamp through the variable speed control unit. By means of this unit, these pulling speeds can be varied according to the specific metal being tested. The whole tester stands only about 3 feet high, and is compactly designed. The important moving mechanism is encased in a special dust-proof metal housing into which no particles of the test specimens can enter.

Electric Welding Torch

An electric welding torch that operates from an ordinary 110 v. or 220 v. A. C. lighting circuit has been perfected and now is being manufactured by the Warner Engineering Company, Pomona, Cal. By means of transformer coilation and a magnetic

effect a smooth, steady flame is produced between carbon electrodes.

Models operating on 110 volts will weld virtually all metals including aluminum and can also be used for hard soldering with German silver and silver solder. The 220 v. models are for heavier work and a special 220 v. welder is made that in addition the flame feature can be used for carbon and metallic arc welding.

The flame produced between the carbon electrodes is extremely flexible in use and is non-oxidizing. Heat control is obtained by using different switch taps in the transformer box and by varying the distance between the electrodes. Flame volume may be regulated by different sized electrodes.

Ease of portability of the device and the convenience of power always available to any electric socket, make the welder adaptable to almost any kind of work.

New 30″ and 36″ Heavy Duty Engine Lathes

Some of the most interesting features claimed for Tritro heavy duty engine lathes are: direct reading 16 speed control; the totally enclosed anti-friction self-oiling gear box; anti-friction end gearing and the anti-friction centrally oiled apron. One of the biggest advances in engine lathe design is found in the method of guiding and holding the carriage to the bed. The carriage is guided on the bed by large vees front and back and a wide flat bearing is placed under the bridge where the tool pressure comes. The gibs are located in the center of the bed on square guides which not only keep the carriage from lifting under the heaviest cuts, but also strengthens the bridge considerably. The bed is a four wall construction, cast from 0.50 to 0.60 carbon, 1% nickel steel.

The headstock is full herringbone gear design and operates on anti-friction bearings. All bearings are adjustable for take-up from outside the headstock without removing the cover. A positive force feed lubrication system assures a constant flow of clean, fresh lubricant to all bearings and moving parts in the headstock.

The spindle and all drive shafts are made from alloy steel forgings. The spindle is of exceptionally large diameter. The positive jawed clutch together with the herringbone geared headstock makes possible sudden spindle speed changes without danger of damaging of the work, tool or machine.

The gear box is dust proof and chip proof. It is lubricated by a central oiling system.

The heavy double walled apron is equipped with anti-friction bearings. The non-revolving snap lever apron controls, it is claimed, can be thrown out or in with a flip of the finger yet they will not slip out of engagement under the heaviest loads. A lever on the aprons provides a reverse to all feeds without reversing the spindle.

These lathes are manufactured by the Sidney Machine Tool Company and distributed by Joseph T. Ryerson & Son, Inc., Chicago.

The Effect of Supports on the Catalytic Activity of Nickel. CHARLES R. GLASS & LOUIS KAHLENBERG. *American Electrochemical Society, Preprint* 59–13, April 1931 meeting, 18 pages.

Those support materials which inhibit the catalytic activity of Pt and Pd have been found to affect Ni similarly. The behavior of the supports with relation to the hydrogenation of cotton-seed oil by Ni can be classified as follows: Reducible heavy metal oxides completely inhibit the activity of Ni. The salts of those metals that decompose on heating in a stream of hydrogen, completely inhibit activity. The salts in every case have been found to yield more active supports than the corresponding oxides. The more inert the support becomes toward Ni, the greater is its tendency to enhance activity. The less inert the support becomes toward Ni, the greater is its tendency to retard activity. The oxides of Si, Al, Cr, Mn, Ti, Ce, U and Mg, and the phosphates and borates of Al, Cr, Mn, Ce, U, Mg, Ca, Sr, Ba and Li proved very beneficial as supports for nickel in hydrogenation. (4)

Method for Checking the Local Element Theory of Corrosion. (Verfahren zur Prüfung der Lokalelmenttheorie der Korrosion.) W. GUERTLER & B. BLUM. *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 118–119.

Corrosion in Tanks and Tankers. J. FOSTER KING & J. L. ADAM. *Advance Copy, North-East Coast Institution of Engineers and Shipbuilders*, Apr. 17, 1931, 8 pages.

The paper describes forms of corrosion and erosion to be expected in tanks used for the transportation in bulk of liquid cargoes under varying conditions of service. Attention is also drawn to factors which affect the rate or extent of corrosion, quality of material, protective coatings, upkeep, etc. Particulars are given of the different corrosive effects of water, heavy oils and spirit upon tank structures and details of actual cases are cited. Attention is drawn to the association of durability and cost of maintenance, with necessary freight charges and cost to consumers. The paper as a whole relates observed facts with probable causes and cures in the hope that discussion will promote collaboration between metallurgists, chemists, builders and owners in efforts to promote a better knowledge of the causes and effects of corrosion and an improvement in the economics of the transportation of fluids in bulk. (4)

A Note on the Tarnishing of Chromium-Plated Brass. W. M. PHILLIPS. *American Electrochemical Society, Preprint* 59–36, April 1931 meeting, 2 pages.

In the St. Louis district chromium-plated articles appear to have tarnished. Investigation shows that where no nickel or insufficient nickel is first plated over brass or copper articles, this type of failure can occur. (4)

The Open-Air Corrosion of Copper. II. The Mineralogical Relationships of Corrosion Products. W. H. J. VERNON & L. WHITBY. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 389–408.

Heat Treatment of Chromium Deposits to Increase Their Resistance to Corrosion. R. J. WIRSHING (General Motors Corp.). *Metal Industry*, N. Y., Vol. 28, Dec. 1930, page 557; *Metal Cleaning & Finishing*, Vol. 2, Nov. 2, 1930, pages 959–960.

From a paper presented before the American Electrochemical Society at Detroit, Sept. 25–27, 1930. Heat treatment seems to offer a means of increasing the resistance of Cr deposits to many forms of corrosion. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 902. MS+VSP(4)

Corrosion-Resisting Steel. *Power*, Vol. 70, Nov. 19, 1929, page 808.

A corrosion-resistant steel intended to resist the action of hot weak solutions of sulphuric acid is being produced under the name "Durimet" by the Duriron Co., Inc., Dayton, Ohio. Three varieties are available: Grade A containing 25% Ni, 5% Si, traces of Cr and 0.25% C; Grade B containing 35% Ni, 5% Si, 12% Cr and 0.25% C; Grade D containing 15% Ni, 3% Si, 2.5% Cr and 0.60% C. The A and B grades can be furnished in the form of hot or cold-rolled bars, sheets and plates ground and polished shafting, wire, rivets, bolts and nuts and castings. The D grade is furnished only in the form of castings. The B grade shows good resistance to hot glacial acetic acid and can be used for ventilating fans and ducts, towers and similar equipment handling entrained sulphuric acid and laboratory fumes. The D grade has approximately the same acid-resisting qualities as the A grade. VVK(4)

The Use of Aluminum for Oil Lease Tanks. Part 1—Field Tests. LUDWIG SCHMIDT, JOHN M. DEVINE & C. J. WILHELM. *Report of Investigations* 3066, *United States Bureau of Mines*, April, 1931, 17 pages.

Tests are described which indicate that under certain operating conditions aluminum has promising possibilities as a material for the construction of lease tankage because of its resistance to the corrosive action of hydrogen sulphide gas. The use of aluminum steam coils in flow tanks or stock tanks where the coils come in contact with salt water is not practical. It is possible that other forms or alloys of aluminum may be developed that will be successful in resisting high temperature salt water corrosion. Certain fittings of No. 43 alloy resisted such corrosion. The aluminum tank plate used did not prove highly resistant to the corrosive action of concentrated brines as was shown by deep etching in those areas of the side sheets which had been subjected to the action of salt water for an extended period. In places where aluminum is used in conjunction with steel, extreme care must be taken that no electrolyte is present. 7 references. AHE(4)

Sea Water Resistance of Various Anti-Corrosion Coatings on Iron and Light Alloys. E. K. O. SCHMIDT. *Automotive Abstracts*, Vol. 9, May 1931, page 157. Original in *Zeitschrift Flugtechnik und Motorluftschiffahrt*, March 14, 1931, pages 141–147; *Korrosion und Metallschutz*, Vol. 7, Apr. 1931, pages 111–112.

Practical observations on corrosion prevention in sea planes. For steel, cadmium plating is recommended, a Cd-Zn mixture is less effective than Cd Zn has only temporary value. The 18–8 type of steel is practically uncorroded. Cadmium plating on duralumin and Lautal generally gave good results, but it should not be used on electron. Rubber coatings seldom gave satisfaction. The Influence of Sodium Chloride Solutions of Various Concentrations upon the Course of Corrosion Attack in the Alternating Submersion Test. (Einfluss von Kochsalzlösungen verschiedener Konzentration auf den Verlauf des Korrosionsangriffs im Wechseltauchversuch.) E. K. O. SCHMIDT. *Korrosion und Metallschutz*, Vol. 6, Nov. 1930, pages 250–255.

Alternating submersion tests were performed on 0.5 mm. Lautal samples in salt solutions of 3, 5, 10 and 20% NaCl solutions and the corrosion attack investigated by visual and micro-examination and by determination of the loss in physical properties. Regarding the concentration of the corrosion medium, differences were only found in the beginning of the tests. At later stages the concentration does not matter. The loss in physical properties during the corrosion attack, however, is essentially smaller in the 1% NaCl solution. In conclusion, the author tries to interpret the phenomenon of corrosion attack. EF(4)

ILLIUM is not a "new" alloy. It has been in successful use more than 15 years, sometimes in acids—sulphuric, nitric, acetic, phosphoric, *mixed* nitric and sulphuric, etc.—sometimes in alkalies.

While not a cure-all for every ill, ILLIUM *is* a complete, permanent and moderate priced answer to many of the corrosion troubles commonly encountered.

Dense, close grained, with considerable tensile strength, ILLIUM withstands heat, torque, impact and wear. It is especially recommended for pump and valve parts, agitators, or pieces requiring accurate machining.

Outdoor Corrosion of Protective Zinc Coatings. C. L. Hippensteel, C. W. Borgmann & F. F. Farnsworth. *Proceedings American Society for Testing Materials*, Vol. 30, 1930, Pt. 2, pages 456–472.

Sherardized and hot-dipped zinc coated steel specimens exposed to the outdoor atmosphere in New York City lost weight at the same rate. The attack upon the zinc and upon the iron-zinc alloy layer went on at the same rate. Simulation of additional rainfall by water-spraying the outdoor specimens speeded up the attack without affecting relative performance of the coatings. This gives more reliable information than does any accelerated laboratory test. In discussion, it was brought out that most laboratory tests give erroneous indications in respect to the rate of corrosion of the iron-zinc alloy layer. HWG(4)

Contribution to the Evans Theory. (Beitrag zur Evansschen Belüftungstheorie.) E. Herzog & G. Chaudron. *Korrosion und Metallschutz*, Vol. 7, Jan. 1931, page 1; E. Maass & E. Liebreich, pages 2–3.

Continuation of the controversy on the value of the drop corrosion test and the interpretation given by Evans. See *Metals & Alloys*, Vol. 2, Mar. 1931, page 84. EF(4)

Use of Aluminum in Chemistry. (Die Verwendung des Aluminiums in der Chemie.) P. Drossbach. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 39–44.

The property of aluminum, in solutions at anodic polarization, to develop a very thin film which protects it against corrosion makes it particularly adaptable for apparatus in chemistry. This film has an extremely great resistance to electric currents which accounts for the great resistance of aluminum to corrosion. The theory of corrosion by local elements is briefly explained. 3 pages of test results with inorganic solutions are given, showing the loss of weight of aluminum. By reference to these tables, it can be ascertained at once whether aluminum can be used in contact with a certain solution. Ha(4)

On the Corrosion of Lead Pipes. (Ueber die Korrosion in Bleirohren.) W. Obst. *Korrosion und Metallschutz*, Vol. 7, Jan. 1931, pages 12–13.

Author reviews the corrosion of lead pipes starting from both inside and outside. The insulation in moist brick work and in earth is stressed and the various possibilities outlined. EF(4)

Weather-Resistant Steels—Especially Copper Steels. (Witterungsbeständige Stähle mit besonderer Berücksichtigung der Gekupferten Stähle.) W. Mattheis. *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns*, Vol. 1, Sept. 1930, pages 2–7, 13 references.

Résumé of published literature favorable to the use of copper steel. Emphasis is placed on the adherent nature of the rust formed upon it. No new data are given. HWG(4)

Stress and Corrosion. D. J. McAdam, Jr. (Naval Expt. Sta.). *3d. International Congress for Applied Mechanics*, Stockholm meeting, August 1930, Separate pamphlet, 25 pages, 13 figures.

General summary of McAdam's work on corrosion-fatigue, presented in 15 previous papers. Boiler corrosion under steady stress and under repeated stress, is considered in some detail. HWG(4)

Corrosion of Iron by Carbon Tetrachloride. (Contribution a la connaissance de la corrosion du fer pa le tetrachlorure de carbone.) J. Milbauer. *Collection Czechoslovak Chemical Communications*, Vol. 3, Jan.-Feb. 1931, pages 73–75.

Iron is corroded by CCl_4 in presence of ethyl alcohol and water. A test made, consisted in boiling iron for 1 hour in a mixture of CCl_4, ethyl alcohol, and water. The results obtained were:

CCl_4	C_2H_5OH	H_2O	Fe dissolved
80%	11%	9%	0.24 grams
50	41	9	0.93
30	60	10	0.9
80	18	2	1.04
45	5	50	0.13
90	9.1	0.9	0.63
70	27.3	2.7	1.81
70	20	10	0.74
70	10	20	0.16
100	0	0	0
0	100	0	0

Maximum corrosion is obtained with a mixture of 70% CCl_4, 27.3% ethyl alcohol and 2.7% water. The presence of alcohol favors the corrosion of Fe by CCl_4. GTM(4)

Boiler and Tender Corrosion and Pitting. *Boiler Maker*, Vol. 30, Nov. 1930, pages 313–321.

Condensed report of a committee (O. H. Kurlfinke and C. W. Buffington) of the Master Boiler Makers presented at the May 1930 convention. Corrosion, which is a chemical action set up between the acids in the water and the metal, varies quite materially, depending upon the composition of the metal in the sheets and the nature of the acids in the water, but can to a great extent be overcome if the water can be kept moving. Pitting, which is due to dissolved gases, occurs when the boiler is merely warm to a much greater extent than when it is hot and in service. Preventive measures for both corrosion and pitting lie through the medium of keeping the water moving. The size of the modern locomotive boiler has contributed to corrosion and pitting because of the increased amount of water evaporated compared to years past, and because of the difficulty in stimulating circulation of the water due to the increased length of the boiler. Various methods and devices for assisting circulation of the water such as the arch tube, the Nicholson thermic siphon, and the Martin circulator are discussed. Continuous and rapid circulation of water through the barrel of the boiler means an

New Method

Old Method

equalization of the temperature of the water surrounding the tubes, greatly increasing their life and utility and aiding in preventing pitting and corrosion of boiler shell and firebox sheets. Removal of dissolved oxygen from the boiler water by various devices has also cut down corrosion. Examples are given. The committee also suggested an improved design of girth seam to eliminate grooving of the shell plate at the inside calking edge. Care should be taken of the materials before they are applied to the boiler in order to prevent rust and atmospheric corrosion from starting and roughening the surface of the metal. Various commercial compounds such as "Oxaline" can be used for this purpose. Cleaning the boiler with 40 to 80 lbs. of soda ash before firing or spraying with 3 quarts of cement to 1 gallon of water when the boiler is in the shop for repairs is effective. In the corrosion of tenders paints have been unsatisfactory. Coating the inside with cement has produced good results. A method for calculating the factor of safety of a pitted shell plate consisting of drawing a profile map of the deteriorated portion and then calculating stresses from the thicknesses of the plate is described. VVK(4)

Weather-OMeter

Serves the Metallurgist

To reproduce the weathering action of years of out-of-doors exposure in a metal or an alloy is a frequent problem of the metallurgist. His specification of what to use for a particular purpose in aeroplane—truck—boat—or a special piece of machinery often depends on his determinations of the weathering limitations of the material.

Again the corrosion action of an acid or alkali in a manufacturing process in machine or product, may demand the attention of the industrial scientist demanding change of the metal used or the composition of the alloy. In these—and many other special treatment problems—the Weather-Ometer has offered a solution of the problem and a measure of the action that no other method made possible.

Weathering action studies on metals—accelerated—controlled—tested—and corrosion factors determined by Weather-Ometer. Ask us for details. Send for Bulletin MA-9.

A New Method of Corrosion Protection of Metal Tubes. (Ein neues Verfahren für den äusseren Schutz von Metallrohren gegen Korrosion.) A. Rocca. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 207.

Refers to an externally applied protection by a mixture of concrete and asbestos on a layer of tar or bitumen. Paper was presented before the International Congress of Mining, Metallurgy and Applied Geology, Liege, June 1930. See also "Protection against Corrosion of Pipes," *Metals & Alloys*, Vol. 2, Jan. 1931, page 2. EF(4)

Evolution of a New Chemical Industry. Lee H. Clark (The Sharples Solvents Corporation). *Chemical & Metallurgical Engineering*, Vol. 38, Apr. 1931, pages 206–210.

Mention is made of the materials of construction used and of the corrosion problems met with in the synthesis of amyl chlorides from pentane and chlorine gas. PRK(4)

Thermal Requirements and Operating Characteristics of the Urea Autoclave. K. G. Clark & V. L. Gaddy (Bureau of Chemistry and Soils, Washington, D. C.). *Industrial & Engineering Chemistry*, Vol. 22, Oct. 1930, pages 1084–1087.

Data are given for the corrosion resistance of a number of metals under operating conditions. In this process of direct synthesis of urea from liquid ammonia and liquid carbon dioxide, the order of corrosion resistance by the metals is Cr, Ta, duriron, Ni, illium G, rezistal 3, Pb, Al, enduro KA, Sn, Zn. MEH(4)

The Influence of Impurities in Soft Lead on its Behavior Toward Acids. (Einfluss von geringen Beimengungen auf das Verhalten von Weichblei gegen Säuren.) Arthur Burkhardt. *Metallwirtschaft*, Vol. 10, Mar. 6, 1931, pages 181–187.

Contains 3 references. 41 commercial grades and alloys of Pb containing small percentages of Cu, Ni, Bi, Sn, Sb, Te, Zn, Cd, Ag, Tl, Fe, Hg or Li, or combinations of these were tested for corrosion resistance against various strengths of H_2SO_4 and HCl at 20°, 90°, 130°, 170° and 220° C. Tensile tests are not a suitable measure as the strength drops in proportion to the reduction in cross section of the test bar. Loss of weight was determined instead. 70% H_2SO_4 at 170° attacks commercial Pb containing Bi, Zn or Ag most, then those containing little or no Cu, and those containing Ni or Cu the least. Cu can compensate for the bad influence of Bi. At 90° Sn, Sb and Ag are no worse than Cu alloys and at 20° there is very little difference between any of the grades. With 98% H_2SO_4 similar results were obtained. Fe, Sb, Sn, Te, Cu and Ni retard corrosion of Pb in H_2SO_4, Tl and Hg have no effect, Li, Ag, Zn, Cd and Bi increase corrosion. Tests were also made in 10% and 20% HCl and in moist Cl_2 at 20° and 90°. In HCl the Cu, Ni and Te containing brands are attacked most and the purest grades least. In 20% HCl the attack is greater than in H_2SO_4, but in 10% HCl it is slight, in moist Cl_2 a little greater. Attempts to obtain greater resistance to HCl by alloying failed. No theory for the effect of impurities on the corrosion of Pb has been worked out, it must be determined empirically. CEM(4)

New Type of Tank Overcomes Corrosion in Aluminum Welds. A. Eyles. *Iron Age*, Vol. 126, Dec. 25, 1930, page 1934.

Observation of Al tanks shows that corrosion usually begins at the welded joints or seams. Tanks for storage of oil and gasoline in aircraft are made from thin tinned steel sheet, riveted and soldered at the joints. New type of tank is designed so that the complete internal surface of tank can be burnished. The tanks were tested far beyond requirements. These tanks are built by Vickery, Ltd., Weybridge, England. VSP(4)

Experiments with Aluminum in Solutions of Soda and Soap. (Versuche mit Aluminium in Soda- und Seifenlösung.) H. Bohner. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 48–49.

The behavior of aluminum in soap and soda solution in the presence of heavy metals is investigated and it is stated that the electrolytic potential law is not generally valid for soda solutions. The addition of sodium silicate entirely prevents the attack of Al at room temperature as well as at 50°–60° C., whether or not Cu, brass or other heavy metals are present in the solution. Ha(4)

Molecular Ray Experiments. The Chemical Activity of Molecular and Atomic Oxygen. Worth H. Rodebush & W. A. Nichols, Jr. *Journal American Chemical Society*, Vol. 52, Oct. 1930, pages 3864–3868.

An exhaustive search failed to discover any surface (metallic Ag, Cu and Na) with which a beam of oxygen molecules will react to give a visible image At slightly elevated temperatures of the metals, a film of oxide is readily visible. Results of tests with atomic oxygen and a reducing action of atomic oxygen are discussed. MEH(4)

Heat Resistivity of Aluminum Steels and Aluminum Coated Iron. (Hitzebeständigkeit von Aluminiumstählen und von Aluminiumüberzügen auf Eisen.) A. Hauttmann. *Stahl und Eisen*, Vol. 51, Jan. 15, 1931, pages 65–67.

Steels with varying contents of Al were heated in air at 1000° C. in an electric furnace. The increase of weight after heating for 48 hrs. at that temperature is taken as an indication of the heat resistivity. The table below gives some of the results, indicating that there is a sudden increase of heat resistivity around 9% Al.

Sample No.	% Aluminum	Increase of Weight g./m.²/h.
1	0.00	45.7
2	1.84	36.2
3	3.72	31.5
4	9.44	0.57
5	22.34	0.29
6	38.32	0.14

The result is related to the structural composition. In Al coating Armco-iron, 2 methods have been used: the calorizing process and the hot-dipping process. Calorizing was done by heating the test bars in a powdered 52–59% ferro-aluminum alloy. In both cases, the life of the coating increases with the thickness of the Al bearing coating. The best results were obtained in calorizing with the 59% ferro-aluminum alloy (300 hrs. at 1000° C.). Calorizing offers advantages inasmuch as even intricate shapes can be coated. At any rate, coatings made with either method offer a remarkable retardation of the oxidation at higher temperatures. GN(4

Development of Adhesives for Foiling. Harry F. Perkins. *Oil & Gas Journal*, Vol. 28, May 1, 1930, pages 31, 103.

The development of adhesives for foiling is discussed. The resistance of various foiling materials to corrosive agencies is given in the following table:

Apparatus for Salt-Spray Corrosion Testing. (Dispositivo per saggi di corrosione.) F. Pietrafesa & O. Romano (Institute of Electrochem. and Electromet. Royal School of Engineering, Milan). *La Metallurgia Italiana*, Vol. 23, Mar. 1931, pages 198–199.

A glass nebulizing nozzle inserted vertically through a paraffined wooden base, carries the salt mist into a glass bell jar, so that the nozzle does not impinge directly upon any specimen. The specimens are supported in bakelite holders symmetrically about the nozzle, and their position need not be changed through the test. The salt solution is drained from the base of the bell jar, discarded if soluble corrosion products are formed, or filtered and returned to the cycle if they are insoluble. The air stream is scrubbed from oil by glass wool, and saturated with water vapor in the usual way. The complete set-up is shown in a photograph. HWG(4)

Examples of Corrosion as Met with in Practice, their Causes and Avoidance. (Korrosionsbeispiele aus der Praxis, ihre Ursachen und Vermeidung.) Karl Mandl. *Mitteilungen des Staatlichen Technischen Versuchsamtes in Wien*, Vol. 19, 1931, pages 48–53.

(1) Al rings as packing in ammonia refrigeration engines had to be replaced by asbestos or similar materials. (2) Cooling coils of Al of different qualities should not be welded together as corrosion can occur. (3) Iron condenser pipes should be galvanized. Lead covered roofing sheets were attacked by the atmosphere in a factory district. An addition of at least 10% Sn to the Pb, or previous tinning before leading, should be applied. Cast iron parts which come into contact with acid liquids must not be used and should be replaced by acid-proof metals or alloys. Ha(4)

Surface Protection of Light Metals. (Oberflächenschutz der Leichtmetalle.) Th. Leib & Fr. Kolke. *Korrosion und Metallschutz*, Vol. 7, Jan. 1931, pages 3–11.

Main viewpoints are given which must be taken into consideration when applying surface protection means. The results obtained with the various paints and lacquers as well as anodic surface protection treatment (Jirotka-Bengough) are collected in tables. Tests were made in which Allautal is submitted to a tempering process. The paper concludes with a critical discussion of accelerated tests of surface protections. EF(4)

The Action of Stationary and Moving Nitric Acid on Aluminum Sheet, Silumin Sheet and Ferrosilicon. (Ueber die Einwirkung ruhender und bewegter Salspetersäure auf Aluminiumblech, Siluminblech und Ferrosilizium.) M. P. A. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 50–51.

The attack on pure aluminum was slightly less by moving acid than by stationary acid. In contact with ferrosilicon, an increased attack could not be stated. Contact with 50% nitric acid results in a loss of 5 g./m.² surface in 24 hrs. Ha(4)

The Corrosion of Iron by Steam at High Temperatures and Its Physico-Chemical Basis. I. (Die Korrosion von Eisen durch Wasserdampf bei hohen Temperaturen und ihre physikalische-chemischen Grundlagen.) W. Krauss. *Korrosion und Metallschutz*, Vol. 7, Feb. 1931, pages 29–34.

A method is described for measuring the rate of oxidation of Fe in superheated steam at high temperatures. The method consists in measuring the increase in electrical resistance of a metal wire during the process of oxidation. The resistance $W = \frac{\varphi \rho_1 \rho_2 L}{\pi}\left[\frac{1}{\varphi r_2^2 \rho_1 + \rho_2 (r_1^2 - r_2^2)}\right]$ in which r_2 and r_1 are radii of the bare wire and the oxide covered wire; ρ_1 and ρ_2 the specific resistances of the metal and the oxide; φ the ratio of molal volumes of the metal and the oxide; and L the length of the wire. Measurements of resistance changes made at temperatures ranging from 500–800° C. and determinations of O_2 in the oxide film showed the ratio of O_2 used to Fe reacting to be approximately that found in Fe_3O_4. Separate determinations of weight increases due to oxidation of Fe in a furnace at the same temperatures were found to agree well with those calculated from the resistance changes. Both methods indicated that the thickness of the oxide layer increased with time according to the diffusion equation $y^2 = kt$ in which y = thickness in μ; t = the time in minutes. The values of k were determined for temperatures of 800, 700, 630 and 600° C. and were respectively 8.08×10^{-6}, 1.57×10^{-6}, 4.22×10^{-7} and 1.27×10^{-7}. Temperature coefficients for the reaction rate were found to be 3%/° C. between 600° and 700°; 1.5%/° C. between 700° and 800° C. (4)

How Quenching Media Affect Corrosion of Alclad Sheets. H. C. Kerr. *Iron Age*, Vol. 126, Dec. 11, 1930, pages 1758, 1821.

From a paper read before the National Metal Congress in Chicago on "Quenching of Alclad Sheets in Oil." Corrosion of duralumin is influenced by quenching medium particularly with reference to corrosion resistance. VSP(4)

Passivity Phenomena in Aluminum in Stationary, Very Dilute Acids and Alkalies. (Ueber Passivitätserscheinungen an Aluminium in ruhenden, sehr verdünnten Säuren und Laugen.) L. W. Haase. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 53–60.

The amount of aluminum dissolved in liquids is of practically no importance. The experiments of the Prussian Institute for Hygiene of Water, Soil and Air resulted in the following values for 1 m.² and 1 yr. and 99.5% pure aluminum: in ordinary drinking water, 230 mg./l.; potassium chloride solutions, 180 to 5200 mg./l. The formation of a protective film often completely prevents a further attack. The purer the metal, the more complete the protection of the film. Amounts of even more than 1 g./l. have no harmful effect on the human system. 26 references. Ha(4)

Basic Phenomena at the Electrolytic Oxidation of Aluminum. (Grundlagende Vorgänge bei der elektrolytischen Oxydation von Aluminium.) H. Ginsberg. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, June 1930, pages 81–84.

The chemical, electro-chemical and electrical processes going on with the oxidation of aluminum are discussed and the formation and solubility of the oxide film investigated. Above 60° C., no effective protective films could be obtained. Ha(4)

Inspection of the Annapolis Corrosion Tests. J. H. Gibboney, *et al.* *Proceedings American Society for Testing Materials*, Vol. 30, 1930, Pt. 1, pages 221–222.

Detailed data on inspection of black sheets of copper-bearing and non-copper-bearing soft steels and open-hearth irons exposed to atmospheric corrosion at Annapolis are given in a table. All failures are in non-copper-bearing materials (less than 0.15% Cu). HWG(4)

Metallography & Macrography (5a)

Manganese a Stabilizer for Austenitic Structure. M. A. Grossmann (Republic Research Corp.). *Steel*, Vol. 87, Oct. 9, 1930, pages 68, 73.

Comment on paper by F. M. Becket on "Chromium-Manganese Steels" presented before the American Iron and Steel Institute. Presents photomicrographs of steels with 18% Cr, 7½% Mn and C content of 0.26%, 0.29%, 0.32% and 0.36%, respectively. Steels were quenched from 2100° F. Structure of first contained a mixture of austenite and ferrite and the steel was strongly magnetic. Structure became more austenitic and the steel less magnetic with increasing C. Last 2 steels had austenitic structure and were almost completely non-magnetic. Role of Mn is to stabilize the austenitic non-magnetic structure, which is first induced by the C. MS(5a)

The Equilibrium Diagram of the Chromium-Carbon System. Kazue Hatsuta. *Kinzoku no Kenkyu*, Vol. 8, Feb. 20, 1931, pages 81–88.

The chromium-carbon system was studied by means of the thermal, microscopic and X-ray analyses and the equilibrium diagram, as shown in the diagram was proposed. In this system there exist four carbide phases, ϵ, η, ζ and κ corresponding to compounds, Cr_4C, Cr_7C_3, Cr_3C_2 and CrC (?) respectively. The crystal form of Cr_4C is cubic, Cr_7C_3 trigonal and Cr_3C_2 orthorhombic, but that of CrC was not determined. α- and ϵ-phases form a eutectic at 1485°, 3.7% C. ϵ- and η-phases are peritectically formed, according to the following scheme respectively: η + melt $\longrightarrow$ ϵ, ζ + melt $\longrightarrow$ η

The peritectic temperature for the former is 1530°, and that of the latter is above 1600°. ζ-phase probably has the maximum melting point on the liquidus curve and forms a eutectic with κ-phase; a transformation takes place at 1505° in this phase. TM(5a)

Dilatometric Investigations in Binary Magnesium-Aluminum Alloys in the Cast State. (Dilatometrische Untersuchungen an binären Magnesium-Aluminium-Legierungen in gegossenen Zustande.) Willi Claus & S. Breisemeister. *Aluminium, Hauszeitschrift der V. A. W. und Erftwerk*, Vol. 3, Jan.-Mar. 1931, pages 40–53.

This investigation was undertaken primarily to discover relations between shrinkage and heat expansion coefficients for pure aluminum and Mg-Al alloys. The diagrams of state are discussed and anomalies of solidification explained. The methods for the measurements of expansion are described, the results illustrated in numerous micrographs and equilibrium conditions of texture discussed. A direct connection between shrinking and expansion cannot be stated. There are 16 references and 2 appendices, one giving the numerical values of shrinkage and expansion coefficients, the other describing an apparatus of quartz-glass for determining the expansion coefficients at high temperatures. Ha(5a)

The AMINCO Automatic Metallographic Polishing Machine

THIS new machine is based upon a similar one, developed by the U. S. Bureau of Standards' engineers, to effect a standardization of methods employed in polishing specimens for microscopic examination. To their design we have added several improvements of our own and can now supply the machine as pictured above, ready for use in the laboratory. It produces a remarkably high polish, free from pits and "comet-tails", such as occur on specimens that are hand polished and showing perfect formation of inclusions, with practically no rounding-off of edges of the cracks. It accomplishes this automatically, polishing three specimens at the same time, without requiring the constant attention of a high-salaried technician. This new machine will very quickly save many times its cost in any metallurgical laboratory. A bulletin describing it in detail will be sent to you promptly, upon request.

Be sure to see us at the Nat'l. Metal Exposition, Boston, Sept. 21st to 25th—at Booth A-16

Equilibrium between Iron Carbide and Iron Oxide. (Sur l'equilibre fer-carbure de fer-oxygene.) M. P. PINGAULT. *Comptes Rendus de L'Académie des Sciences*, Vol. 192, Jan. 5, 1931, pages 45–47.

The author describes very briefly experiments made with a view of obtaining a curve representing the equilibrium of the following reaction, $CO_2 + Fe_3C = 3Fe + 2CO$, at atmospheric pressure. This curve is traced together with those obtained by Boudouard for the reaction $CO_2 + C = 2CO$ and by Chaudron for the reaction $CO_2 + Fe = FeO + CO$. The point of intersection between Pingault curve and that of Boudouard is in the neighborhood of 740° C. and 28% CO_2. Pingault finds the heat of the reaction $CO_2 + Fe_3C = 3Fe + 2CO$ to be −0.5 calorie and estimates the heat of formation of cementite to be −27.5 calories. OWE(5a)

Solubility of Silicon in Aluminum in the Solid State. (Solubilita allo stato solido del silico nell'alluminio.) L. LOSANA & R. STRATTA (Royal School of Engineering, Turin). *La Metallurgia Italiana*, Vol. 23, Mar. 1931, pages 193–197.

Using Al and Si of such purity that Fe ran from 0.02 to 0.04%, Cu about 0.01%, Ca trace to 0.015%, Mg and Na trace, some 20 alloys ranging from 0.03 to 2.88% Si were made up. The solidus and liquidus were determined by thermal analysis. The solid solubility of Si in Al was determined by differential thermal analysis, using a slow rate of cooling, and by dilatometric methods. Rockwell hardness determinations were used to determine the curve from 0.23 to 0.03% Si, the specimens being heated at the rate of 10° or 15° C. per hour to the quenching temperature, held there for 24 hours, and then water quenched. The annealing temperatures ranged from 50° to 400° C. by 50° steps. From the hardness it was concluded that the room temperature solubility of Si lies between 0.07 and 0.1%. The solubility is a maximum at 576° C. and 1.75% Si. The course of the solubility curve from 300° up, as determined by Losana and Stratta, coincides most closely with that of Gwyer and Phillips, the solubility at 500° C. being set at about 0.5% Si instead of about 0.7% (Gwyer and Phillips), 1% (Dix and Heath), or 1.2% (Köster and Muller). Dix and Heath used wrought material, while Losana and Stratta apparently used cast specimens, thus not taking advantage of the use of wrought material in order to obtain equilibrium more readily. HWG(5a)

The Microstructure and the Hardness of Quenched Manganese Steels. TAKEJIRO MURAKAMI & KAZUE HATSUTA. *Kinzoku no Kenkyu*, Vol. 8, Mar. 20, 1931, pages 132–139.

Manganese steels containing less than 12% Mn and 1.2% C were quenched from 900° or 1200° C. in water or oil. From the result of microscopic observation of these quenched specimens, the constitutional diagrams for respective quenching conditions were constructed and the effect of the compositions and the quenching conditions upon the microstructure was demonstrated. The Shore hardness was measured for these quenched specimens and the relation between the hardness and the microstructure, as well as the compositions and the quenching conditions were discussed. The fact that the formation of martensite from austenite is markedly accelerated by quenching stress was shown in many specimens. TM(5a)

A Quantitative Determination of Martensite and Austenite in Quenched and Tempered Steels. K. HONDA & S. SEKITO. *Kinzoku no Kenkyu*, Jan. 1931, pages 8–13.

The method used in the quantitative determination is the same X-ray analysis as described in the foregoing article. Austenitic manganese steel was also treated in the same way. The average intensities of 200 Kα of austenitic manganese steel and of 111 Kα of gold were first compared and then the latter was compared with the intensity of 200 Kα of quenched or tempered steels. In this way the percentage content of austenite or martensite was calculated. The results were as follows: α-martensite having a tetragonal lattice (axial ratio is nearly 1.06) changes completely into β-martensite having a body-centered cubic lattice, in a range 100° to 170° C. The residual austenite changes into β-martensite only slightly up to 200° C., but very rapidly above 200° and this transformation is completed at 240° C. KT(5a)

The Recrystallization of Technical Lead. (Die Rekrystallisation von technischem Blei.) E. LOOFS-RASSOW. *Metallwirtschaft*, Vol. 10, Feb. 27, 1931, pages 161–165.

Contains 4 references. The grain size of 17 grades of Pb was determined after casting them into strips, reducing them 50% by rolling and annealing for 15 hours at 200° C. Electrolytic Pb has a grain size considerably above 1 mm., commercial Parkes Pb about 1 mm. and Pattison Pb and Pb alloys less than 1 mm. Elements like Cu and Ni which are not soluble in Pb reduce its grain size, while Bi, which is soluble, does not. Samples of one of each of the three grades of Pb were reduced from 6 to 87% and annealed at from 18° to 310°. Grain size was determined and recrystallization diagrams constructed. The increase in grain size with rising annealing temperature is gradual for the first two grades, but Pattison Pb hardly changes up to 280°, then suddenly becomes larger than the other two. The lower recrystallization limit is above room temperature for very low deformations, below for higher deformations. There was no difference in the recrystallization grain size of samples rolled at room temperature and at −70°. Long aging of rolled samples at room temperature produces normal recrystallization with higher deformations and grain recovery with low deformations. CEM(5a)

The Molecular Constitution of the η and H Solid Alloys and of the Corresponding Liquid Solutions of the Copper-Tin Series Examined Thermodynamically. F. H. JEFFERY. *Transactions of the Faraday Society*, Vol. 27, Apr. 1931, pages 188–190.

The solid η is the definite compound Cu_3Sn but the liquid phase is Cu_4Sn dissolved in monatomic tin molecules. The thermodynamic method also shows that if the liquid phase is Cu_4Sn in monatomic tin molecules, the solid phase H is a solid solution of Cu_3Sn in monatomic tin molecules. PRK(5a)

Practical Use of the Knowledge of Structure of Steels. (Utilidad practica del conocimiento estructural de los aceros.) F. GONZALEZ V. *Revue Quimica*, Vol. 6, July 1930, pages 21–25.

Based on the chemical composition of the steel an attempt is made to calculate all the structural phases existing in steel such as free pearlite, Mn_3C, MnS, Fe_3P and free ferrite. Juptner, Neil and Osmond formulas have been used in calculating tensile strength, hardness and elasticity. GTM(5a)

Practise Exercises in Metallography. (Travaux pratiques de metallography.) W. BRONIEWSKI. Translated from Polish into French by G. Pruszkowki. Preface by H. Le Chatelier. Dunod, Paris, 1930. Paper, 6¾ × 9 inches, 110 pages. Price 28.50 Fr.

This laboratory instruction book in metallography outlines exercises in metallographic examination, with reference to equilibrium diagrams of the alloys studied; deep etching; recognition of inclusions; thermal analysis; effect of quenching and tempering; carburization; annealing of cold worked alloys; pyrometry; hardness testing; and welding.

Sketches are shown for the set-up of each experiment and the technique of, and the interpretation of, each type of examination are discussed. Going through such a course under a good instructor would be good training for the student. The pamphlet is of special interest as showing the type of instruction in metallography that is given abroad.—H. W Gillett (5a)-B-

FOR THE ANALYSIS OF CRYSTAL STRUCTURE OF MATERIALS

The *Keleket Type "A" Diffraction X-ray Apparatus* consisting of an especially designed High Tension X-ray Transformer, Stabilized Filament Transformer, X-ray Control Unit, CLARK-HAYES Oscillating Spectrograph Camera, and Auxiliary Equipment.

A B C

A group of diffraction patterns of cast steel:

"A" the pattern of steel as it came from the mold;
"B" the pattern of steel after 5 hours annealing;
"C" the pattern of steel after 20 hours annealing.

"A" shows many strains, "B" less, and "C" shows practically all strain removed with consequent random orientation of crystals.

***Keleket* is a symbol of X-ray development. Almost ever since its discovery, Keleket engineers have been associated with, and largely responsible for, X-ray Progress. Many of the major improvements may be traced to the pioneering spirit of the men in the Keleket Laboratory.**

Yet modern production methods enable us to place Keleket excellence upon the Industrial Market at a price that means buying economy.

There must be some reason why the leading X-ray Specialists of the nation use Keleket X-ray equipment exclusively—if you are X-ray minded—investigate.

Structure & X-Ray Analysis (5b)

Non-Destructive Testing of Metals—Present and Future. ANCEL ST. JOHN. *Iron Age*, Vol. 127, Jan. 1, 1931, pages 54–55.

The ability to distinguish between permissible and non-permissible defects is the rock upon which non-destructive test methods have failed. Non-destructive tests will develop along two lines. One will be concerned with distinguishing normal material from abnormal. The other will be directed to distinguishing abnormal material which is permissible from that which must be rejected. VSP(5b)

Three Crystalline Modifications of Electrolytic Chromium. KUMAZO SASAKI & SINKITI SEKITO. *American Electrochemical Society, Preprint* 59–25, April 1931 meeting, 7 pages; *Journal Society of Chemical Industry*, Japan, Vol. 33, Nov. 1930, pages 482B–485B.

X-ray spectra were made of chromium electrodeposited from acid chromic sulphate solutions. At current densities below 15 amp./dm.^{2} the body-centered cubic form is deposited; above 18 amp./dm.^{2} the hexagonal close-packed form; and at intermediate current densities both the cubic and the hexagonal modification are deposited. The effect of bath temperature is very apparent. At 20° C. or below the hexagonal form was obtained; at 26° C. the body-centered cube only. Chromium plates made from chromic acid baths were always cubical with a lattice constant equal to 2.877 ± 0.003 A. U. The hexagonal modification is gradually transformed into the cubic even at room temperature. MB(5b)

The Determination of Crystallite Orientation. G. TAMMANN. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 29–73.

See *Metals & Alloys*, Vol. 1, Dec. 1930, page 908. (5b)

The Constitution of the Cadmium-rich Alloys of the System Cadmium–Silver. P. J. DURRANT. *Metal Industry*, London, Vol. 38, Apr. 17, 1930, pages 403–406, 415.

Paper given at Institute of Metals, March 11–12, 1931. See *Metals & Alloys*, Vol. 2, May 1931, page 97. PRK(5b)

Lattice Distortion as a Factor in the Hardening of Metals. WM. L. FINK & KENT R. VAN HORN. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 241–254.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. (5b)

The X-Ray and Welded Structures. H. R. ISENBURGER. *Welding*, Vol. 2, Apr. 1931, pages 229–231.

A brief enumeration of the advantages of this method of testing without destroying or impairing the test piece. Some practical arrangements for making exposures are illustrated. Ha(5b)

The Lattice Constants of the Gold-Silver Alloys. (Die Gitterkonstanten der Gold-Silberlegierungen.) G. SACHS & J. WEERTS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 109–113; *Zeitschrift für Physik*, Vol. 60, 1930, pages 481–490.

Precision measurements of the lattice constants of Au-Ag alloys give:

% Ag.	Observed Constant A. U.	Calculated Constant A. U.
0	4.0700	4.0700
2.0	4.0692	4.0694
4.9	4.0686	4.0687
6.1	4.0690	4.0685
19.9	4.0674	4.0672
35.5	4.0678	4.0678
49.9	4.0693	4.0694
59.9	4.0708	4.0708
65.3	4.0722	4.0717
84.8	4.0744	4.0750
89.6	4.0760	4.0758
94.5	4.0766	4.0766
100	4.0777	4.0777

The calculated values are from the parabolic formula

$$a = K \cdot A_{Ag} + (1 - K)A_{Au} - 0.0240K(1 - K)$$

where K is the atomic fraction of Ag. The deviation from a straight line relationship is very great. For instance, at 50 atomic % (35.5% by weight) the constant on the straight line assumption would be 4.0739 instead of 4.0678. HWG(5b)

The Orientation of Single Crystals Obtained Through Recrystallization. (Die Orientierung einzelner durch Rekristallisation gewonnener Kristalle.) G. SACHS & J. WEERTS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 92–94; *Zeitschrift für Physik*, Vol. 59, 1930, pages 497–500.

The orientation of the large crystals of Al and its alloys decidedly favors the face diagonal [110] if the content of impurities is small. But in the presence of impurities, the cube edge [100] and the cube diagonal [111] are favored, and as Si increases, the cube diagonal is chiefly favored, as shown in the following table for an alloy with 5% Cu.

Si %	Fe %	% Near [111]	% Near [100]
.25	.27	91	9
.34	.29	81	19
.35	.34	59*	35*
.38	.29	41	59

* 6% in intermediate positions.

Plots are shown for the observations on which this table is based; also, for Al of various degrees of purity. HWG(5b)

X-Ray Investigation of Cementite Obtained by Tempering Quenched Steels. SINKITI SEKITO. *Kinzoku no Kenkyu*, Japan, Jan. 1931, pages 1–7.

The quantitative determination of the cementite obtained by tempering quenched steels was carried out by X-ray analysis. Quenched specimen 5 mm. in diameter was put at a point 2.5 mm. from the center of the Debye-Scherrer camera. A thin gold film 4.6 mm. wide and 0.04 mm. thick was longitudinally wound on a part of the surface of the specimen, so that the spectral lines of gold and cementite were given in the same film. Putting the intensity of the gold line as a standard line of reference, the intensity of the cementite line was compared. Seven Swedish steels of 0.2 to 1.4% carbon were investigated and the following results were obtained: the intensity of the spectral lines of cementite in annealed steels is proportional to the content of carbon. The spectral lines of cementite in quenched steels begin to appear by tempering at about 300° and attain their full intensity at 550° to 600° C. By a prolonged heating at 300° to 400° C., the cementite molecules precipitated from martensite build up crystals characteristic of cementite, and consequently the spectral lines of cementite become detectable. KT(5b)

X-Ray Inspection of Welds in Pressure Vessels. ANCEL ST. JOHN. *Iron Age*, Vol. 126, Dec. 18, 1930, pages 1828–1832.

X-rays are produced when electrons, traveling at high speed in an exhausted bulb, strike a heavy target of W placed at the center of the bulb. The X-rays are passed through wall of the vessel including welded seam. Cavities, cracks and inclusions appear as dark regions on print. X-ray equipment was installed at Barberton, Ohio, for Babcock and Wilcox Co. Describes apparatus installed and method of procedure. VSP(5b)

Section of die-cast aluminum alloy. The radiograph shows clearly the defects due to blowholes.

Let Radiographs prove their value to you

THE industrial uses of the x-ray are increasing with astonishing speed. The proof of the value of inspection of materials by means of radiographs has resulted from problems submitted to us by manufacturers. If you, too, have a material problem to submit to the x-ray, our laboratory facilities are at your service.

As a preliminary, write for a copy of "Industrial Application of the X-Ray"—a recently published booklet which describes and pictures some of the many uses to which the x-ray has been put by modern industry. The coupon, filled in, clipped and mailed, will bring you this booklet free. Mail it today.

New Precision Hydraulic Universal Testing Machine

This new testing machine of the Riehle Bros. Testing Machine Co. is built in three distinct units; the Loading Unit, the Indicating Unit and the Power Unit.

Loading Unit—This part of the machine has the customary upper and lower heads in which are the grips for tension testing. The upper head rests on four rods attached to the table while the lower head is sustained by two large screws set into the base of the machine. Bronze nuts in this lower head, rotated by a motor and worm drive, serve to move the head up or down for adjustment. This drive is never used for testing.

The table is supported on the ram, which with its cylinder is housed in the base casting. When hydraulic pressure is applied to the ram it lifts the table and with it the upper head. As the lower head is stationary, it is evident that a specimen gripped in the upper and lower heads will receive a tensile load while one placed between the table and lower head will be loaded in compression. The ram and cylinder are ground to a fit of such precision that no packing is required to hold the pressure.

A slight leakage maintains a film of oil between the surfaces of the ram and cylinder and practically eliminates friction. The hydraulic pressure in the cylinder is, therefore, a function of the load on the specimen and affords an accurate and dependable means of measuring that load.

The Gripping Mechanism—The gripping mechanism is claimed to be the most striking innovation in the loading unit of the machine. The grips themselves are of the familiar wedge type, but where the usual type grips must be moved up or down to seize the specimen, these grips move horizontally until they engage. When the specimen is strained they then slip on inclined surfaces as in the usual type, so as to maintain their hold on the specimen.

Gripping and releasing is accomplished by turning a small crank handle. No liners are required and no part of the mechanism extends above or below the head.

Weighing Unit—Pressure from the main cylinder is brought through a transfer valve so that it may be applied, at the will of the operator, either on one plunger working singly or on two plungers working in opposition. These plungers are also of the unpacked or floating type and are oscillated rapidly by an individual motor drive so that friction effects are entirely eliminated. Whether one plunger is working alone or both plungers opposed, the resulting effort is counterbalanced by the buoyant effect of a steel float in a pool of mercury.

The sizes of the float and of the mercury container are so chosen that a small motion of the float produces a relatively large change in the mercury level. This results in a very sharply marked equilibrium point which not only makes for accuracy but also completely prevents surging in the event of rapid change of load.

When the single plunger is working, the hydraulic pressure on its cross-section area at one-fifth the total capacity of the machine is sufficient to submerge the float its full depth. When the two plungers are working in opposition it requires the full capacity pressure to submerge the float its full depth. This arrangement obviously affords a simple and direct means of obtaining full scale load indications either at full capacity or one-fifth capacity as desired.

The travel of the float is transmitted through a rack and pinion to a pointer moving across the face of a twenty-inch dial. The pointer actuating mechanism is very simply and ruggedly constructed.

Owing to the relatively large forces employed in the float assembly it is possible to use heavy construction in the indicating mechanism without loss in sensitiveness, thus insuring long service with little or no maintenance cost. The dial face itself is graduated and marked for both full and fractional scales so that both are always available. Changing from one to the other involves only the manipulation of the transfer value which can be accomplished in a few seconds. A maximum pointer is provided and the whole dial face closed by a plate glass cover to protect the dial and pointer from injury.

The indicating unit, in addition to its primary function, serves as a mounting for the necessary electrical and hydraulic controls. Immediately under the dial is the single pump control lever. This enables the operator to regulate the flow of oil with the utmost sensitiveness and accuracy. On the left side is the push button station controlling the pump motor and immediately adjacent to it is the double throw switch for running the lower head up or down. On the right is the transfer valve for charging the load indicating scale and immediately above it is the knob for adjusting the pointer to zero.

Power Unit—This is located directly in back of the weighing unit. The pump is a six-plunger variable stroke high-speed pump mounted in the oil tank and driven by a constant speed motor through a chain transmission. The flow of oil is continuous and regular without pulsations. The delivery is regulated by a cam, operated by the control levers on the front of the weighing unit, which adjusts the stroke as desired. When in the "off" position, a further motion of the cam opens a discharge valve which permits the load plunger to return to its starting point. All oil entering the pump passes through a filter which effectively prevents the entrance of dirt or chips into the system.

One Good Method of Eliminating Overhead

Under present conditions it is refreshing to know that at least one manufacturer has solved his business problems, by a novel method of buying, manufacturing and marketing. He is unconcerned about fixed charges, frozen assets and the much discussed bugaboo of overhead. In fact, his gross and net profits have so much in common that one would hardly question the success of his business procedure. This manufacturer is Mr. P. Haleen, tool maker of 10047 Wentworth Ave., Chicago. He buys his steel, makes his tools and sells them, all in one day, giving the industrial world something to shoot at in the way of quick turnover. It must be mentioned that Haleen takes his tool shop with him and manufactures his products on the way to market.

The above photograph was taken of Haleen's traveling tool shop in front of the plant of Joseph T. Ryerson & Son, Inc. where he visited recently to obtain two 12 ft. bars of $^3/_8$ inch shafting, cut in 2 ft. lengths. The twelve short bars were rapidly transformed into one dozen rim wrenches, ready for sale shortly after the steel had cooled. Facilities for forging, punching and bending may be seen on the trailer.

This nomadic business is not limited to the manufacture of rim wrenches, but supplies the market with chisels, punches, bending bars and body straighteners as well. Entirely free of administrative and production problems, Haleen may concentrate his efforts on building up a substantial sales volume.

Calendar of Meetings

International Foundry Exhibition and Congress, Milan, Italy, Sept. 12–27.

National Metal Congress and Exposition, Hotel Statler, Boston, Mass., week of Sept. 21.

American Welding Society.
Institute of Metals Division, A. I. M. M. E.
Iron and Steel Division, A. I. M. M. E.
Machine Shop Practice Division, A. S. M. E.
Iron and Steel Division, A. S. M. E.
American Society for Steel Treating.

American Gas Association, Atlantic City, N. J., Oct. 12–16.

National Safety Council, Chicago, Ill., Oct. 12–16.

Third International Conference on Bituminous Coal, Pittsburgh, Pa., Nov. 16–21.

American Institute of Chemical Engineers, Atlantic City, N. J., Dec. 9–11.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

The Effects of Two Years' Atmospheric Exposure on the Breaking Load of Hard-Drawn Non-Ferrous Wires. J. C. HUDSON. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 409–431.

Includes discussion. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 909. (6)

Fatigue Properties of Welds. J. B. JOHNSON. *Welding*, Vol. 2, Mar. 1931, pages 159–163.

Describes some fatigue tests with results, from which it is concluded that the removal of the bead has little effect on a butt-welded seam on large parts but a considerable effect on small pieces about $^3/_4$ in. in diameter. Heat treatment such as annealing or normalizing will raise the fatigue limit. Improvement in welding technique which reduces the number and size of the oxide particles and blow-holes will also raise the fatigue limit. 6 bibliographic references. Ha(6)

"Pendulum" Hardness Tests of Commercially Pure Metals. D. A. N. SANDIFER. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 115–148. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 846. (6)

Instrument for Measuring Thickness for Continuous Testing of Thin Wires. (Ein Dickenmessgerät zur fortlaufenden Prüfung dünner Drähte.) SAMSON. *Elektrotechnische Zeitschrift*, Vol. 52, Apr. 16, 1931, pages 512–513.

The wire (for instance thin wires as used in filaments for incandescent lamps) is drawn through a pair of jaws one of which is movable and connected to one of two condenser plates so that the plate is moved when the thickness of the wire changes. The tiny movements of the condenser plates change the capacity of the condenser and as the latter is made part of an oscillatory circuit the change is translated into sound or it can also be recorded. A change of thickness of 1×10^{-4} mm. showed a deflection of the instrument of 0.8 mm. Ha(6)

Strip Steel for Razor Blades Is Tested Magnetically. H. R. SIMONDS. *Steel*, Vol. 87, Oct. 30, 1930, pages 51–53.

Auto Strop Safety Razor Co. has installed equipment for electromagnetic testing of strip. Unit consists essentially of 3 step-down transformers so arranged that any 2 may be electrically opposed and the current differential from the secondary winding measured on an oscillograph. Specimens to be tested are placed within the windings of the transformers to serve as cores. Differential oscillogram offers accurate comparison of specimens and by using a known standard in one coil it is possible to determine accurately such characteristics as microstructure, C segregation, defects, heat-treating results and C content. Transformers are mounted on a table about the size of an ordinary desk, and suitable switches and instruments are mounted near them. Oscillograph is in a separate dark room. Normally the oscillogram appears as a white line on a frosted glass surface. Some sample curves show the decrease in permeability due to an increase of 40° F. in quenching temperature, and the increase in permeability due to 80° F. increase in drawing temperature with quench temperature constant. Strip used is a Swedish annealed steel containing 1.25% C, 0.25% Cr, and less than 0.04% combined P and S. Magnetic tests are made before and after hardening. Manufacture of blades is by the continuous method. MS(6)

Weld Defects Are Detected by Stethoscope Tests. *Steel*, Vol. 87, July 24, 1930, pages 46–47.

Influence of Structure and Composition, Especially Phosphorous Content, on Wear Resistance of Cast Iron. (Einfluss des Gefügezustandes und der Zusammensetzung von Gusseisen auf die Verschleissfestigkeit, mit besonderer Berücksichtigung des Phosphorgehaltes.) T. KLINGENSTEIN. *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns*, Vol. 1, Sept. 1930, pages 18–24. 4 references.

A Hanfstaengel bearing testing machine was reconstructed into a wear test machine of the Spindel type. The specimen is pressed onto a rotary steel disk, apparently about 10 cm. diameter and of 5 mm. face, moving at 400 R. P. M. under a pressure of 5 kg. The depth of the groove cut into the cast iron specimen in 1500 R. P. M. of the disk is taken as a measure of wear-resistance. The size of the specimen and disk are not clearly stated. The specimens were cut from 1.2 in. diameter × 6 in. high bars cast upright. No data are given on the wear upon the steel disk. Using cast irons of 3.16. to 3.62% total C, 0.40 to 0.95% combined C, 1.74 to 2.72% Si, 0.73 to 1.06% Mn, 0.03 to 0.15% S, and with P varying from 0.09 to 1.89%, it was concluded that the wear resistance of cast irons with a ferritic ground mass increased about 100% as the P increased from 0.25 to 0.70%, thereafter increasing but slightly with higher P. At 0.70% the phosphide net work was quite continuous. With a pearlitic ground mass, the wear resistance was as good with low phosphorus as at 0.70% P in ferritic irons. Thin, long, graphite flakes are more desirable for wear resistance than thick short ones that break up the continuity of the ground mass. The wear resistance of irons of about 2.95% total C, 0.85% combined C, 1.75% Si, 0.70% Mn, 0.40% P, 0.10% S, was about the same as that of several Ni-Cr irons with 3.15–3.30% total C, 0.90–0.95% combined C, 0.80–0.95% Mn, 0.35% P, 0.10% S, and 0.45% Cr, 0.90% Ni or 0.75% Cr, 1.4% Ni. Wear resistance is not necessarily proportional to hardness. HWG(6)

The Bending Test for Aluminium Sheet. *Metal Industry*, London, Vol. 37, Aug. 29, 1930, pages 193–195.

The mechanical tests were made on Al sheet including: tensile strength, hardness, cupping values and bending values. Bending test is a useful indicator of the workability of sheet. Describes temper classification used for Al sheet. Sheet tempers for Al in British and American practice are:

American	British
2SO	Soft
2S2	Medium soft
2S4	Half hard
2S6	—
2S8	Medium hard
2SH	Hard

Using bend test, it is advisable to choose at least the next softest temper so as to allow a factor of safety for variation in run-of-mill production. Bending tests may also be used for tubes, rods and flat sections. Tabulates results of bending values of commercial sheets. VSP(6)

Elastic Measurements on Copper with a Martens' Mirror. (Elastische Messungen an Kupfer mittels Martensscher Spiegel.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 14, 1930, pages 3–7; *Messtechnik*, Vol. 4, Sept. 22, 1928, pages 231–236.

Refined measurements of copper which has been cold-stretched to various percentage extensions and then aged or heated to 100° C., indicated, by hysteresis and proof-loading tests, that the coefficient of elastic extension (reciprocal of the modulus of elasticity) may be considered as made up of one factor which decreases steadily as the degree of cold-stretching increased, and of another factor, due to the internal stress produced, the second factor increasing with the amount of cold work. The sum of the two factors makes the coefficient of elastic extension have a maximum, but at a rather small amount of cold work, since the internal stress increases rapidly at first, then more slowly as the amount of cold work is increased. Hook's law is not really obeyed, but is only a limiting case approached when the degree of cold-stretching is sufficiently great. The modulus of elasticity is different at every different load in fully annealed copper. Between the fully annealed and the severely cold worked states there is no true modulus; it varies with the load and with the previous history of the specimen. The purity of the copper used is not stated. HWG(6)

SCHOPPER

METAL TESTING MACHINES

For tensile, compression, transverse, shear testing, etc.

For rods, bars, sheet metal, wires, springs, etc.

Model 4012 Schopper Tensile Tester
Maximum Capacity 1000 lbs.

Pendulum load indicator for full, half and one-fifth loads.

Capacities up to 20,000 lbs.

Motor driven for three speeds. Also special hydraulic device for continuous speed changes.

Schopper Impact Tester
(Charpy Type)

Impact Testers

Both Charpy and Izod with or without impact tensile testing device.

Capacities up to 120 foot/lbs.

Can also be equipped for two load ranges.

TESTING MACHINES, INC.
314-316 Broadway NEW YORK

"Alpha" Hardness Tester for Steel. (Le durometer "Alpha.") RAYMOND SANCERY. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Apr. 1930, pages 183–186.

This apparatus is used to test the exact hardness of quenched steels. The diamond has an angle 120° and is applied with an initial load of 10 kg. This load is progressively applied to a final load of 150 kg. This tester

resembles the Rockwell machine, and in order to get the Brinell hardness the diamond point is replaced by a steel ball. A graph is given showing the relation of Alpha, Brinell and Rockwell hardness numbers. GTM(6)

Apparatus for Measurement of the Change in Cross Section of Loaded Bars. (Apparat zur Messung der Querschnittsänderungen belasteter Stäbe.) H. SIEGLERSCHMIDT. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 14, 1930, pages 22–27.

An instrument of the Martens' mirror type for measurement of the change in diameter of a tensile test bar, sensitive enough to be suited for use in determination of Poisson's ratio. The method of calibration is described. Determinations agreed within 3/1,000,000 in. or less, on steel specimens ranging from about $^1/_2''$ to $1^1/_2''$ diameter. All determinations on any of the bars, at any load from 570 to 5700 lbs./in.², showed Poisson's ratio within the limits 0.289 and 0.292. HWG(6)

Determination of Mechanical Properties of Steel. R. L. TEMPLIN. *Proceedings of Engineers' Society of Western Pennsylvania*, Vol. 46, Dec. 1930, pages 313–321; discussion 321–326.

Relationships between mechanical properties are first discussed, and then the methods for determining the properties, under which standardization is emphasized, as well as the recognition of the statistical element. Under testing machines and apparatus, the author deplores the fact that there are instruments which so far appear to be capable of merely testing a specimen without giving results of generally recognized significance or usefulness, and he gives numerous bits of advice in connection with selection, installation and operation. The discussions centered about the relationships between properties. MFB(6)

Changes in Electrical Conductivity in Strong Magnetic Fields. (Die Aenderung der metallischen Leitfähigkeit in starken Magnetfeldern.) H. J. SEEMANN. *Zeitschrift für Metallkunde*, Vol. 22, July 1930, pages 246–247, bibliography.

A critical discussion of the investigations of Kapitza on the changes in electrical conductivity of metals in varying magnetic fields up to 300,000 Gauss. EF(6)

The Bridge Methods of Testing Welds. J. R. BATCHELLER. *Welding*, Vol. 2, May 1931, pages 308–312.

Describes the X-ray and magnetic testing method used by the Babcock & Wilcox Boiler Works for testing boiler welds. Ha(6)

Critical Review of the Magnetic Methods for Testing Materials (Magnetic Analysis). (Kritische Betrachtung der magnetischen Verfahren zur Werkstoffprüfung [magnetische Analyse].) ERICH GEROLD. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 2, No. 2, 1931, pages 23–37.

A discussion of methods used in the field of practical shop-testing of materials up to the middle of 1930, with special reference to work done in America. At first, the magnetic quantities are defined and it is shown how the physical properties of a material determine its magnetic conditions and how, by measuring the latter, defects in the material such as cracks, segregation, pipes, etc., can be determined and located. These magnetic methods are particularly superior to other test methods since they do not destroy the piece so that eventually every piece in any stage of fabrication can be tested. That these methods have not found the widest use is due very often to inconvenience in arranging the apparatus in the shop, especially for quantity testing. The several principles of magnetic testing are described with the instruments developed for this purpose; methods measuring the magnetic leakage, induction methods and saturation methods. Applications for testing of rails, pipes, ingots, welding seams, welds, wire ropes, turbine discs and hollow bodies are illustrated. A list of 66 bibliographical references is added. Ha(6)

Influence of Magnetic Fields upon the Mechanical Hardness of Alloys. (Beeinflussung der mechanischen Härte von Legierungen durch Magnetfelder.) E. G. HERBERT. *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 126–127.

Influence of magnetic fields upon changes in hardness of steel and duralumin is discussed. EF(6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A. S. T. M. Research Committee on Fatigue of Metals.

Effects of Annealing on Chains. H. A. THOMAS (Carnegie Institute of Technology). *Transactions National Safety Council*, Vol. 1, 1930, pages 281–332. Includes Discussion.

Embrittlement of chain due to development of a cold worked skin, resulting in danger of failure under impact loading was discussed by Gough and Murphy for wrought iron chain in Engineering Research Rept. No. 3, British Dept. of Scientific Industrial Research 1928. They concluded that failure was not due to true fatigue. Similar studies were made by Thomas on soft steel chain stock. Instead of making true endurance tests, repeating overstressing loads were used which would cause failure in some 200,000 cycles. The original chain stock had a tensile strength of 48,000 lbs./in.² Under rotary bending stress of ±26,800 lbs./in.² failure occurred at 205,000–220,000 cycles. Annealing at 1500° F. for 30 min. followed by air cooling, on new specimens gave failures at from 156,000 to 252,000 cycles, averaging 175,000; if the scale was filed off, lives of 124,000–297,000 were obtained. If the specimens were first stressed for 100,000 cycles and then annealed, failures occurred in 1700 to 190,000 additional cycles. Annealing evidently does not heal the incipient fractures caused by overstress above the endurance limit. New specimens surface-hardened by hammering, increased in endurance resistance, lives of 228,000 to 1,147,000 cycles, averaging 600,000, being obtained. Failure of chains from presence of a work hardened surface is therefore not due to fatigue. Various impact and other tests for brittleness on steel and wrought iron chain links, surface hardened by mutual wear in use, or by a special laboratory set-up showed marked decrease in brittleness after annealing. Repeated load tests were made on chains as well as on chain stock. To remove danger from work-hardened surfaces it is recommended that wrought iron chain be heated to 1350–1375° F. and steel chain to 1600–1650° F. followed by air-cooling. Time at temperature should be $^1/_4$ hour for $^1/_4''$ to $^1/_2''$ chain, $^3/_4$ hour for $^1/_2''$ to $1''$, 1 hour for $1''$ to $1^5/_8''$ and 2 hours for over $1^5/_8''$. Pyrometric control should be used. The annealing or normalizing of steel chains or the removal of strain from wrought iron chains in this way does not remedy damage caused by repeated overstrain, but it removes embrittlement due to the work-hardened surface, which is the most serious cause of failure. HWG(6)

Fatigue Tests of Acetylene Welds. (Ueber Dauerprüfungen von Azetylen-Schweissungen.) BAUMGAERTEL. *Autogene Metallbearbeitung*, Vol. 24, Mar. 15, 1931, pages 81–87; Apr. 1, 1931, pages 96–99.

Exhaustive tests were made to compare the resistance of welds for continuous bending stresses with that of the solid material. The various methods and apparatus for such tests are described. Some of the results are given in the following table where λ is the ratio of the strength of the welded material to the solid material and φ is the ratio of the strength of the welded material to the tensile strength of the normal material:

	Tensile strength kg./mm.²	Fatigue bending strength (not welded) kg./mm.²	λ %	φ %
Norwegian welding wire	42.3	9.15	40.6	21.6
Mild steel wire	39.8	11.25	50.0	28.3
Vanadium steel wire	40.4	9.85	43.7	24.4
Chromium-molybdenum wire	41.8	5.62	24.95	13.4
Norwegian welding wire (bulge filed off)	37.6	11.95	53.1	31.8
Norwegian welding wire	35.5	16.85	74.9	47.5

Other tests with Cr-Mo pipes gave a ratio of λ of 55.8 to 64%. The author concludes that there is no doubt a fatigue limit in acetylene welds which is greatly influenced by the care with which the weld is made. Ha(6)

Determination of Endurance Limit of Nickel-Copper Alloys by Measuring Electric Resistance. S. IKEDA. *Kinzoku no Kenkyu*, Jan. 1931, pages 32–41.

The author's short time method of determining endurance limit of steels was applied to an annealed Ni-Cu alloy which forms a continuous solid solution. Electric resistance in specimens subjected to repeated bending stress was measured for different increasing stress. Up to a certain value of the applied stress, the electric resistance remained constant and afterward increased gradually; but the stress at which the resistance began to increase was quite distinct from and a little below the proportional limit of the static tension test. This stress may be considered the true endurance limit just as in the case of steels which consist of a minute mixture of cementite and ferrite. The constituent-endurance limit diagram suggests that a specimen containing about 65% Ni has the maximum endurance limit. The relation between the hardness number (sceleroscope, Brinell and Rockwell) and the endurance limit determined by electrical method or the specific resistivity may be represented by loop or a part of loop instead of a straight line as in the case of steels. KT(6)

Endurance Testing with the M. A. N. Repeated Bending Machine. (Erfahrungen über die Prüfung der Dauerfestigkeit verschiedener Werkstoffe auf der M. A. N. Biegeschwingungsmaschine.) A. JÜNGER (Maschinenfabrik Augsburg-Nürnberg). *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns*, Vol. 1, Sept. 1930, pages 8–18. 13 references.

The bulk of the endurance testing has been done on Wöhler-type machines. In spite of all the attempts at accelerated test methods that have been put forth, none is satisfactory. The disadvantage of the Wöhler method is the time required The M.A.N. machine takes a flat specimen, about 0.6″ wide, 0.2″ thick, and 6″ in the test section. By means of a magnet the specimen is vibrated in reversed bending some 2200 to 4100 cycles per minute. Jünger gives tests on some 2 dozen steels from which he calculates that for a polished specimen the formula $\frac{1}{5} \times$ (Tensile strength + yield point, both in metric units, + percentage reduction of area) gives the endurance limit within ±10%. The only non-ferrous material for which he gives the yield point is duralumin. The formula is not applied to this, nor does it give the endurance limit when one figures it out for a specimen tested in the longitudinal direction. The strongest steel included in Jünger's table is one of 145,000 lbs./in.² and no tests are presented to show how his formula works out on, say, a quenched alloy steel tempered at a low temperature. He advises direct endurance tests in preference to calculation, but finds the calculation helpful in choosing the test stress. Some comments and data are given on effect of rough machine finishes, scratches, corrosion and welding. The figures for endurance limits are about the same as are usually obtained for similar materials on other testing machines. The only ones of especial interest are for cast iron, as follows:

	C	Si	Mn	P	Bending lbs./in.²	Deflection in.	Tensile lbs./in.²	Brinell	Endurance Limit lbs./in.²
Ordinary	2.97	1.22	0.43	0.60	61,000	0.34	36,000	209	20,000
High Test	2.90	1.20	0.95	0.23	81,000	0.45	49,000	193	19,000

in which the endurance does not go up with the tensile strength. The ordinary iron had as fine graphite as the other HWG(6)

The High-Temperature and the Notched Endurance Limits of Some Ferrous Materials. (Ueber die Dauerbiegefestigkeit einiger Eisenwerkstoffe und ihre Beeinflussung durch Temperatur und Kerbwirkung.) EGON KAUFMANN. Julius Springer Verlag, Berlin, 1931. Paper, 6¼ × 8¾ inches, 89 pages. Price 9 RM.

A rotary bending Schenck endurance machine was provided with attachments for carrying out "accelerated" tests according to the method of Lehr. The deflection of the specimen under load, the torque exerted by the driving motor and the temperature rise of the specimen are all measured in this method. In order to apply the rise of temperature method at temperatures above that of the room, a hollow specimen was made, 0.42 in. outside diameter in the breaking section and a 0.2-in. hole drilled (before heat-treatment) axially through the specimen. A thermocouple was inserted at the center of the specimen in a holder carrying two slip rings to which the elements of the couple were connected. The couple and holder rotated with the specimen. Flexible copper brushes contacting with the slip rings connected the thermocouple to the galvanometer circuit.

The specimen was surrounded by a heating coil so that elevated temperature endurance tests could be made. The length of the cylindrical breaking section of the specimen was 0.4 inch. At 300° C. the temperature 0.2 inch from the middle of the specimen was 3° C. low, at 700° C., 7° C. low. The temperature of the outside of the specimen at the point of maximum load was not determined. The machine was run at 3000 R. P. M. Disks of sheet metal, 3½ in. diameter, 0.008 in. thick, rotating with the specimen were interposed between the heating furnace and the machine bearings. No other cooling of the bearings was required.

On the plots of the accelerated tests are shown three stresses, the first corresponding to the first, ill-defined knee in the temperature-rise curve, rarely to any definite knee in the torque curve of the motor dynamometer and never to any detectable knee in the deflection curve. The second is on the whole somewhere near to a change of direction in the torque curve, to one in the temperature-rise curve, and more or less in the neighborhood of a very slight change in the deflection curve. By dint of looking at all three curves, it is usually possible for the author to mark off a stress, "Sigma 2," that is supposed to correspond with the endurance limit in a real endurance test, but the exact position is often pretty much of a guess.

Actual endurance tests were then made and the endurance limits and the "Sigma 2" limits plotted for the various temperatures. On cast iron the curves coincide up to 500° C., the highest temperature at which actual endurance tests were made on the iron. On the two carbon steels the endurance curve is considerably above the accelerated test curve, while on the heat treated Ni-Cr steel it is considerably below it. The results do not indicate any particular utility for the accelerated methods.

The endurance tests, even at the highest temperatures, were not run to more than 10 million cycles (save for one bar of cast iron) and in several cases only 3 or 4 specimens were run. On the Ni-Cr steel at 400° C. there was no stress used between 71,000 and 63,000 lbs./in.²

The accelerated test results do not appear worth repeating. The endurance limits give the following data:

Materials	C	Si	Mn	P	S	Ni	Cr	Room Temp. Yield Point lbs./in.²	Room Temp. Tensile lbs./in.²	Static Test % Elong.	Static Test % Red. Area
	Percentage										
A7 carbon steel annealed	0.36	0.33	0.69	0.02	0.03	..	..	43,000	78,000	25½	60½
R6 carbon steel annealed	0.62	0.49	0.75	0.02	0.03	..	..	47,000	89,500	22½	51
Ni-Cr steel heat-treated	0.35	0.25	0.56	0.01	0.01	4.60	1.63	153,000	172,500	11	54
Lanz cast iron	3.19	1.09	0.82	0.12	0.13	..	..	.....	38,000	..	..

Endurance Limits

A7 (0.35% C)	20° C. 40,000; 325° C. 53,500; 550° C. 21,000±.
R6 (0.62% C)	20° C. 46,000; 310° C. 51,500; 425° C. 40,000; 550° C. 27,000; 710° C. less than 13,000.
Ni-Cr	20° C. 78,000; 100° C. 73,500; 200° C. less than 70,500; 300° C. 70,500; 400° C. 62,500±; 500° C. 46,000±.
Lanz cast iron	20° C. 14,000; 100° C. 13,000±; 200° C. 13,000±; 300° C. 15,500; 400° C. 16,500; 500° C. 14,000; 600° C. less than 10,000.

The cast iron specimens were taken from a hollow cylinder 27½ in. high, 25½ in. I.D., 1.6 in. wall thickness.

The endurance limits at 3000 R. P. M. are above the stresses at which the materials will fail through creep at high temperatures under static loading. Oxidation makes all endurance tests over 300° C. somewhat unreliable.

The same materials were tested after machining a round-bottomed notch of different depths in the breaking section. Room temperature endurance results on such notched bars follow:

	Notch Depth	Endurance Limit
A7	0.004	28,500
	0.012	22,500
R6	0.004	31,500
	0.008	27,500
	0.012	25,500
	0.200	23,000
Ni-Cr	0.002	51,000
	0.004	44,500
	0.008	39,000
	0.012	35,500
Lanz Iron	0.004	about 14,000
	0.200	about 14,000

As usual, the cast iron showed freedom from injury by the notches.

Steel R6 with 0.012-inch notch gave the following endurance limits at elevated temperatures: 150° C. 21,500; 330° C. 26,500; 425° C. 24,000; 550° C. 17,500.

The Ni-Cr steel with 0.004-inch notch gave: 100° C. 40,000; 200° C. 37,000; 300° C. 42,000; 400° C. 45,500; 500° C. 36,500

The fractures of the unnotched steel endurance specimens in the blue heat range were at 45°. At higher temperatures they were straight across the specimen, as were those of cast iron at all temperatures used. On all notched specimens at all temperatures the fractures were straight across.—H. W. Gillett (6)-B-

Working the Surface to Raise the Endurance Limit. (Das Oberflächendrücken zur Erhöhung der Drehschwingungsfestigkeit.) P. BEHRENS. *Veröffentlichungen des Wöhler-Institutes*, 1930, No. 6, 51 pages, 9 references 14 tables, 22 figures.

The damping limit of alloys is always increased by rolling the surface under pressure. The damping ability may be raised or lowered. The endurance limits of specimens of various materials were as follows: open hearth steel 6 to 29%; an 0.06% C structural steel, 21 to 50%; a 0.29% C, 1½% Mn, 9% Cr steel of 107,000 lbs./in.² tensile, 12 to 24%; a 0.33% C, 1% Cr, 0.18% Mo steel of 131,000 lbs./in.², 4 to 12%; brass with 2.3% Pb, 10 to 16%; brass with 1.4% Pb, 0 to 33%; brass with 56% Cu, 1% Mn, 7% Pb, balance Zn, 3½ to 13½%; electron 1% Zn, 6.3% Al, 0.3% Mn, 3 to 38%. The endurance limits were calculated on the basis of only 2 million cycles. HWG(6f)

Improvements on the Testing Machine for Tension-Compression Stress. (Verbesserungen an der Materialprüfmaschine für Zugdruckbeanspruchung. Vorspannung und Selbsterregung.) A. ESAU & E. VOIGT. *Zeitschrift für technische Physik*, Vol. 11, Feb. 1930, pages 55–58.

Paper pertains to a fatigue testing machine which was improved in the Techn. Phys. Institute of the University of Jena. EF(6f)

Taking of Samples and Testing of Material for Rotors. (Probeentnahme und Werkstoffprüfung an Rotorkörpern.) ERNST FRANKE. *Elektrotechnische Zeitschrift*, Vol. 52, May 7, 1931, pages 600–601.

The stresses to which a dynamo rotor is exposed are discussed and the danger of fracture due to fatigue is pointed out. The fatigue fracture is explained as follows: the stress caused by rotation gives rise to forces of motion within the structure which in time loosen up the crystal structure and, finally destroy it. Fine cracks are formed which become larger and wider until the stress for the remaining material becomes too great and a sudden fracture takes place. It is shown how and where samples of the forged piece should be taken and which requirements the testing machines for such samples have to fulfill. A brief description of such machines is given. Ha(6)

Fatigue Strength of Steel Joints Welded with Oxy-Acetylene. (Dauerfestigkeit der mittels Azetylen-Sauerstoff geschweissten Stahlverbindungen.) W. HOFFMANN. *Autogene Metallbearbeitung*, Vol. 24, Apr. 1, 1931, pages 99–102.

Reproduction of results of tests in tables and microphotographs, made on steel tubing, especially as used in airplane construction, for tensile strength, elongation, fatigue strength. With oxy-acetylene welding, an average of 90% of the normal values of the above mentioned properties can be attained. Fatigue tests gave 50 to 60% of the values of the normal material. Ha(6)

Machines for Fatigue Testing. (Maschinen für Dauerversuche.) W DEUTSCH. *Zeitschrift für Metallkunde*, Vol. 22, Feb. 1930, pages 56–61. See *Metals & Alloys*, Vol. 1, May 1930, page 524. (6)

The Effect of Surface Conditions and Electrodeposited Metals on the Resistance of Materials to Repeated Stresses. R. H. D. BARKLIE & H. J. DAVIS. *Proceedings Institution of Mechanical Engineers*, No. 3, May 1930, pages 731–750.

Studies Physical Qualities of Manganese and Alloy Steels. *Steel*, Vol. 87, Oct. 2, 1930, pages 71, 73.

Mn steel often attains a hardness of 550 Brinell under cold working in service. American Manganese Steel Co. has made numerous tests comparing the physical properties of work-hardened Mn steel with those of heat-treated alloy cast-steels. Some of these are presented graphically. These show that when the Fahrenwald abrasion factor was 150 for both, Mn steel had a tensile strength of 125,000 lbs./in.², surface hardness of 550 Brinell, elongation of 45%, and work factor of 3640 ft. lbs./in.³, while the corresponding values for the alloy steel were 220,000 lb./in.², 650, 0.70% and 58 ft. lbs./in.³ When compared on the basis of a tensile strength of 125,000 lbs./in.² for both, the alloy steel had a surface hardness of 275, elongation of 15%, abrasion factor of 110, and work factor of 1550 ft. lbs./in.³ On the basis of identical Brinell hardness of 550, the alloy steel had a tensile strength of 200,000 lbs./in.², abrasion factor of 120, elongation of 2%, and work factor of 242 ft. lbs./in.³ MS(6)

More on Endurance Testing with the M. A. N. Machine. (Weitere Erfahrungen in der Prüfung der Dauerfestigkeit verschiedener Werkstoffe auf der M. A. N. Biegeschwingungsmaschine.) A. JÜNGER. *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns*, Vol. 1, Feb. 1931, pages 45–58. 12 references.

The formula connecting endurance limit and the sum of the tensile strength, yield point and reduction of area is applied to some 20 more lots of steel, with fair concordance with experimental endurance data, but none of the steels were heat-treated to a very hard condition. A series of tests on specimens machined so that the planer tool marks were longitudinal or transverse, and of varying depths, as well as on polished, scratched and corroded surfaces, was run. Photographs of the surfaces are shown. The transversely planed specimens compared with those ground longitudinally showed a reduction in endurance limit ranging from 4% on the softest steel to between 40 and 50% for the harder steels. Specimens cut longitudinally and transversely from a crankshaft showed 10 to 25% lower endurance transversely. The static transverse data are not given so the applicability of the formula cannot be checked. Cylindrical specimens can be used instead of flat ones, the results agreeing fairly well. Using round specimens and spraying distilled water on them during the test for corrosion-fatigue, three steels showed 25 to 60% reduction in endurance limit. Similar spraying for 100 hours before the endurance test gave 10 to 30% reduction. The drop in endurance limit due to pre-corrosion was about the same as on specimens rough-planed transversely. The steel that was least affected by pre-corrosion was the most affected by simultaneous corrosion. One steel of .35% C, 88,000 lbs./in.² tensile, 52,000 lbs./in.² yield, 21.5% elongation, 55% reduction of area, 7 mkg./cm.² impact (Mesnager notch), was tested for endurance limit at elevated temperature. A heating coil was placed about the lower part of the specimen, just below the fillet, and a thermocouple inserted in a central hole extending through the lower part of the specimen nearly to the fillet. No calibration for temperature distribution is given and there is no certainty that the temperature at the breaking section may not have been considerably lower than that measured, especially at the higher temperatures. The endurance limits given are:

Temperature °C.	Temperature °F.	Endurance Limit lbs./in.²
Room		42,500
200	390	45,500
300	570	48,500
450	840	45,500
500	930	40,000

Electrodeposition of Silver from Sulfate, Nitrate, Fluoborate and Fluoride Solutions. EDWARD B. SANIGAR. *American Electrochemical Society, Preprint* 59–33, April 1931 meeting, 21 pages.

The possibility of electrodepositing Ag in a form suitable for electroplating purposes from silver sulphate, nitrate, fluoborate and fluoride solutions has been studied. Owing to the simple-immersion deposition of Ag from these solutions upon Cu, Ag, brass and Ni, adherent deposits were obtained only upon Ag. Relatively compact deposits of Ag were obtained upon Ag deposited from an argento-cyanide solution, from silver sulphate solutions containing boric acid, silver fluoborate solutions and silver fluoride solutions. However, these solutions showed a great tendency to yield tree deposits, and the conditions under which deposits free from trees could be obtained were limited. All the compact deposits were decidedly crystalline, and while they might be of use in the electro-refining of Ag as a means of obtaining dense Ag deposits instead of the loose crystals given by the nitrate solution, they offer no serious competition to the usual argento-cyanide solution for the electroplating of Ag, unless considerable improvement can be made, for example, by the use of "addition agents." A further difficulty in the way of the use of these baths for Ag deposition is the unsatisfactory corrosion of the anodes. (7a)

The Change in Reflecting Power Caused by Tarnishing Electrodeposited Silver-Cadmium Alloys. LAWRENCE E. STOUT & WILLIAM G. THUMMEL. *American Electrochemical Society, Preprint* 59–29, April 1931 meeting, 12 pages.

Silver-cadmium alloys may be deposited from a commercial cadmium plating bath to which silver cyanide has been added. The composition of the alloy depends on the silver concentration in the bath (if the cadmium content remains constant) and on the cathode current density. The co-deposition of silver lowers the reflecting power of electrodeposited cadmium. The tarnishing of the alloys depends both on the composition and on the rate of deposition, and is materially less than that of pure silver. A silver-cadmium alloy containing about 24% of silver recommends itself as the best general purpose reflector. Its reflecting power is equal to that of pure cadmium, and it is considerably harder and more resistant to abrasion than pure electrodeposited cadmium. (7a)

Chromium Deposits Directly on Aluminum. HAROLD K. WORK & CHARLES J. SLUNDER. *American Electrochemical Society, Preprint* 59–18, April 1931 meeting, 7 pages.

Thin layers of chromium which have fairly good resistance to salt spray and atmospheric corrosion may be electrodeposited directly on aluminum. Such deposits have a gray color on leaving the plating bath and must be buffed if a higher luster is required. These deposits protect aluminum to a marked degree from alkaline corrosion. Heavy deposits for abrasion resistance have also been applied to certain aluminum alloys. (7a)

Modern Methods of Nickel Plating. (Les methodes modernes de nickelage.) MARCEL BALLAY. *Revue Générale de l'Electricité*, Vol. 28, Aug. 2, 1930, pages 182–187.

From *Bulletin de la Société Française des Electriciens*, Series 4, Vol. 10, May 1930, pages 545–571. MS(7a)

Progress of the Hot Nickel Solution. OLIVER P. WATTS. *American Electrochemical Society, Preprint* 59–20, April 1931 meeting, 5 pages.

A report is made of the volume and operating conditions of many of the hot nickel plating solutions now in use in the United States and Canada. Since there was an incubation period of five years between the announcement of the advantages of heating the nickel plating solution and its commercial adoption, the reported growth to 158,000 gallons has occurred in ten years. Opinions of platers on the respective merits of the hot and cold nickel solutions are included. (7a)

The Hardness of Electrodeposits. D. J. MACNAUGHTON & A. W. HOTHERSALL. *Brass World*, Vol. 26, July 1930, pages 159–161.

High spots of the discussion following the reading of the paper are outlined. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 841. WHB(7a)

Bright Silver Plating from the Cyanide Bath. A Preliminary Note. L. C. PAN. *American Electrochemical Society, Preprint* 59–15, April 1931 meeting, 6 pages.

Ammonium hydroxide added to a silver plating bath has a whitening effect upon the silver deposit, especially when the bath contains an appreciable amount of impurities which otherwise cause discoloration of the cathode deposit. Sodium thiosulphate added to the extent of 1 g./l. makes the silver deposit almost of mirror brightness. The combination of ammonia and sodium thiosulphate gives a still more effective brightener for the silver deposits from a cyanide bath. (7a)

Control of Acidity in Low pH Nickel Plating Baths. L. C. PAN. *American Electrochemical Society, Preprint* 59–28, April 1931 meeting, 8 pages.

For the control of acidity in low pH nickel plating baths, the titration method, including a "control chart" for direct readings, was found to be most practical in a commercial plant. It is based upon the assumption that for a given bath whose composition is kept approximately constant, the pH value will be the same as long as the acidity is maintained at the same point. The "control chart" also provides a direct method of regulating and correcting the acidity or pH, eliminating all labor of computation and all guesswork. (7a)

Further Developments in Low pH Nickel Deposition. W. M. PHILLIPS. *American Electrochemical Society, Preprint* 59–35, April 1931 meeting, 4 pages.

Further commercial work with low pH nickel baths indicates the following: (1) Deposits from low pH baths furnish better protection than those from high pH baths. (2) The hardness of deposits is not directly influenced by the pH. Nickel is softer from baths operated at elevated temperatures. (3) Pitting is no worse with low pH than it is with high pH baths. See also *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. (7a)

Buffer Action in Nickel Plating Solutions. KARL PITSCHNER (Firestone Steel Products Co.). *Metal Industry*, N. Y., Vol. 29, Mar. 1931, pages 119–120; *Brass World*, Vol. 26, July 1930, page 175.

From the *Monthly Review of the American Electroplaters' Society*, Feb. 1931. Includes discussion. By noting the change in pH, when sulphuric acid is added to solutions with different contents of Ni, boric acid and ammonium chloride, it was found that the buffer effect is high at pH 6 and at pH 2 but low at pH 4. In the plating range pH 6 to 5, the buffer effect is more noticeable when alkali is added than when acid is added, while in the lower range the reverse is the case. Below pH 4, boric acid has little buffer effect in quantities up to 4 oz./gal.; at pH 5.5 the buffer effect of 4 oz./gal. is twice as much as if no boric acid is present and at pH 6 it is $3^1/_2$ times as great. Increasing the nickel sulphate concentration markedly increases the buffer effect if above pH 4. Increasing the ammonium chloride concentration increases the buffer effect considerably if above pH 4. PRK + WHB(7a)

The Electrodeposition of Chromium and the Influence of the Cathode Metal. J. W. CUTHBERTSON. *American Electrochemical Society, Preprint* 59–26, April 1931 meeting, 24 pages.

In chromium plating the best results and greatest flexibility and reliability in operation are obtained from a solution of chromic acid and sulphuric acid. The molarity of the CrO_3 should not be greater than 3.25, and the ratio of this to SO_4 normality should be about 58 to 60. The tank should be lined with hard lead, the lining not being anodic to the solution except as a temporary measure. Lead is the only material that can be considered for anodes. The temperature should be reasonably high, but not above 45° C., as then the Cr III equilibrium concentration reaches too high a figure. Care should be paid to the ratio between anode and cathode surfaces. The anode area should be 1.5 to 3 times that of the cathode, and anodes should be disposed with respect to the cathode size and shape. Even under the best of conditions, the cathode current efficiency is not above 16%. The nature of the cathode is of the greatest moment. It should be of a metal of high hydrogen overvoltage corresponding to that of chromium. Nickel is the material mostly used now, but is far from ideal. For many purposes copper is a far better undercoating. It is impossible to increase materially the throwing power of chromic acid solutions. The best way to improve upon existing conditions is to increase the plating range in which bright plate is obtainable. Except in the case of copper, little success has been obtained from chromium deposits direct on the base metal. This may be due to the inherent porosity of these deposits. Direct deposits can be improved by heat treatment, but this does not lend itself readily to commercial practice. (7a)

A Study of Silver Plating Solutions. B. EGEBERG & N. PROMISEL. *American Electrochemical Society, Preprint* 59–32, April 1931 meeting, 19 pages.

A discussion is given of the effects of temperature, current density and concentrations of silver, cyanide, carbonate and carbon disulphide on the resistivity, throwing power and cathodic and anodic polarization in argento-cyanide plating solutions. Curves are given to illustrate these effects. A comparison is made between solutions containing sodium salts and those containing potassium salts, and the advantages of the latter pointed out. Optimum plating conditions and compositions for above solutions are suggested. The subject is treated mainly from the industrial standpoint, although theory is also briefly considered where possible. (7a)

The Electrodeposition of Tungsten from Aqueous Solutions. COLIN G. FINK & FRANK L. JONES. *American Electrochemical Society, Preprint* 59–27, April 1931 meeting, 21 pages.

A method has been developed for the electrodeposition of metallic W from aqueous solutions. The W deposit is smooth, hard and coherent, having a high luster. Like Cr, the electrodeposited W needs no polishing if the plated article was previously polished. W has remarkable acid-resisting properties, which make it desirable as a protective coating for other metals. Several types of solutions have been investigated in regard to their usefulness as W plating baths. Solutions of W salts in organic solvents were found unsuitable for this purpose. Aqueous solutions of an acid nature did not give satisfactory metal deposits. Alkaline solutions containing alkaline tungstates were preferably used as plating baths. The temperature, cathode current density and hydrogen ion concentration of the solution must be controlled. Alloys of W and Fe, and of W and Ni, were electrodeposited from similar solutions containing very small concentrations of the ions of these second metals. The usefulness of highly alkaline solutions as plating baths for the electrodeposition of other metals is pointed out. (7a)

The Electrodeposition of Silver-Cadmium Alloys. COLIN G. FINK & BASIL G. GERAPOSTOLOU. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, pages 562–563.

Part 2. Conclusion of a paper presented before American Electroplaters' Society at Washington, July 2, 1930. Authors conclude that from experiments conducted following results were obtained: (1) Increase of metal ratio Cd/Ag in bath increases metal ratio Cd/Ag in the deposit; (2) increase in current density increases Cd % of deposit; (3) increase of temperature decreases Cd content of deposit and makes it brittle; (4) increase in free cyanide decreases cathode efficiency; (5) agitation hastens anode corrosion and decreases Cd content of deposits; (6) increase in Cd renders deposits hard and brittle; (7) microstructure shows heterogeneous mixture of at least two constituents; (8) low Cd deposit is not better than pure Ag for tarnish resistance. A Silver-White Alloy Plate. COLIN G. FINK & KIHOUGH H. LAH. *Monthly Review, American Electroplaters' Society*, Vol. 18, Jan. 1931, pages 29–34.

Includes discussion. See "The Deposition of Nickel-Cobalt Alloys," *Metals & Alloys*, Vol. 1, Dec. 1930, page 910. (7a)

Electrodeposition of Chromium-Iron Alloy. G. FUSEYA & K. SASAKI. *American Electrochemical Society, Preprint* 59–23, April 1931 meeting, 15 pages; *Journal Society of Chemical Industry*, Vol. 33, Nov. 1930, pages 474B–482B.

Experiments were performed to find the best conditions of electrodepositing chromium-iron alloys containing more than 16% chromium. A chromic acid bath for chromium plating, with iron salts added, did not give any good deposit of the alloy, and, therefore, sulphate baths containing from 52 to 130 g./l. Cr, 7 to 30 g./l. Fe and 0.05 to 0.1 molar in H_2SO_4 were electrolyzed between Cu cathodes and magnetite anodes. It was found that the longer the duration of electrolysis the lower the Cr content of the deposit. The higher the current density, and the lower the temperature or the acidity of the bath, the higher the Cr content of the deposit. A search of the literature indicated that no previous work had been done on the electrodeposition of this alloy. MB(7a)

The Limiting Current Density in the Electrodeposition of Noble Metals. S. GLASSTONE. *American Electrochemical Society, Preprint* 59–12, April 1931 meeting, 8 pages.

The literature of electrochemistry does not appear to contain a simple equation permitting the calculation of the maximum, or limiting, current density at which a metal can be deposited with 100% current efficiency. Such an equation is now developed on the assumption that the maximum rate of deposition is equal to the maximum rate at which the ions containing the metal to be deposited can diffuse up to the cathode. The values calculated in this manner are shown to be in good agreement with those observed, although discrepancies may arise when there is a possibility of hydrogen evolution. (7a)

Electroplating—Recent Developments and Future Prospects. COLIN G. FINK. *Iron Age*, Vol. 127, Jan. 1, 1931, pages 48–49.

The outstanding electroplating metal is Cr. Cr plating has been resorted to on 3 counts: (1) as protective coating guarding underlying metal against corrosion; (2) used for decorative purposes; (3) used for special purposes such as rubber molds and special bearings. Zn and Cd for plating will be superior to either metal alone. Several alloys can now be successfully electrodeposited, for instance, Fe-Ni, Cu-Ni, Au-Ni, Pb-Ag, etc. New electrolytic cleaning process developed by the Bullard Co. Research activities are greater at present than ever before. VSP(7a)

Chemicals—Their Functions in Electroplating. L. C. PAN. *Brass World*, Vol. 27, May 1931, pages 79–81.

The metal compound, the conductor, the anode depolarizer, the brightening agent, and the buffer—the parts they play in electroplating solutions are briefly discussed. WHB(7a)

Recent Electroplating Literature. A. K. GRAHAM. *Metal Industry*, New York, Vol. 28, Nov. 1930, pages 524–526; Dec. 1930, pages 558–561.

The Electrodeposition of Zinc on Aluminium from Sulphate Solutions. H. C. COCKS. *Transactions Faraday Society*, Vol. 26, Sept. 1930, pages 517–526.
Measurements have been made of the deposition potential of zinc in zinc sulphate solutions, with and without addition agents (1) with current density, (2) with pH of the solutions as the only variable. The use of buffered zinc sulphate solutions for the plating of aluminum on a commercial scale is suggested. Suitable electrolytes are:
N.$ZnSO_4$, 0.25 N. NaAc, 1 g./l. gum arabic, 0.1 g./l. *beta*-naphthol.
N.$ZnSO_4$, 0.25 N. NaAc, 1 g./l. gum arabic.
The paper is illustrated by two tables and one diagram embodying a number of curves. OWE(7a)

Electrodeposition of Platinum, Palladium and Rhodium. W. KEITEL & H. E. ZSCHIEGNER. *American Electrochemical Society, Preprint* 59–14, April 1931 meeting, 3 pages.
The chloride plating bath for Pt metals is not satisfactory due to its short life. A new bath was accordingly developed in which the Pt is present as the di-amminonitrite. Good, bright adherent deposits are obtained. The throwing power is very good. A similar bath for Pd was likewise developed and has given very satisfactory results. (7a)

Introduction of Iron into Alkaline Cleaning and Plating Solutions. E. J. LISCOMB. *Monthly Review, American Electroplaters' Society*, Vol. 18, Jan. 1931, pages 17–29.
Includes discussion. See "The Contamination of Solutions," *Metals & Alloys*, Vol. 2, Jan. 1931, page 8. (7a)

Mechanical Plater for Chromium. *Brass World*, Vol. 27, Apr. 1931, page 82.
At the Mansfield, O., plant of the Westinghouse Electric and Manufacturing Co. a conveyor type mechanical plating machine has been installed by Frederic B. Stevens, Inc., Detroit, Mich. The tanks are grouped in oval arrangement, a conveyor mechanism running above them supported on a structural steel support member. The manufacturers claim the machine to be universal and that any kind of plating or cleaning operations can be handled in it by rearrangement of sequences. The absence of overhead construction is an advantage. WHB(7a)

Electroplaters' and Depositors' Technical Society Annual Election and Round Table Discussion. *Metal Industry*, London, Vol. 37, Aug. 8, 1930, pages 129–130, 180, 182.
Meeting was devoted to the annual election of committee and officers, followed by round table discussion of methods of nickel plating P-bronze and Ni-Ag and other problems on electroplating. VSP(7a)

Electrodepositing Lead-Thallium Alloys. COLIN G. FINK & CLARENCE K. CONARD, JR. (Columbia University). *Metal Industry*, N. Y., Vol. 29, Mar. 1931, pages 116–117.
A good deposit of an alloy of 70% Pb and 30% Th was obtained on brass, using a perchlorate solution of 30 g./l. thallium, 5 g./l. lead, 20–30 g./l. free acid and a current density of 5 amps./ft.^{2} at 25° C. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. PRK(7a)

The Conductivity of Strong Electrolytes. RICHARD E. PAUL. *Chemical Engineering & Mining Review*, Vol. 23, Jan. 5, 1931, pages 157–160.
A summary of a lecture read before the Melbourne University Chemical Society, Oct. 22, 1930. Strong electrolytes do not show quantitative agreement with the theory of electrolytic dissociation. This is best explained most satisfactorily by the theory of inter-ionic attraction, which supplements rather than displaces the older dissociation theory. The fundamental idea of the inter-ionic attraction theory is that owing to the electrical attraction between the positive and negative ions, there are in the neighborhood of any ion, more ions of unlike sign than of like sign, and that when a solution is diluted, the separation of the ions involves doing internal work against this electrical attraction. Modification of the inter-ionic attraction theory of Debye and Huckel, by Onsager has made possible a complete explanation for changes in conductivity of very dilute solutions. The electrolytic conductivity is governed by two factors—the mobility change as predicted by Onsager's equation and the degree of dissociation which varies in agreement with the mass action law. At higher concentrations Onsager's equation does not remain valid and additional factors exert an influence. Among these are viscosity of the solution and the possibility of complex ion formation. For more concentrated solutions, an empirical extension of Onsager's equation is: $\lambda\eta_2 = \lambda_0 - (0.224\lambda_0 + 50.5)f(c)$, where λ represents the viscosity and $f(c)$ is a function of the concentration. While not extremely accurate, it permits an estimate of the effect of inter-ionic forces at moderate concentrations. WHB(7a)

Present Position of Chromium Plating. *Iron & Coal Trades Review*, Vol. 120, Feb. 7, 1930, page 238.
Abstract report of the discussion at the Electroplaters' and Depositors' Technical Society's meeting, London, Jan. 31, 1930. Rather brief discussion of some of the problems and practices of the industry, including relation of current density and luster, defects, adhesion of nickel, temperature control, effect of the thickness of the deposit and suggests the trial of cadmium as an undercoat. Buffering the Nickel Solution. OLIVER P. WATTS. *Monthly Review, American Electroplaters' Society*, Vol. 18, Mar. 1931, pages 4–11.
Practical hints. The author believes that of the various buffers so far tested the acetate seems more promising for the nickel solution under ordinary conditions of operation. The discussion of the paper brought out many and varied points. MFB(7a)

Gold Plating Solutions in Practice. (Mitteilungen aus der Praxis über Goldbäder.) HANS HORNAUER. *Deutsche Goldschmiede-Zeitung*, Vol. 34, Apr. 11, 1931, pages 156–157.
A discussion of methods used in gold plating. Either cold or hot solutions can be used. In plating such articles as cups care must be taken to obtain a good deposit on the inside. Either soluble or insoluble anodes can be used. The color of the deposit can be changed by changing the current density or by the addition of a metallic salt to the electrolyte. The compositions of several plating solutions are given. A high current density gives dark gold, and a low density light gold. Cu and its alloys can be directly plated, but other materials must first be Cu plated. Cu in the electrolyte produces a reddish tinge; Ag a greenish deposit; As a dark green tint; and Cu together with Ag a rose tint. $K_3Fe(CN)_6$ in a solution produces a rose colored gold. The Au can be recovered from electrolytes by Zn dust. JLG(7a)

Copper Plating of Aluminum for Contact Purposes. (Verkupferung von Aluminium für Kontaktzwecke.) H. GINSBERG. *Aluminium, Hauszeitschrift der V. A. W. Erftwerk*, Vol. 2, Apr. 1930, pages 24–27.
Tests have been made to determine the behavior of copper plated aluminum contacts for which a special method is described to obtain a good adhesion of the copper to the aluminum. For this purpose, an artificial oxide film is first deposited. Technological and electrical test results show the advantage of this copper plating method. In average cases, contact resistance was found to be 2 to 3 times greater than that of bare copper. The applied pressure was 4 kg./mm.^{2} and the overlapping 14 times the thickness of the bar. Another good result was obtained by first depositing zinc and then the copper on the zinc. The compositions of the electrolytes for pretreatment and plating are given. Ha(7a)

New Copper Refinery at Montreal. *Metal Industry*, London, Vol. 38, Apr. 3, 1931, page 360.
The first refined copper from the new plant of the Canadian Copper Refineries, Ltd., is expected to come on the market in April. The capacity of the plant is 75,000 tons per year. The concentrated slimes will be sent to the U. S. for final treatment. PRK(7b)

The Causes and Prevention of Cloudiness in Chromium Plating. L. R. GRIFFITHS. *Metal Industry*, London, Vol. 38, Mar. 13, 1931, page 298; discussion in Vol. 38, Mar. 27, 1931, page 335.
Experiments showed that the appearance of cloudy patches on chromium plated surfaces is due to uneven distribution of polishing grease over the nickel surface. The high current density areas of nickel plated work are coarse grained and retain more grease from polishing wheels than other areas. The remedy is to increase throwing power of nickel plating solution by lowering current density. The cloudiness which appears on re-chromium plating may be prevented by anodic etching of nickel plate in sulphuric acid and repolishing the nickel. PRK(7a)

Chromium Plating Methods in the Noble Metal Industry. (Verchromungsverfahren in der Edelmetallindustrie.) RALPH W. HARBISON. *Deutsche Goldschmiede-Zeitung*, Vol. 34, Aug. 1, 1931, page 325.

Investigation of Anodes for Production of Electrolytic Zinc, II. H. R. HANLEY, C. Y. CLAYTON & D. F. WALSH (Missouri School of Mines). *American Institute of Mining and Metallurgical Engineers, Preprint* 1931, 5 pages.
The effect of additions of Ca, Ag, Tl and Sn on the anode potential and stability of Pb anodes was studied. The addition of Tl plus Ag to the Pb-Ca anode increased the stability but neutralized the effect of Ca on the anode potential. JLG(7b)

Minimum Voltage to Reduce Aluminum Oxide. ALBERT BROADUS NEWMAN & GEORGE GRANGER BROWN. *Industrial & Engineering Chemistry*, Vol. 22, Sept. 1930, pages 995–1000.
The specific heat of alumina has been determined and the minimum theoretical voltage required to reduce alumina to molten aluminum and gaseous oxygen has been computed. Allowing for the lowering of this voltage in commercial practice through the use of carbon anode, the theoretical minimum voltage at 950° C. is computed to be 0.947. 16 references. MEH(7b)

The Separation of Ytterbium by Electrolytic Reduction. Observations on the Rare Earths. XXXVI. ROBERT W. BALL WITH L. F. YNTEMA. *Journal American Chemical Society*, Vol. 52, Nov. 1930, pages 4264–4268.
Bivalent ytterbium sulphate may be precipitated from an acid solution by electrolytic reduction in the presence of the sulphate ion. Arc spectrum analysis indicates that ytterbium of 98% purity may be separated in one operation from mixed ytterbium group material containing 2% ytterbium. Analysis of the precipitate showed it to be of variable composition approaching the formula $YbSO_4.xH_2O$. It is a very light green crystalline compound, soluble in dilute acids with the evolution of hydrogen and in nitric acid with evolution of oxides of nitrogen. The Yb ion is green. MEH(7b)

The Electrolytic Reduction of Acid Solutions of Molybdenum. (Ueber die elektrolytische Reduktion saurer Molybdänlösungen.) F. FOERSTER, F. FRICKE & R. HAUSWALD (Technische Hochschule, Dresden.) *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 146, Feb. 1930, pages 81–100, 177–231.
The electrolytic behavior of Mo^{IV}/Mo^{V} and of Mo^{V}/Mo^{III} solutions was studied and the reduction potentials at the cathode occurring during the electrolytic reduction process $Mo^{IV} \rightarrow Mo^{V}$ and $Mo^{V} \rightarrow Mo^{III}$ in HCl and H_2SO_4 solutions of various concentrations are compared. Especially for Pt and Au cathodes, the potential course proved to be materially different from a reversible one, which is only influenced by concentration polarization. The authors discovered the formation of diaphragms of changing properties at the cathode. Deductions from this observation are set forth, leading to new viewpoints concerning electrolytic reduction processes. EF(7b)

INDUSTRIAL USES & APPLICATIONS (9)

The Use of Zinc and Zinc Alloys in the Automotive Industry. ROBERT M. CURTS. *S. A. E. Journal*, Vol. 28, April 1931, pages 447–462; *American Metal Market*, Vol. 38, Jan. 30, 1931, page 13; Jan. 31, 1931, pages 5, 10; Feb. 3, 1931, pages 3, 5; Feb. 4, 1931, pages 5, 10; *Iron Age*, Vol. 127, Feb. 19, 1931, pages 622-626.

A brief review of the part that Zn and its alloys have played in the past and a discussion of recent developments in Zn-base alloys which have enhanced their field of use in the automotive industry. Features covered include: electro-zincing, rolled Zn and rolled-Zn alloys, Zn wire, extruded Zn shapes, die-castings, Zn alloys for body hardware and other equipment, Zn-Al alloys, heat treatment of Zn base alloys, physical properties of die-casting alloys, cleaning, etching and Ni plating processes for Zn die-castings. Cd plate may be applied directly with no appreciable harmful effects. Attractive coats of enamels, japans and lacquers may be applied to Zn and its alloys. Metallic Zn is used in the automotive industry for electro-galvanizing, as a constituent of brass, as rolled sheet and strip for a variety of fabricated products and in the production of a great number of die-cast parts. The physical properties of the various alloys and the ease of application of attractive and durable plated finishes have resulted in annual increases in the Zn consumption for automobile parts. Tables show the A. S. T. M. specification B 6–18-Spelter and the physical and electric properties of a Zn die-casting alloy containing 4% Al, 3% Cu, 0.5–1.0% Mg and the balance Horsehead special Zn. Brass, Bronze and Other Copper Alloys for Spring Making. *The Mainspring*, published by The Wallace Barnes Co., Jan. 1931, pages 4–6.

A non-technical discussion which, however, includes useful tables. MFB(9)

Casting for Bronze Gears. Part II. FRANCIS W. ROWE (David Brown & Sons). *Metallurgia*, Vol. 3, Feb. 1931, pages 144–146.

Only Sn and Sn-P bronzes have been found to be universally suitable for heavy duty gears. The bronze used in gears should have a low coefficient of friction, and a high resistance to wear. Discusses mechanical properties required of good bronze gears. JLG(9)

The Trend of Aluminum. *Metal Industry*, N. Y., Vol. 29, Apr. 1931, page 166.

The use for aluminum will grow mainly by its extension into the building industry, its use in electrical work and by the expansion of the transportation industry. PRK(9)

The Aluminum Contact. (Der Aluminiumkontakt.) HANS SCHMITT & B. WULFF. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Apr. 1930, pages 28–33.

A very exhaustive investigation into the electric resistance of metallic contacts with reference to pressure, surface area and nature of the surface. Copper and aluminum bars of 40 × 6 mm. were compared. It was found again that, for aluminum bars, the contact resistances at a certain pressure became greater, the more smoothly the surface was prepared, and that an application of a rough file just before the contact is made gave the best results. A slight coating with vaseline and the use of emery paper is good. For coppered aluminum contacts, the best results were obtained for copper deposited on a zinc plated bar. Ha(9)

Aluminum as a Roofing Material. E. S. WOODWARD. *Sheet Metal Worker*, Vol. 22, Feb. 6, 1931, pages 71–72.

General discussion on the application of aluminum as roofing material. GN(9)

Air Transformers with Aluminum Windings. (Lufttransformatoren mit Aluminiumwicklung.) UNGER. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, June 1930, pages 84–90.

An experimental transformer is described with windings of aluminum and aluminum oxide insulation and impregnated with kaolin enamel. The transformer could stand very high overloads. The heat radiation of the coil was held at 0.116 watts/cm.^{2} Ha(9)

The Use of Aluminum in Switching Installations. (Die Verwendung von Aluminium in Schaltanlagen.) SCHMITT. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Apr. 1930, pages 3–18.

Aluminum as material for bus bars and transmission lines has already found a very wide application. Several examples of European and American installations are illustrated. The respective advantages of aluminum over copper are discussed in detail with respect to mechanical stresses due to weight and short-circuits, heating by normal current, skin effect, heating by short-circuit currents and safety against arcing. Contacts between aluminum bars should be pressed together with about 2–3 kg./mm.^{2} and the current density not be more than about 0.1 amp./mm.^{2} Aluminum bars, pipes and wires can now be welded very satisfactorily. The best method is autogenous welding; as a flux, Autogal and Firinit are recommended. The economy to be realized by the use of aluminum of equivalent conductivity of copper is a saving of 47% in price, taking the cost of 222 RM/100 kg. Cu and 238 RM/100 kg. Al (in bars) at the time of the writing of the paper. The costs for installations are about the same; the behavior at short-circuit with respect to heating, better; and, for long transmission lines, great savings can be made in supporting towers. Ha(9)

Rolled Gold: Its Origin and Development. ERNEST A. SMITH. *Metal Industry*, London, Vol 37, Sept. 19, 1930, pages 275–276; Sept. 26, 1930, pages 299–301; *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 175–205.

Deals briefly with the history of the rolled-gold industry. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 912. VSP(9)

The Use of Nickel in the Electrical Industry and in Electrodeposition. (Die Anwendung des Nickels in der elektrischen Industrie und Galvanotechnik.) M. BALLAY. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, pages 204–205; *Revue du Nickel*, Vol. 2, Jan. 1931, pages 2–15.

Brief reference to the paper read at the International Congress of Mining, Metallurgy and Applied Geology, Liege, June 1930. EF(9)

Aluminum Tank Cars for the Chemical Industry. (Aluminium Kesselwagen für die chemische Industrie.) BUSCHLINGER. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Nov. 1930, pages 218–221.

For the transport of concentrated nitric acid, ammonia water, formaldehyde and liquid motor fuels, aluminum tank cars of sufficiently thick plates which are welded together permit the carrying of a greater useful load for the same total weight. In cases where formerly earthenware tanks were used on railroad cars and caused heavy damage by breaking, aluminum has been substituted to great advantage. Motor trucks and railroad cars are illustrated. Ha(9)

Aluminum and Aluminum Alloys as Materials in the Chemical Industry. (Aluminium und Aluminiumlegierungen als Baustoffe in der chemischen Industrie.) DR. DORNAUF. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Nov. 1930, pages 196–217.

Numerous illustrations of all kinds of apparatus used in chemical plants. Ha(9)

Light Metal Construction in Transportation. (Leichtmetallbau im Verkehrwesen.) FRITZ GENTZCKE. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Sept.-Oct. 1930, pages 135–157.

This paper deals fairly exhaustively, though in a general way, with the properties of high grade light metals and their possible economical application in industry and technique. Constructions and new ideas, especially, are discussed for the use of vehicles of all kinds; comparisons with other structural materials are made. Many diagrams and tables show the mechanical and physical properties of the most-used light metals. Methods of working, selection of construction elements, treatment of surfaces are described and critically compared. The economy is thoroughly treated and rentability calculations, especially for transportation, are made. Many illustrations show details of construction of motor coaches, buses and other vehicles and, also, of construction parts. Ha(9)

Experiments with Ladder Rungs of Wood and of Lautal. (Versuche mit Leitersprossen aus Holz und aus Lautal.) M. P. A. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Sept.-Oct. 1930, pages 157–158.

For the use of lautal as material for rungs of 5 ladders, tests showed superiority over rungs of ash wood. In a flame of 850–900° C. up to 40 sec., the wood became entirely useless, while the lautal rungs, made of hollow profile 12 × 25 × 0.75 mm., showed only slight bending with a sag of 1.2 mm. in a length of 250 mm. The weights were 57 g. for wood and 48 g. for lautal. Ha(9)

Hard-Facing Metals—Their Applications. R. L. LERCH. *Welding*, Vol. 1, July 1930, pages 613–615.

Materials of red hardness are now successfully used to build up worn parts. A long list of various uses is given. The welding on of such materials usually results in a great economy. Ha(9)

Comparison of Weights of 17ST and Steel Tubular Structural Members Used in Aircraft Construction. E. C. HARTMANN (Aluminum Company of Am. Research Labs.). *Technical Note* No. 378, National Advisory Committee for Aeronautics, May 1931. 17 pages, 5 figures.

If it is permissible to have a larger outside diameter in the 17ST (Duralumin) tube, a tubular structural member designed for a 92,000 yield point steel can be made of equal strength in 17ST at a weight saving of 10 to 40%. For long columns and beams designed for a given deflection, the 17ST is 39% lighter. If the steel has a yield point of 115,000, the 17ST loses some of its advantage for tension members and short columns, and if the outside diameter is fixed at that of the steel tube, the steel will be the lighter. Detailed calculations and plots are given upon which these conclusions are based. HWG(9)

The Use of Nickel in Automobile Engineering. J. B. HOBLYN. *Automobile Engineer*, Vol. 20, Sept. 1930, pages 339–340.

Summary of uses in various parts. Chassis, 3% Ni, C 0.15–0.20% increases strength without sacrifice of ductility. Shackle bolts, 3–5% nickel case hardening steel, C not over 0.15%. Front axle, 0.4% C, 1% Ni, water hardened. For highly strained axles, add ¾% Cr. Rear axle, 3% Ni-Cr steel, oil hardened. For heavier vehicles, 4.25% Ni, 1.25% Cr, 0.28% C, air hardened. Gears, 3–5% Ni or 3% Ni-Cr steel, case hardened, 1½–3½% Ni-Cr, oil hardened. Cylinders, 3.5% and up of Ni. Valves, 20% Ni-Cr steel. RHP(9)

Alloys of Aluminum and Magnesium in Modern Construction. (L'impiego delle leghe di alluminio e di magnesio nelle construzioni moderne.) G. GUZZONI (Instituto Scientifico Technico E. Breda, Milan). *La Metallurgia Italiana*, Vol. 23, Mar. 1931, pages 177–192.

The first of a series of articles on uses of light alloys. A list of common alloys (35 Al base and 20 Mg base) is given, with trade name or number, treatment, tensile strength and elongation and brief comment on characteristic mechanical properties. Comparisons of some of these with other materials of construction such as steel, alloy steel, cast iron, Cu, brass, bronze, wood, etc., in regard to weight, elastic limit, "limit of viscosity," elastic modulus, column strength and endurance limit are given, and the usual conclusions are reached as to fitness of the light alloys for engineering uses requiring maximum properties per unit weight. Brief comment is made on airplane longeron construction. HWG(9)

Skyscraper Employs 300 Tons of Corrosion-Resisting Steel. E. F. ROSS. *Steel*, Vol. 87, Aug. 7, 1930, pages 43–46, 50.

Empire State Building utilizes 300 tons of polished 18–8 Cr-Ni steel for window trim, ornamental sunbursts, store fronts and dirigible mooring mast. Describes fabricating operations at the plant of the United Metal Products Co., Canton, Ohio. These operations include a limited amount of punching on the corners of the sheets, bending or forming, spot and seam welding, polishing of the welded joints. Due to the great hardness of the 18–8 steel, a die steel containing 1.00–1.50% Ni and 0.65–0.85% Cr is used in the forming brakes. A total spring back allowance of 15 minutes is found necessary. After fabrication, the sections are pickled in 25% HNO_3 at 120–125° F. for 20 min. Special precautions in handling and shipping are taken. MS(9)

Pure Aluminum in Electrical Industry. (Rein-Aluminium in der Elektrotechnik.) A. SCHULZE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Nov. 29, 1930, pages 1653–1654.

A review of the studies of H. Schmitt on the special suitability of aluminum in switching and power plants in which the connections and bus bars must stand mechanical stresses due to their own weight and to short-circuits, and heating by the normal current. A further question is their skin effect and alternating current resistance, joints and contact resistance and weldability. The following table shows the most important characteristic properties of pure Al and Cu for use in electric installations:

	Al	Cu
Specific gravity	2.7	8.89
Electric conductivity, hard	35.2	57
Electric conductivity, soft	36	58
Specific resistance, hard	0.02845	0.0175
Specific resistance, soft	0.02780	0.0172
Temperature coefficient	0.00408	0.00393
Specific heat	0.214	0.0933
Heat conductivity, cal./cm./sec./degree	0.5	0.8–0.9
Melting point ° C.	658	1083
Fusion heat, kcal./kg.	100	43.3
Tensile strength, hard kg./mm.^{2}	18–25	30–35
Tensile strength, semi-hard kg./mm.^{2}	11–13	28–30
Modulus of Elasticity	630–750,000	1,300,000
Linear expansion coefficient	0.000027	0.00001698

The advantages of Al in certain cases are pointed out and tests have shown that for a given large short-circuit energy, Al is more economical. Joints are often coppered to reduce the contact resistance. Ha(9)

HEAT TREATMENT (10)

Effect of Heat Treatments on Efficiency of High-Speed Steels. ERDMANN KOTHNY. *Iron Age*, Vol. 126, Dec. 18, 1930, pages 1848–1852.

Translated from *Maschinenbau*. Describes tests carried out: (1) to test correctness of Oertel and Pölzguter's contention that effect of tempering on cutting efficiency diminishes as alloy percentage rises; (2) to determine influence of tempering when different hardening temperatures are used; (3) to prove influence of tempering when machining very hard and medium hard steel. Results show that cutting efficiency of high-speed steels, working on hard and medium steels, can be increased by tempering at 590° C. Investigations also cover the influence of tempering at 350° C. Contains numerous illustrations. Tabulates results of tests. VSP(10)

The Heat Treatment of Aluminum Alloys. ROBERT J. ANDERSON. *Metals & Alloys*, Sept. 1930, pages 721–726; Oct. 1930, pages 775–780.

A review. Bibliography of 55 references. ESC(10)

Heat Treatment of Aircraft Engine Parts. R. R. MOORE. *Fuels & Furnaces*, Vol. 9, Mar. 1931, pages 279–289.

Outlines importance of proper heat treatment and describes methods of heat treating steel and Al alloy parts. Tabulates chemical composition and physical properties of the Al alloys. See *Metals & Alloys*, Vol. 2, May 1931, page 103. MS(10)

Effects of Prequench Treatments on Hardened Tool Steel. R. H. HARRINGTON. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1363–1364.

Abstract of paper read before the American Society for Steel Treating. MS(10)

Heat Treatment of Delicate Tools of High Speed Steel. SAM TOUR (Lucius Pitkin, Inc.). *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1251–1256, 1258.

Study of the recommended practice of the American Society for Steel Treating for heat treatment of 18% W high-speed steel indicates that in the ordinary methods of heat treating to 2400° F., blistering, pitting, scaling, etc., results, and excessive grain growth is liable to develop. An electric furnace has recently been developed in which heating is by radiation and in which the atmosphere is practically stationary and made up of products of combustion of gas and air accurately controlled to give a true neutral atmosphere. Small intricate tools heated to 2350–2400° F. in the furnace showed no evidence of scaling, pitting, carburization or decarburization. It was not necessary to grind the surface after heat treatment. To test the question of excessive grain growth, samples 1 in. long and 1/2 in. diameter were prepared. Three were preheated at 1600° F. in an oxidizing atmosphere, transferred to the high heat of 2400° F., oxidizing atmosphere, and held for 1 1/4, 2 1/2 and 5 min., respectively. Four were preheated at 1600° F. in a neutral atmosphere, transferred to the high heat of 2400° F., neutral atmosphere, and held for 1 1/4, 2 1/2, 5 and 10 min., respectively. All were quenched in oil at 250° F. Microscopic examination showed that there was no appreciable grain growth in either atmosphere after 1 1/2 min. For the longer exposures, there was a greater amount of grain growth in the oxidizing atmosphere, this being decidedly so for the 5-min. sample. The one soaked for 10 min. in the neutral atmosphere did not show excessive grain growth. MS(10)

Hardening (10a)

The Mechanism of the Hardening of Steel. (Ueber den Mechanismus der Stahlhärtung.) G. KURDJUMOW & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 70–78.

On the quenching of carbon steel from the γ field, some face-centered cubic γ crystals remain, the rest changes to an instable tetragonal phase which differs little from the body centered cubic α crystals, but which can hold carbon in solid solution. In order to produce a large austenite crystal a 1.4% C steel was melted in an alumina crucible of 10 mm. diameter, 70 mm. long, the crucible chilled at one end to start freezing, the furnace temperature lowered to 1100° C., held for 1 1/2 hours and the steel then quenched in water. The specimen was piped, brittle and contained large crystals of martensitic structure, from which specimens were ground out and etched, for X-ray study. This showed relationships as follows:

Tetragonal Phase to Austenite		Alpha Iron to Austenite	
(011)	(111)	(011)	(111)
[1$\bar{1}$1]	[10$\bar{1}$]	[1$\bar{1}$1]	[10$\bar{1}$]
(001) 9° from	{100}	(001) 10.5° from	{100}
(100) 4.5° from	{110}	(100) 5.5° from	{110}
(010) 8° from	{110}	(010) 10° from	{110}

The change of the tetragonal to the α phase by simple gliding through the small angles and tiny distances required, and accompanied by a contraction of the lattice from 2.51 to 2.48 A. U. is shown by diagrams, and many X-ray photograms are reproduced. The transformation of the tetragonal phase to the α on heating at 100° was followed by the X-ray method. About 40% is transformed in 1/2 hour, 65% in an hour and 95% in 2 hours. The authors do not venture to decide, on the basis of their X-ray observations, whether the hardness of martensite is due to small crystal size or to internal stress. See also *Metals & Alloys*, Vol. 2, Mar. 1931, page 69. HWG(10a)

Hardening Crown Gears. *Automobile Engineer*, Vol. 20, Sept. 1930, pages 325–326.

Description of an apparatus designed by W. Ferd. Klingelnberg Söhne. The work rests upon a fixed support between dies which are hydraulically pressed together and a flood of oil cooled for hardening and having a uniform temperature is forced across all parts to be quenched with a constant velocity. Claim is made that this prevents distortion such as is apt to occur when the gear is quenched by dipping. RHP(10a)

Annealing (10b)

Continuous Annealing Process and the Principles of Heat Transmission. (Das Durchziehglühverfahren und die Grundlagen der Wärmeübertragung.) O. JUNKER. *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 124–125.

Stresses the annealing process of metal in strip form by continually pulling the material through the furnace. The theoretical possibilities of uniformly annealing the material over the whole length is discussed. After describing the furnaces, the author confines himself to the theoretical principles of heat transmission calculations and compares the practical results obtained with the theoretic derivations. EF(10b)

Case Hardening & Nitrogen Hardening (10c)

Localized Case Hardening Applied to Bearing. *Steel*, Vol. 87, Sept. 11, 1930, page 69.

Thompson Products, Inc., Cleveland, Ohio, carburizes the inner surface of split bearings for automobile steering mechanism by a selective method. After finish machining the bearings are Cu plated. The Cu is removed from the wearing surface, which is to be carburized, by a round cupping tool. The bearings are next carburized, then hardened in a salt bath at 1425° F. and quenched in brine. MS(10c)

On the Nitriding of Iron and Iron Alloys. I. (Ueber die Nitrierung von Eisen und Eisenlegierungen. I.) W. EILENDER & O. MEYER. *Archiv für Eisenhüttenwesen*, Vol. 4, Jan. 1931, pages 343–352; *Stahl und Eisen*, Vol. 51, Jan. 29, 1931, page 130.

Alloys of Fe with Al, Cr, Mo and V were nitrided at constant velocities of the stream of ammonia and constant temperatures. The surface hardness and the depth hardness as well as the structural changes were studied. The hardness was determined with the Rockwell machine as well as with Herbert's pendulum tester. In nitriding electrolytic iron between 200° and 1000° C., two different zones were observed below 600° C. Above 600° C., appears the eutectoid Braunit. The constant of diffusion of nitrogen was determined to be $k = 2.14 \times 10^{-8}$ cm./sec. at 550° C. The type and order of the diffusion of nitrogen seems to be similar to that of carbon. The chemistry of the process is discussed, with particular regard to the retarding influence of carbon on the nitriding process. In nitriding Fe-Al, Fe-Cr, Fe-V and Fe-Mo alloys, it was found that the surface hardness does not increase above a certain concentration of the alloying element. Aluminum alloys with 1% Al have the greatest hardness. Peculiar structures were observed in the Fe-Al alloys, resembling the rhythmic occurrences of precipitation in colloidal systems. The mechanism and chemistry in nitriding Fe-Al alloys is considered in detail. GN(10c)

Nitriding Symposium at National Metal Congress. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1381–1385.

Abstracts of papers presented at a symposium held by the American Society for Steel Treating, Sept. 22–26, 1930. MS(10c)

Carburization of Steel in a Gas Atmosphere. O. J. WILBOR & J. A. COMSTOCK. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1375–1376.

Abstract of a paper read before the American Society for Steel Treating. MS(10c)

Cementation of Aluminum. ROBERT J. ANDERSON. *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1243–1245.

Laboratory investigations of hardening the surface of Al by cementation have been successful, but no commercial process has yet been developed. Such metals as Fe, Cu, Cr, Co, Mn and Ni suggest themselves for this purpose. Chief difficulty is the formation of a film of Al_2O_3, which resists the penetration of alloying metals. Possible methods are the electrodeposition of a metal on the surface followed by heating at a temperature below the melting point of Al, and heating Al in contact with powdered metals, or gaseous or liquid metallic compounds. Most of the experimental work has been done on the first process and it is apparently the most successful to date. Cournot has done much work in this field. Possible applications of cemented Al are for corrosion-resisting purposes, e. g., in sea water and in alkaline liquors, and for articles where it would be desirable to increase the resistance of Al alloys to wear and abrasion, e. g., motor pistons. MS(10c)

Nitriding—Its Present and Future Status. V. O. HOMERBERG. *Iron Age*, Vol. 127, Jan. 1, 1931, page 52.

Outlines developments of nitriding. A new phase of nitriding is its application to surface hardening of special alloys tool steels. Nitromal, a malleable cast Fe which can be case-hardened with ammonia gas, can be made on a semi-commercial basis. Compositions of white cast Fe to give varying degrees of malleabilization have been evolved. Lists several investigations now under way at Nitralloy Corporation. VSP(10c)

Practical Suggestions on Nitriding. W. J. MERTEN (Westinghouse Elec. & Mfg. Co.). *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1235–1237.

To obtain desired uniformity, depth of case and hardness without brittleness, the structure of forgings and rolled bars is refined by heating at 1950–2000° F., soaking at a rate of 2 hrs./in. cross sectional diameter, and air cooling to a black heat. This is followed by reheating to 1550–1600° F., soaking at a rate of 1 hr./in. diameter and air cooling; then reheating to 1275° F. and furnace cooling to room temperature. Centerless-ground surface finish for cold-drawn bars is recommended for maximum hardness. Paste of SnO_2 made up with an alcoholic solution of shellac offers real protection to surfaces that are to be left soft. Charge should be so distributed in the container that there is a space of not less than 2 in. between the gas inlets and the charge. No charge should occupy the space 4 in. from the gas outlet. A maximum gas pressure of 1/4 in. Hg on a 2 in. deep Pb seal works well. Cooling the charge after processing in the closed box with NH_3 flowing, prevents discoloring and warping and results in a harder case. When testing hardness of case with the Vickers instrument care should be taken to see that the case is not pierced through. A minimum depth of 0.020 in. is required to avoid piercing through. Inlet piping must be made of Ni to avoid closing up of the perforation. Leaky joints are indicated by the formation of a white cloud of NH_4Cl when tested with a taper soaked in HCl. Case can be softened by immersing in an NH_4Cl-KCl bath at 1500° F. and allowing bath and part to cool to just above melting point of the salt mixture. Part is then taken from the bath while the salt is still liquid, the salt shaken from it and it is cooled slowly to room temperature. MS(10c)

Aging (10f)

Age-hardening of Austenite. F. R. HENSEL (Westinghouse Elec. & Mfg. Co.). *American Institute of Mining and Metallurgical Engineers, Technical Publication* No. 419, 1931, 25 pages.

Successful attempts were made to age-harden non-magnetic steels. Alloys were prepared by adding various amounts of Ti or Mo to a base alloy containing 15% Ni, 10% Mn and practically no C. The Ti alloys with a Ti content as high as 7% forged well. The Mo alloys contained as much as 15% Mo, and all forged well. Marked precipitation hardening was observed in alloys containing from 3 to 5% Ti, and in alloys containing over 13% Mo. The maximum hardness was produced by aging at 600° C. for the Ti alloys, and at 750° C. for the Mo alloys. The tensile strength of the Ti alloys increased on aging, but no increase was found in the Mo alloys even though their hardness increase was appreciable. An alloy of 12.67% Ni, 9.66% Mn, 3.96% Ti and 0.10% C had the following properties as quenched: Proportional limit 15,750 lb./in.^{2}, tensile strength 86,500 lb./in.^{2}, reduction of area 43.7%, elongation in 1 in. 36.5%, Brinell 174. After aging at 600° C. for 120 hr.: Proportional limit 25,000, tensile strength 125,500, reduction of area 8.5%, elongation in 1 in. 5.9%, Brinell 293. After aging at 550° C. the strength was slightly lower, 112,570 lb./in.^{2}, but the ductility was higher. Contains 16 references. JLG(10f)

The Artificial Ageing of Duralumin and Super-Duralumin. K. L. MEISSNER. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 207–240.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850 (10f)

Pressure-Aging of Duralumin. LEOPOLD PESSEL. *Industrial & Engineering Chemistry*, Vol. 22, July 1930, pages 776–777.

Tensile strength, elongation and hardness tests were conducted on duralumin before and after corrosion in a salt spray (20% NaCl) with samples that were aged under pressure and others aged without application of pressure. It has been shown that by the treatment given the duralumin, elongation increased appreciably in the aged specimen under pressure compared to those aged without pressure. The tensile strength and hardness showed a practically insignificant decrease. After exposure to corrosion, however, the decrease in tensile strength and elongation was much smaller in the duralumin that had been aged under pressure. The decrease in hardness due to corrosion was about the same with both methods. MEH(10f)

Sil-Fos

Brazing Alloy an Important Discovery

Stands 1490 Lbs. *Hydraulic Pressure*

One of America's leading refrigerator manufacturers has permitted us to photograph this evaporator unit used in testing SIL-FOS brazing alloy.

Its 29 joints, including the heavy forged brass head, were brazed with SIL-FOS in the ordinary way. Then *hydraulic* pressure was slowly applied and increased until the badly-distorted drawn brass shell finally burst, at *1490 lbs.* per sq. in.

***Not a drop of water issued from any one of the 29 joints* during the test, which lasted 10 minutes.**

Normal Unit, Before Test 29 Joints Brazed with Sil-Fos

SIL-FOS

FLOWS FREELY AT 1300° F. as compared with 1600° to 2100° F. for base metal brazing alloys.

Burst at 1490 lbs. Hydraulic Pressure Yet Not a Drop of Water Issued from Any Joint

PENETRATES QUICKLY and THOROUGHLY because of its silver content.

REQUIRES LESS FLUX ON MOST METALS because of the deoxidizing effect of phosphorus in the alloy. This means time saved in brazing, and less cleaning after the joint is finished. Under certain conditions satisfactory copper-to-copper joints can be made without using any flux.

WORKS FAST and is easy to use.

MAKES STRONG JOINTS which resist shock and vibration.

BRAZES COPPER and can be used in many cases for joining brass, bronze, nickel, nickel silver, extruded brass and bronze, monel metal and other metals and alloys fusing above 1300°F.

IS SURPRISINGLY LOW IN PRICE by the pound.

Although SIL-FOS contains silver, we offer it at prices ranging from $1.25 to $3.00 per *pound*, depending on size and quantity. Produced in the customary welding and brazing rod sizes, and in thin strip.

Send for Bulletin No. 59MA.

HANDY & HARMAN
57 William St., New York

JOINING OF METALS & ALLOYS (11)

Possibilities of Repair of Aluminum Pieces by Soldering and Welding. (Ausbesserungsmöglichkeiten von Aluminium-Werkstücken durch Löten und Schweissen.) H. Reininger. *Die Schmelzschweissung*, Vol. 10, Apr. 1931, pages 86–88.

Proper application of soldering and welding methods can often result in considerable saving of defective aluminum or aluminum alloy pieces. Suitable aluminum solders are described and welding methods discussed; the necessary mechanical and chemical pre-treatment described. A brief comparison of all important properties of the required rigid joints assists in selecting in every case the right method of repair. Possible errors are discussed and microphotographs show the structure of the joints made in different ways. Ha(11)

Brazing (11a)

Hard Soldering (Brazing) of Cast Iron. (Das Gusseisenhartlöten.) W. Anders. *Die Schmelzschweissung*, Vol. 10, Feb. 1931, pages 30–32.

A discussion of the metallographic and physical examination of cast iron soldered with Cu-Zn alloys shows that at the joints a zone of solid solution of Fe-Zn-Cu must be formed and C oxidized to CO_2 if a solid, reliable joint is to be obtained. Failures of brazing can always be traced to improper procedure and heat treatment. A properly soldered joint possesses greater strength than the cast iron piece. Ha(11a)

Electric Resistance Brazing Affords Durable Joints. G. E. Gifford (General Electric Co.). *Steel*, Vol. 87, Sept. 11, 1930, pages 59–60.

In resistance brazing, heat is generated by passing current through a pair of C blocks with the joint clamped between them. The C blocks heat readily and the heat is conducted into the pieces being brazed. Necessary equipment consists of a transformer, leads, foot switch, and tongs for holding the C blocks. Parts to be brazed are designed with flat surfaces or are flattened before they are clamped in the tongs. Alloys containing 10–50% Ag are generally used as the brazing medium. Alloy with 10% Ag melts at 830° C., that with 30% Ag, at 735° C., and the one with 50% Ag, at 725° C. Fused $Na_2B_4O_7$ generally is used as flux but in some cases it is more satisfactory to use KHF_2 in paste form. Glazing is less likely to occur if the flux is not put on until after the work has been clamped between the C blocks. Current is applied until the flux melts. A strip of Ag alloy then is held against the hot metal until the alloy flows between the pieces being brazed. Heat should be maintained until the flux appears as a thin fluid upon the surface of the molten alloy. The tongs are not to be removed or the pressure upon them released until the joint has cooled to a dull red color. The process takes much less time than soldering and makes a smaller joint which has better physical properties. MS(11a)

Soldering (11b)

Technique in Soldering "18–8" Steel Alloys. Robert T. MacGill. *Chemical & Metallurgical Engineering*, Vol. 38, Mar. 1931, page 169.

Practical hints. MFB(11b)

New Aluminum Solder. *Welding*, Vol. 2, Apr. 1931, page 241.

It is claimed that this new solder made by the Pittsburgh Metals Purifying Corp., Pittsburgh, Pa., makes joints stronger than the metal itself. No flux is used. Beside its use for duralumin, it is alleged that it is equally good for zinc and magnesium metals. Ha(11b)

Welding & Cutting (11c)

Facts Concerning Automatic Arc-Welding. A. M. Candy. *Welding*, Vol. 1, July 1930, pages 599–601.

Automatic welding requires a much more careful preparation of the pieces than the preparation for hand welding. The advantages, limitations and speeds obtainable are discussed and a few examples given. Ha(11c)

Selected Welded Constructions. (Ausgewählte Schweisskonstruktionen.) Vol. 2, Machine Construction. (Maschinenbau.) K. Haas. V. D. I. Verlag G. m. b. H., Berlin. 1930. Cloth, $8^1/_2 \times 11^1/_2$ inches, 97 pages. Price 14.50 RM.

The second volume of this ambitious publication fulfills the promise of the first volume (reviewed in *Metals & Alloys*, Vol. 2, Jan. 1931, page 34) and is, perhaps, more interesting as it shows to how great an extent modern welding practice has influenced machinery construction, to which the present volume is dedicated. The advantages of welded constructions over castings in this field are many; among them are especially savings in making patterns, in the foundry, shorter delivery and machining time—which can sometimes even be omitted entirely—and greater variety and freedom in shaping, as molding and casting need not be considered. A great many examples show the application in making jigs, templates and other devices required for machining. A most interesting example of combining constructive necessity with utility is the frame of a portable compressor, where the supporting frame is made up of tubes which, at the same time, serve as air tanks. Lathes, planers, etc., are made in this way just as cranes, hydraulic presses and blower-wheels. Of the 97 pages, 34 give examples of American practice which shows the author's impartiality in selecting good constructions. The whole book proves that welding does not simply replace riveted or cast elements of machinery, but that new ways have been found which utilize to the full the greater flexibility and economy which this process offers. Make-up and printing are excellent, as in the first volume.—M Hartenheim (11c)-B-

The Field of Welding. E. Gossow. *Engineering Progress*, Vol. 11, Oct. 1930, pages 261–267.

Based on various articles which have appeared in the *Zeitschrift Verein deutscher Ingenieure*. A review of some of the principal uses of welding are discussed by reference to examples of steel building, bridge work, traffic equipment and pipe line welding. RHP(11c)

Electric Welding of Steel. T. McLean Jasper. *Journal of the Western Society of Engineers*, Vol. 35, Dec. 1930, pages 415–422.

General discussion of arc welding of pressure vessels. GTM(11c)

The Cause and Prevention of Heat Cracks in Aircraft Welding. H. S. George (Union Carbide & Carbon Corp.). *Preprint* for May 1931 meeting Aeronautic Div., *American Society of Mechanical Engineers*, 7 pages.

Intercrystalline edge-cracking is often met in welding, and Cr Mo steel used in aircraft construction is especially susceptible because the stresses set up are intensified by its high strength and its air-hardening tendency. Welding toward the edge tends to prevent cracking, as is explained by a consideration of the localized stresses involved. Placing the weld in slight compression by clamping, and preheating are also helpful. Cracks may also be caused by internal stresses due to straightening, etc., but these stresses can be removed by a preliminary heating to a dull red to relieve them. 19 figures are included. HWG(11c)

The Training and Testing Institute for Welding of the Austrian Azetylen-Verein. (Die Schweisstechnische Lehr- und Versuchsanstalt des Oesterreichischen Azetylen-Vereins.) Adolf Fraenkel. *Mitteilungen des Staatlichen Technischen Versuchsamtes in Wien*, Vol. 19, 1930, pages 42–48.

A detailed description of buildings and equipment of the new institute. Ha(11c)

The Development of Welding Apparatus According to the Langmuir-Process in America and Germany. (Die Entwicklung der Schweissgeräte nach dem Langmuir-Verfahren in Amerika und Deutschland.) S. SANDELOWSKY. *Elektrotechnische Zeitschrift*, Vol. 51, Nov. 27, 1930, pages 1649–1652.

This method called the "Arcatom-method" is an electric arc welding process in which the arc burns within a protective atmosphere of hydrogen carried to 2 tungsten electrodes; the gas is disintegrated, in the arc, into 2H-atoms. The heat absorbed hereby from the arc is again liberated at the edge of the flame by combination of the 2H-atoms in molecules and pro-

duces a very high temperature of 3000–4000° C. which has the advantage of giving a high welding velocity and a low heating of the piece to be welded. The electrical apparatus used in this process and developed by the G. E. Co. and the A. E. G. are described, especially the burner and the transformer; the figure illustrates the welding capacities obtained under different conditions. Ha(11c)

Resistance Welding in American Automobile Manufacture. (Widerstandsschweissung im amerikanischen Automobilen.) H. DECHAMPS. *Automobiltechnische Zeitschrift*, Vol. 33, Jan. 10, 1931, pages 11–14; Jan. 31, 1931, pages 73–74.

The author points out the much greater use of welding in the manufacture of automobiles and some of the reasons why the German automobile industry is not so far advanced. A great number of special machinery and devices for welding parts are described and illustrated. Ha(11c)

Instruction in Welding. W. H. FLEW. *The Welder*, Vol. 2, Apr. 1931, pages 31–32.

Advocates proper training and careful selection of men. Ha(11c)

Aircraft Welding Requires Proper Tools and Methods. R. F. BISHOP. *Welding*, Vol. 2, May 1931, pages 313–315.

In welding a fuselage, 2 welders begin at the front and proceed toward the rear. The proper method is explained and some precautions to observe are pointed out. Ha(11c)

Six Miles of Automatic Welding. D. G. BAIRD. *Welding*, Vol. 1, July 1930, pages 606–608.

Carbon arc welding is widely used in shipbuilding. Examples of large-bulk cargo vessels and barges are given. The average welding speed was 60 ft./hr. Ha(11c)

Automatic Arc-Welding. F. L. BALLARD. *The Welder*, Vol. 2, Feb. 1931, pages 24–29.

The automatic arc-welder is a device for feeding the electrode from a drum to the work by means of a small constant speed motor driving a pair of knurled feed-rollers; the speed can be varied in the ratio 3:1. The current can be changed from 50 to 300 amp. The whole mechanical arrangement is described and set-ups for a few particular purposes are shown. The machine can be operated by semi-skilled labor. Ha(11c)

Training Arc-Welding Operators in the U. S. A. A. F. DAVIS. *The Welder*, Vol. 2, Apr. 1931, pages 26–30.

Requirements of teachers and students and the proper course of instruction are discussed. Ha(11c)

Manufacture of Welded Pipe by Means of Acetylene Welding. (Die Herstellung geschweisster Rohre mittels der Azetylen-Schweissung.) L. KAYSER. *Forschungsarbeiten auf dem Gebiete der Azetylen-Schweissung, herausgegeben vom Deutschen Azetylenverein*, Jan. 1930, pages 74–101.

In the particular field of welded pipes, research in the quality of the product, as independent of burner and gas quality, showed the same results as given in the paper of Mues in the same magazine. 16 references, many figures and photographs and tables supplement the paper, to which an appendix, treating of such pipes for structure and oxygen and carbon contents, is added. Ha(11c)

Recent Researches in Flame Cutting of Cast Iron. (Neuere Untersuchungen über das Brennschneiden von Gusseisen.) KALISCH. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 5, 1930, pages 61–65.

Cutting of cast iron by the oxygen burner has not given great satisfaction because of the imperfectness of the cutting. Recent tests made with oxygen and a small addition of acetylene gave better results when, at the same time, an additional material in the form of a welding rod was employed; this had the effect of burning the carbon in the iron. Ha(11c)

Modern Applications of Arc Welding. A. M. CANDY (Westinghouse Electric & Manufacturing Company). *Preprint, American Society for Testing Materials*, Mar. 1931, 21 pages.

Deals with necessity for design of structures to be built up by welding in such a manner as to utilize all possible advantages in weight saving rather than merely to duplicate the dimensions and looks of an object formerly made by casting or riveting. Illustrations are given in the field of electrical equipment, buildings and bridges. Advantages of automatic welding machines are stressed and devices for building up worn trolley wheel flanges and axle collars, for longitudinal tube seam welding and automobile rear axle housings, are illustrated. Much greater speed and uniformity of product are possible by automatic than by hand-welding, so when repetition work is concerned, and the cost of special automatic apparatus and of setting-up can be absorbed, it is much cheaper. HWG(11c)

Welding Equipment. (Schweissvorrichtungen.) NARATH. *Die Schmelzschweissung*, Vol. 9, Mar. 1930, pages 52–55.

Description of American and European auxiliary equipment for welding. Ha(11c)

Maintenance Welding in Steel Plants is Essential. E. L. QUINN. *Welding*, Vol. 2, May 1931, pages 320–325.

Welding as maintenance work is advocated; the maintenance department should coöperate with the metallurgical department. Ha(11c)

The Oxy-Acetylene Welding Process in Railway Shops. F. S. TINDER. *Welding*, Vol. 1, July 1930, pages 602–605.

Important points for satisfactory welds are: proper training of welders, supervision, correct preheating and annealing. These points are discussed in detail. Ha(11c)

Applications of the Welding Processes on the Boston & Maine. III. M. A. THOMPSON. *Welding*, Vol. 2, Jan. 1930, pages 168–170.

Cites some cost figures for gas-welding locomotive cylinders, frames and miscellaneous repair jobs. Ha(11c)

Procedure Control for Aircraft Welding. H. L. WHITTEMORE, JOHN J. CROWE & H. H. MOSS. *Welding*, Vol. 1, July 1930, pages 589–590.

The control should extend to apparatus used, such as torches, goggles, gases, hose, test of base metal for physical properties and weldability, welding rod inspection for similarity to material, qualifications. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 801. Ha(11c)

How Strong Are Welded Joints in Tubular Members of Airplanes? H. L. WHITTEMORE & W. C. BRUEGGEMAN. *Iron Age*, Vol. 126, Dec. 25, 1930, pages 1925–1926.

Taken from a paper read before the National Metal Congress. Gives results of a series of tests. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 914. VSP(11c)

Arc Welding Joints in Steel Structures. R. W. VAN KIRK (General Electric Co.). *American Metal Market*, Vol. 38, Mar. 12, 1931, page 10.

A paper presented at the Welding Conference, Georgia School of Technology, Atlanta, Ga. Electric welding has developed rapidly since 1915. Specifications regarding unit stresses are discussed, also the electric welded buildings of the Dallas Power & Light Co. and Dallas Gas Co. Five advantages of electric welding are: (1) reduction of noise during erection, (2) considerable saving in weight of steel, (3) electrically welded connections can be made stronger than the strongest possible riveted connections for the same purpose, (4) welded connections are more compact and require less material than riveted ones and (5) welded joints will not work loose. Qualifications of welding operators and shop and erection practice are touched upon. WHB(11c)

High Pressure Power Station Piping Welded with Stock Fittings. JOHN H. ZINK. *Welding*, Vol. 1, Apr. 1930, pages 385–389.

Describes the installation in the Bureau of Standards of 2 boilers of 500 and 360 h. p., respectively, at 200 lbs. water pressure and 100° superheating. Cost of welded fittings are compared with screw fittings and saving in weight, cost and labor are described. Ha(11c)

Advances in Welding and Cutting Cast Iron and Cast Steel. (Fortschritte im Schweissen und Schneiden von Gusseisen und Stahlguss.) H. WITTE. *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns*, Vol. 1, Feb. 1931, pages 58–61. 5 references.

General comment. Cutting of cast iron is accomplished by feeding into the cutting torch through a special nozzle, pulverized ferrosilicon, ferromanganese or aluminum, plus a flux such as borax, and maintaining the proper angle between the flame and the piece being cut. HWG(11c)

Lead "Burning" or Welding. FRANCIS A. WESTBROOK. *Metal Industry*, N. Y., Vol. 29, Apr. 1931, pages 152–154; *Metal Industry*, London, Vol. 38, May 8, 1931, pages 477-479.

A description of lead burning practice. PRK(11c)

Manufacture of Steel Elbows with Cutting and Welding Torch. (Stahlrohrkrümmerherstellung mit Schneid- und Schweissbrenner.) WECKWERTH & AMLING. *Die Schmelzschweissung*, Vol. 10, Apr. 1931, page 91.

A method is described and a table given for producing curved joints by cutting out triangular pieces from a cylindrical pipe, bending and welding the faces together, for use under any condition where standard fittings cannot be used. Ha(11c)

Small Crane Type Plate Shop All Welded. C. G. WATSON. *Welding*, Vol. 1, Apr. 1930, pages 390–391.

Describes the erection of a building with welded roof construction. Ha(11c)

Design and Uses of Arc-Welded Joints. NAT. WARSHAW. *Welding*, Vol. 1, July 1930, pages 591–595.

Thirty different joints are illustrated and their use recommended in the construction of machinery which can be made more economically in this way. Ha(11c)

Comparative Tests of Rivet and Plug Welds. THOS. K. VINCENT. *Welding*, Vol. 2, May 1931, pages 316–319.

Tests undertaken to determine whether it is economical to punch holes in one of 2 plates and then fasten the plates by plugging the holes with weld metal, fusing the plugs into the unpunched plate. No marked improvement could be noted from the tests and so the question remains open. Ha(11c)

Welded Pressure Vessels in England. *Welding*, Vol. 1, Apr. 1930, pages 378–383.

A tabulation of different methods of joining plates with coefficient of strength in percent of the solid metal is given and the factors necessary to secure a good weld are discussed. Ha(11c)

Successful Welds with Galvanized Iron. *Welding*, Vol. 1, Apr. 1930, pages 375–376.

Where the galvanized coating is destroyed by welding, welds are made either with a steel welding rod and later given a coat of paint, or with a bronze welding rod which needs no coating. The latter method has lately found fairly wide application for water lines of galvanized pipes. Ha(11c)

Railroad Welding Practice in Europe. *Welding*, Vol. 1, Apr. 1930, pages 371–374.

Shows illustrations of car underframes welded in Belgium. Ha(11c)

Welded Reinforcement for Water Pipe. *Welding*, Vol. 1, Jan. 1930, pages 181–184.

The method of laying of 2627 sections of 27 in. pipe 12 ft. long is described in detail. Ha(11c)

The Atomic Hydrogen Welding Process. *The Welder*, Vol. 2, Feb. 1931, pages 30–36.

The principle of this process consists of feeding hydrogen gas to 2 tungsten electrodes set at an angle of about 30°; a set of nozzles sends a stream of hydrogen to the points of the electrodes, thus performing the welding process in an atmosphere of hydrogen. Diagrams of electrical connections, mechanical arrangements and microphotographs are given. An average of 40 ft.³/hr. of gas is used. Ha(11c)

The Fabrication and Welding of H. R. Crown T Steel in Czecho-Slovakia. *The Welder*, Vol. 2, Feb. 1931, pages 16–19.

Brief description with photographs of 4 tanks 1000 mm. in diameter, 1200 mm. deep and 3.5 mm. thick of 18/8/1 chromium-nickel-tungsten steel. Ha(11c)

Pipe Welding, How, When and Where to Do It. WM. SPRARAGEN *Welding*, Vol. 2, May 1931, pages 303–307; June 1931, pages 389–393.
A general discussion of joining pipes for long pipe lines; butt joints, bell joints, sleeve reinforced joints are described. Ha(11c)

Welding High Manganese Steels, a Discussion of the Physical Properties, Weld Preparation and Procedure. *Welding News*, Vol. 2, Jan. 1931, pages 1–3.
Costly replacements of high manganese steel pieces can often be delayed by building up the worn parts, but the process must retain the high resistance against abrasion in the built-up part. It is recommended that the deposits be laid on in a series of pads instead of beads; the pads should be about 1 in. wide and $1^1/_4$ in. long. Before it cools to a dull red, the pad should be peened and hammered until almost cold. After cooling with water, the remaining strains should be taken out by hammering again. Instructions for the preparation of the work are also given. Ha(11c)

Directions for the Welding of Steel Structures. (Richtlinien für die Ausführung von Stahlbauten.) *Die Schmelzschweissung*, Vol. 9, Mar. 1930, pages 50–51.
This is a draft for general rules to be observed in welding structures, intended as an appendix to German official regulations and dealing with calculation and numerical values of stresses, guaranty tests of welds, erection instructions. Ha(11c)

Tests on Spot Welder. R. J. WILSON & P. L. ORR. *Welding*, Vol. 2 Apr. 1931, pages 238–241; May 1931, pages 300–302.
The article deals with the best ratio between spot diameter and plate thickness when using an electrode pressure of 14,000 lbs./in.^{2} throughout. A work sheet for different conditions is given. The tests were conducted with regard to pressure/unit square of electrode area to be applied, heat required for different thickness as well as the above-mentioned ratio. The results are given in tables and curves. Ha(11c)

The Training of Welders. D. RICHARDSON. *The Welder*, Vol. 2, Apr. 1931, pages 23–25.
A survey of different training methods in America and the Continent. Ha(11c)

The Welding of a Turbine Cylinder. P. L. ROBERTS. *The Welder*, Vol. 2, Feb. 1931, pages 11–15.
The iron casting for a turbine cylinder was found, after considerable machining had been done, to be defective; a great blow-hole and sand spot was found in the head. The correction of this defect by arc-welding is described in detail. After 2 years, the turbine is still running satisfactorily. Ha(11c)

Welded Steel Structures. Part II. EDWARD DACRE LACY. *Metallurgia*, Vol. 3, Feb. 1931, pages 151–152.
Welding construction is increasing in spite of many handicaps. JLG(11c)

Atomic Hydrogen Arc-Welding Process. *Electrical World*, Vol. 97, May 2, 1931, page 836.
A complete atomic-hydrogen arc-welding process has been developed in England. An alternating current is maintained between adjustable tungsten wire electrodes and hydrogen gas is fed to the arc around the electrodes. Hydrogen molecules are broken into atoms and, in recombining outside of the arc, heat is liberated far in excess of that obtained by a gas flame alone. This heat is used to fuse the metals to be joined. A transformer furnishes the required voltage and the current at the arc is regulated by a controlling reactor. High voltage and low currents are required in the arc. The arc is struck at 300 volts, but while welding the arc voltage is varied from 90 for light work to 60 for heavier, and the current correspondingly varies from 15–70 amps. WHB(11c)

Elementary Training in Welding. J. N. LONG. *The Welder*, Vol. 2, Apr. 1931, pages 19–22.
Outline of the course of the (British) Institution of Welding Engineers. Ha(11c)

Gas Engine Pistons Repaired by Welding. ORVILLE ADAMS. *The Welder*, Vol. 2, Apr. 1931, pages 13–15.
Description and illustrations of 29.5-in. pistons of 2000 h.p. tandem engine. Ha(11c)

Automatic Arc Welding. G. H. KOCH. *Electrical Engineering*, Vol. 50, May 1931, pages 358–360.
The use of arc welding has effected marked savings in the manufacture of electric apparatus. Automatic control has promoted still greater savings and better and more uniform products. Some savings in welding time are illustrated. WHB(11c)

The Strength and Design of Fusion Welds for Unfired Pressure Vessels. L. W. SCHUSTER. *Proceedings Institution of Mechanical Engineers*, No. 2, Mar. 1930, pages 319–417.
Includes discussion and appendix which presents tentative rules for fusion welding of unfired pressure vessels. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 801. RHP(11c)

An Advanced School for Welding Technique in France. (Eine höhere Fachschule für Schweisstechnik in Frankreich.) *Die Schmelzschweissung*, Vol. 10, Feb. 1931, page 29.
Practical and theoretical education for welders in 8 months. The whole course is outlined. Ha(11c)

The Use of a Cleansing Flux on the Reverse Side of the Weld. *Welding News*, Vol. 2, Jan. 1931, page 6.
Fluxes are used to eliminate and clean the oxides formed during the welding process. They are usually applied in the form of the filling rod. It was found that the application of the flux on both sides of the weld is of great advantage, especially with some metals that are more difficult to weld, such as aluminum. A few hints are given on the successful performance of this method. Ha(11c)

Autogenous Welding in French Boiler Construction. (Die autogene Schweissung im französischen Dampfkesselbau.) *L' Usine*, Vol. 39, April 25, 1930, page 47; *Die Schmelzschweissung*, Vol. 10, Feb. 1931, page 35.
The French ministry for public works has published regulations for autogenous welding for the construction and repair of boilers which give explicit instructions on how and when and with what precautions this method is permitted. Burner and consumption of acetylene and dimensions of electrodes are to be of approved construction. Ha(11c)

New Cross-field Welding Generator QV121. (Neuer Querfeld-Schweissgenerator QV121.) *AEG-Mitteilungen*, Vol. 4, Feb. 1931, page 81–83.
Description of the new DC-welding generator of the AEG for constant current, maximum 250 amp. which can be adjusted to any current desired by field regulators. Over-all efficiency of the welding plant 55 to 60%. Ha(11c)

Weapons of War Fabricated by Welding. J. B. ROSE. *Welding*, Vol. 2, Apr. 1931, pages 258–261.
The same factors that are causing many manufacturers of metal parts to turn to welding as a fabricating tool are responsible for the Ordnance Department of the U. S. A. to adopt welding as a process for assembling large and small guns. These factors eliminate castings to save weight and spoilage, to obtain a more rigid and dependable product, to improve on design, to reduce costs and speed up production . Some examples are illustrated. Ha(11c)

A Study of Gas Welds Made with Various Rods. *Welding*, Vol. 2, Jan. 1931, pages 34–36.
Describes a series of tests with oxy-acetylene welding to determine physical and microscopic properties of steel, cast iron and brass welds with several welding rods. All joints were simple, horizontally welded butt joints. Tables and micrographs illustrate the results which emphasize the importance of a skilled welder. Ha(11c)

Repairing Gears by Gas Welding. *Welding*, Vol. 2, Jan. 1931, page 24.
A few points on how best to proceed. Ha(11c)

Welding in Manganese Steel Plant. JOS. A. COYLE. *Welding*, Vol. 2, Feb. 1931, pages 97–98.
Oxy-acetylene cutting and electric welding is used by the American Manganese Steel Co. in Denver for their products of manganese steels used in railroad switches, airplanes, etc. The cost of production is reduced thereby. Ha(11c)

A 40,000-Lb. Steam Hammer Repaired by Welding. W. TH. P. MAEDER. *Welding*, Vol. 2, Jan. 1931, pages 20–21.
The piston rod of this hammer snapped and the base was broken. It was repaired by arc-welding in 10 days instead of the 30 days required if the pieces had been sent to the manufacturer. Ha(11c)

Use More Welded Structural Steel in United States. FRANK P. MCKIBBEN (General Electric Co.). *Steel*, Vol. 87, Aug. 7, 1930, pages 48, 50.
From paper presented at World Power Conference, Berlin, June 1930. Complete article appeared in *General Electric Review*, Vol. 33, Aug. 1930, 453-455. MS(11c)

Welding of Structural Steel Requires Understanding. FRANK P. MCKIBBEN. *Steel*, Vol. 87, Sept. 18, 1930, pages 60, 62.
Consists of 35 questions with brief answers. MS(11c)

All-Welded Automobile Shelter. J. F. MINNOTTE. *Welding*, Vol. 2, Jan. 1931, pages 37–39.
Replaces a wooden building; details of construction. Ha(11c)

Welded Radiators for Warm Water Heating. (Geschweisste Heizkörper für Warmwasserheizung.) M. MENGERINGHAUSEN. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 71–74.
Ornamental designs in various metals with regard to good radiation, easy accessibility for inspection and repair and possibility of extensions. Ha(11c)

Welding Cast Iron with Metallic Arc. M. C. MCOSCAR. *Welding*, Vol. 2, Jan. 1931, pages 31–33.
For successful welding of cast iron, the following 5 points are impressed: (1) The long arc produces a shallow crater preventing absorption of excessive carbon. The alternately long and short arc should be extensively practiced. (2) Sodium hydroxide with some binder, as slaked lime, should be used for welding iron not fusing readily. (3) Phosphor-copper or cupro-nickel alloy produces a machinable weld in cast iron, but should be used only on surfaces to be machined; all other welding should be done with a soft iron filler metal. (4) Peening where possible relieves contraction strains. (5) The weld or casting should never be permitted to become overheated while welding. This is extremely important. Ha(11c)

Rules for Welded Construction of Heating Installations. (Schweisstechnische Konstruktionsregeln bei der Herstellung von Heizungsanlagen.) W. JOHAG. *Schmelzschweissung*, Vol. 10, Mar. 1931, pages 53–54.
Welded constructions adapt themselves readily to local conditions; a few hints are given for the selection of parts and shapes to fit into a certain condition. Ha(11c)

Welded Joints in the Construction of Air Heaters. (Die Anwendung der Schweissverbindung beim Bau von Lufterhitzern.) R. BRASS. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 75–76.
Some constructions of pipe lines, ducts and heaters. Ha(11c)

Mechanical Difficulties Overcome in Welding Spiral Pipe. LEON CAMMEN. *Machine Design*, Vol. 3, May 1931, pages 43–45.
Describes several arrangements for rotating a cylindrical body by friction and at the same time moving the body forward, with special reference to the kind used in welding spiral pipe. A rope drive is a most effective type. Ha(11c)

Influence of Coatings of Welding Rods on the Strength of the Weld. (Einfluss von Umwicklungen der Schweisstäbe auf die Festigkeit der Schweisse.) K. BAUMGAERTEL. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Jan. 10, 1931, pages 53–54.
See *Metals & Alloys*, Vol. 2, Mar. 1931, page 70. Ha(11c)

What Has Been and Will Be Accomplished in the Field of Structural Arc-Welding. A. F. DAVIS. *Welding*, Vol. 2, Apr. 1931, pages 246–251.
The author reviews the methods applied in welding large structures, such as buildings, and investigates how much of it should be done in the shop and how much left to field-welding. He illustrates his point with a few examples. He recommends a certain standardization of parts and methods, and discusses inspection and tests to guarantee safety. A big asset of the welding method is the elimination of noise and possible economies in weight and speed of erection. Ha(11c)

Producing Electric Welded Pipe. A. H. ALLEN. *Steel*, Vol. 87, Aug. 14, 1930, pages 43–46.
Describes plant and practice of the Republic Steel Corp., Youngstown, Ohio. One unit forms and butt-welds 8-in. pipe in 40-ft. lengths at a speed of 40–60 ft./min. The process used is an amplification of the Johnson process for electric welding. It is a resistance welding process in which alternating current at high amperage is employed, no external weld metal being necessary. Each length is subjected to hydrostatic and hammering tests. It is claimed that the weld is stronger than the adjacent metal and has a sound microscopic structure. MS(11c)

Electric Railway Builds Welded Frogs. C. ANDERSON. *Welding*, Vol. 2, Feb. 1931, pages 93–94.
The Havana Electric Railway has constructed arc-welded frogs of steel rails and steel plates, cut to size and shape so as to fit into one another. It is claimed they are stronger, require less attention and maintenance work and are less likely to break. Ha(11c)

Design and Construction of Wrought Iron Water Tanks for Heating Purposes. (Bauart und Herstellung schmiedeeiserner Wasserbehälter für Heizzwecke.) ALFRED NAUCK. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 67–70.
Construction data for boilers with dimension tables for different capacities, for registers, heating spirals, etc., by welding. Ha(11c)

Welding Practice at San Francisco Plant of Link-Belt Company. G. P. NEWTON. *Welding*, Vol. 2, Mar. 1931, pages 188–190.
Welding has simplified design and layout work and produced conveyor equipment stronger than riveted construction. Ha(11c)

Fatigue Properties of Welds. J. B. JOHNSON. *Welding*, Vol. 2, Mar. 1931, pages 159–163.
Describes some fatigue test with results, from which it is concluded that the removal of the bead has little effect on a butt-welded seam on large parts but a considerable effect on small pieces about $^3/_4$ in. in diameter. Heat treatment such as annealing or normalizing will raise the fatigue limit. Improvement in welding technique which reduces the number and size of the oxide particles and blow-holes will also raise the fatigue limit. Six bibliographic references. Ha(11c)

Welding of Copper-Nickel Alloys. (Die Schweissung von Kupfer-Nickel-Legierungen.) HANS A. HORN. *Autogene Metallbearbeitung*, Vol. 24, Apr. 15, 1931, pages 119–122.

Exhaustive tests made with water-cooled pipes of Cu-Ni alloy were made to determine their behavior in sea water, when used as exhaust pipes in Diesel engines in ships. The alloys tested were 70% Cu with 30% Ni and 80% Cu with 20% Ni. It was found that these alloys can be welded even better than copper as the alloy is very liquid and clean welding seams can be made. Acetylene is well suited for welding these, but not hydrogen and illuminating gas. The acetylene must be absolutely free of hydrogen sulphide since, otherwise, brittle sulphur-nickel is formed. When welding sheets, it must be done very quickly and without interruption. Re-welding of welded seams is to be avoided. The welding rod must be of the same composition as the alloy and the thickness of the wire should be about the same as that of the piece to be welded. Ha(11c)

Items Affecting Welding Costs. W. L. FRANKLIN. *Welding*, Vol. 2, Apr. 1931, pages 232–234.

A brief analysis of those items which constitute welding costs. The influence of properly laying out the welding shop and the work to be done is discussed and a chart suggested for showing the cost relations. Ha(11c)

Gas Welding in Ventilation and Dust Exhaustion Installations. (Die Gasschmelzschweissung bei Entlüftungs- und Entstaubungsanlagen.) KARL FUNK. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 78–79.

Description of entirely welded ducts, joints and collecting tanks. Ha(11c)

Welding of Copper in Building of Apparatus. (Das Schweissen von Kupfer im Apparatebau.) GEIGER. *Die Schmelzschweissung*, Vol. 10, Feb. 1931, pages 37–38.

Riveting of copper vessels which are subject to temperature changes is unsatisfactory as the rivets soon become loose. Welding must be done by oxy-acetylene as experience has shown that electrically welded joints are not sufficiently corrosion-proof nor possess sufficient toughness and density. Due to the high thermal conductivity of copper, larger burners must be used than for iron. After welding, the seam must be strongly hammered and heated to about 500° to 550° C., then quickly cooled by compressed air or water. Instructions for making satisfactory welds are added and a few examples are described. Ha(11c)

Autogenously Welded Pipe Structures and their Flow-Resistance. (Autogengeschweisste Rohrformstücke und ihr Stromungswiderstand.) W. GELDBACH. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 64–66.

By properly shaped joints, knees, etc., the losses due to flow-resistance can be appreciably reduced. A table gives the loss coefficients for different elbows and flow velocities. Instructions for making branches are added. Ha(11c)

New Application Possibilities of Autogenous Welding in Ornamental Iron Work. (Neue Anwendungsmöglichkeiten der autogenen Schweissung bei Eisenarbeiten.) J. BLUEMMEL. *Die Schmelzschweissung*, Vol. 10, Feb. 1931, pages 27–28.

In a few examples, it is shown how the crater forming in welding might lend itself as a characteristic element in producing artistic effects in welded ornamental iron work. Ha(11c)

Welded Structures in Germany and Austria. OTTO BONDY. *Welding*, Vol. 2, Feb. 1931, pages 110–113.

The new rules governing the erection of welded steel buildings as issued by the Prussian Ministry of Public Safety are cited and a few remarkable structures are discussed and illustrated. Ha(11c)

Repair to Stone Crusher Jaw. JAMES LYALL. *Welding*, Vol. 2, Mar. 1931, page 174.

A broken piece of cast iron 7 × 3½ in. and 8 in. long had to be replaced. Repair was done in 10½ hr. in a fairly out-of-the-way place. Ha(11c)

Welding Plates and Pressure Vessels. P. R. HAWTHORNE. *Welding*, Vol. 2, Feb. 1931, pages 89–92.

The author shows in several examples that by the use of proper welding methods, procedure control and method of annealing, welded vessels for high pressures are made stronger than riveted vessels. Such vessels should, however, always be annealed after welding; a car type annealing furnace is described. Ha(11c)

Tests on Arc-Welded Parts of Iron Structures. (Versuche an lichtbogengeschweissten Eisenkonstruktionen.) K. LIEDLOFF. *Die Schmelzschweissung*, Vol. 10, Apr. 1931, pages 99–100.

Communicated by the Lehr- und Versuchswerkstätten für Schweisstechnik, Charlottenburg. Description of 12 tests with welded structural iron parts as they were made by the Westinghouse Elec. & Mfg. Co. to obtain preliminary information for the welding of a 5-story building. Ha(11c)

Thermit-Welding Practice in England. E. DACRE LACY. *Welding*, Vol. 2, Mar. 1931, pages 177–179.

Special reference is made to the application of this method for rail joints. A series of tests is described. Ha(11c)

All-Welded Railway Fuel Tank. JAMES LYALL. *Welding*, Vol. 2, Mar. 1931, page 187.

A gas tank made of ½ in. plate, 6 ft. in diameter, 23 ft. 6 in. long. Longitudinal seams are butt-welded, circumferential seams are lap-welded. Ha(11c)

Oxy-Acetylene Welding Local Gas Lines. L. A. KIRCH. *Welding*, Vol. 2, Feb. 1931, pages 99–100.

Describes method of welding and testing 2 in. mains; it pays because of reduced maintenance cost and gas leakage. Ha(11c)

Develops New Technique in Electric Arc Welding. J. D. KNOX. *Steel*, Vol. 87, Oct. 9, 1930, pages 62, 65.

Describes work carried out at Barberton, Ohio, plant of Babcock & Wilcox Co. New type of electrode has been developed and a special arc-welding machine evolved. Weld metal contains 0.30–0.60% Mn, 0.08–0.15% C, and less than 0.04% S, 0.04% P and 0.02% N. Electrode produces a quiet and stable arc and causes practically no spattering of metal. Rod is mounted vertically in a feeding device which is self-propelled forward or backward by an adjustable speed motor. Steel drums must be annealed after welding operation. Weld metal had ultimate tensile strength of 65,000–74,500 lb./in.², yield-point of 40,000–55,000 lb./in.², elongation in 2 in. of 20.5–38%, reduction in area of 32–65%, and Charpy impact values of 20–45 ft.-lb. Rotating-beam tests indicated an endurance limit of about 30,000 lb./in.² Finished products are subjected to repeated pressure tests, X-ray examination and electromagnetic tests. MS(11c)

Influence of Pressure Conditions in the Oxy-Acetylene Burner on the Economy and Quality of the Weld. (Einfluss der Druckverhältnisse im Azetylen-Sauerstoff-Schweissbrenner auf die Wirtschaftlichkeit und Güte der Schweissung.) H. KEMPER. *Forschungsarbeiten auf dem Gebiete der Azetylen-Schweissung*, Jan. 1930, pages 53–83.

The tests were made with the following types of burners: (1) Injector burners with (a) low pressure gas, (b) high pressure gas. (2) Burners with mixing-nozzles or uni-pressure burners. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 851. Ha(11c)

Automatic Gas-Cutting of Irregular Shapes. THOS. D. KETCHBAW. *Welding*, Vol. 2, May 1931, pages 297–299.

The methods for laying out templets, cutting with flame, adjustment of gas pressures, etc., automatic cutting and speed of cutting used by the Santa Fe Railway are described. The speed of cutting can be considerably increased by pre-heating the material to about 1000° F. Ha(11c)

WORKING OF METALS & ALLOYS (12)

The Manufacture of Steel Sheets. E. S. LAWRENCE. Penton Publishing Co., Cleveland, 1930. Cloth, 6 × 9¼, inches, 233 pages. Price $6.15.

This book is written to give the interested layman, such as the purchaser of automobile sheets, some insight into the processes by which sheet is made. It is somewhat doubtful whether one with absolutely no metallurgical background could follow all the chapters without considerable mental effort. The experienced sheet mill metallurgist will probably consider the treatment rather elementary. Other metallurgists will find the book interesting and readable.

Lawrence characterizes box annealing as an unsound method of heat-treatment which will ultimately be displaced. He visualizes continuous strip rolling, followed by pack rolling on a sheet mill, then by continuous normalizing by a cycle that will be the equivalent of normalizing plus box annealing, and finally by pickling and cold rolling for surface, as the probable future method.—H. W. Gillett (12)-B-

Melting & Refining (12a)

Manufacture and Casting of Acid and Basic Open-Hearth Steel. DANIEL CLARK. *Transaction & Bulletin, American Foundrymen's Association*, Vol. 1, Feb. 1930, pages 22–35; Mar. 1930, pages 26–44; Apr. 1930, pages 18–29.

The paper was segregated into the following headings: historical; observations in the manufacture of producer gas; acid open-hearth steel in the furnace; basic open-hearth steel in the furnace; the casting of acid and basic open-hearth steel into (a) ingots, (b) foundry work; non-metallic inclusions, their occurrence and effect; and the relative merits of acid and basic open-hearth steel. CHL(12a)

Fundamental Facts on the Physical-Chemistry of Steel Making Processes. (Grundsätzliches über die physikalisch-chemische Untersuchung der Stahlerzeugungsverfahren.) F. SAUERWALD. *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 361–366.

Report 201 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The article gives a theoretical deduction of the methods which must be applied in studying the physico-chemistry of the steel making process, outlines the suppositions which must be fulfilled in studying equilibria and makes suggestions for further research. GN(12a)

Melts Iron and Steel in Electric Furnace. GILBERT S. SCHALLER. *Foundry*, Vol. 58, Aug. 15, 1930, pages 48–51.

Gray Fe superheated in electric furnace will produce castings having close grained structure with resistance to wear. Discusses results obtained by Lidgerwood Pacific Co., Tacoma, Wash., and describes equipment used. VSP(12a)

Production of High Grade Iron from Scrap in the Electric Furnace. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1353–1358.

York Ice Machinery Corp., York, Pa. produces high-strength irons in a 1-ton, rocking-type, indirect-arc furnace from a charge consisting entirely of scrap material, without the addition of any alloys. Metal is poured at 2800° F. Time from charging the furnace to pouring the metal ranges from 80–85 min. Electrode consumption is 5½ lbs. C per ton of iron melted. Power consumption averages about 560 kwh. per ton of metal melted. MS(12a)

High-Frequency Furnace Produces Pure Steel. RUDOLF HOHAGE & BERNARD MATUSCHKA. *Steel*, Vol. 87, Dec. 11, 1930, pages 55–56.

Translated from the *Schoeller-Bleckmann News*. Schoeller-Bleckmann A.-G. was one of the first European steel plants to install a high-frequency furnace. Such high efficiencies are attained that the process can compete with other steel manufacturing methods. A charge of about 660 lbs. is melted in slightly over an hour. Melting takes place in the absence of all detrimental gases. Due to the deoxidizing action of the Si from the melting crucible and to the uninterrupted, slow, automatic mixing resulting from the circulation created by the magnetic fields set up in the bath, the steel produced is unusually free from inclusions and is homogeneous throughout. Cleanliness of high-frequency crucible steel exceeds that of ordinary crucible steel. Points out the importance of this factor by briefly discussing the deleterious effects of inclusions. MS(12a)

The Reactions of Iron Sulphide, Manganese Sulphide and Calcium Sulphide with Iron Oxides. (Ueber die Umsetzungen von Eisensulfid, Mangansulfid und Kalziumsulfid mit den Oxyden des Eisens und dabei auftretende Nebenreaktionen.) E. DIEPSCHLAG & E. HORN. *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 375–382.

An analytical method was developed to determine Fe″ and Fe‴ in the presence of sulphides. The reaction $FeS + 10\ Fe_2O_3 = 7\ Fe_3O_4 + SO_2$ starts at 550° C. and is completed at 850° C. The occurrence of free ferrous oxide at temperatures up to 900° C. could not be substantiated, as it has been found by L. Wöhler and his collaborators. Excessive FeS starts to react with Fe_3O_4 at temperatures of around 1100° C., according to the equation $FeS + 3\ Fe_3O_4 = 10\ FeO + SO_2$. A total decomposition of iron oxides to ferrous oxides in the presence of excessive sulphide is achieved when the mixtures are heated to 1300–1350° C. The reaction $MnS + 9\ Fe_2O_3 = MnO + 6\ Fe_3O_4 + SO_2$ starts at 550° C. and is completed at 850° C. MnS and Fe_3O_4 reacted at 975° C. The reactions with CaS differ from the above reactions, inasmuch as the calcium ferrites formed are reduced to CaO and FeO by excessive CaS. With calcium ferrites for reduction substances, it was found that the ferrites react with CaS and FeS at temperatures of 800° C. After the reaction has taken place to a certain extent, the reaction velocity with CaS decreases, but rapidly increases again between 1150° and 1200° C. The formation of the compound $3\ CaO \cdot Fe_2O_3$ is assumed. This assumption is verified by the fact that mixtures of $3\ CaO + Fe_2O_3$ react at 1150° C. in a similar way as the above mixtures. None of the above reactions could be reversed. An explanation is given as to how the sulphur segregated during the experiments is formed. GN(12a)

Melting German Silver Alloys. JOSEPH P. MCGINNIS. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, page 556.

Gives formulas used by the author for German silver alloy castings. VSP(12a)

Quality Control, Alloy Contamination in Making Open-Hearth Steel. *Iron Age*, Vol. 126, Dec. 4, 1930, pages 1701, 1745–1746.

Taken from Cleveland meeting of the open-hearth operators, under the auspices of the American Institute of Mining and Metallurgical Engineers. Discusses some of the metallurgical and other features of open-hearth steel plants. VSP(12a)

The Scientific Production of Non-ferrous Ingots. WALTER H. JACOBSON & WILLIAM KELLY (Tottenville Copper Company, Inc.). *Metal Industry*, N. Y., Vol. 29, Apr. 1931, pages 149–151.

The various advantages of using brass and bronze ingots made from secondary metals under close chemical control and microscopic and macroscopic examination are mentioned. A table of the chemical specifications for 15 alloys recommended for non-ferrous ingots is given. PRK(12a)

Copper Refining. (Die Kupferraffination.) M. WAEHLERT. Wilhelm Knapp Verlag, Halle, 1927. Paper, $6^1/_2 \times 9^1/_2$ inches, 142 pages. Price 11.40 RM.

The author of this book on copper refining has been superintendent of the copper refinery of the Osnabrück Copper and Wire Plant, Osnabrück, Germany, for many years. He deals with his subject with authority, gained by a scientifically trained mind and a clear sense of finding facts.

The book covers the material designated by the following 8 chapters: raw materials, refining furnaces, charging of furnaces, process of refining, methods of casting, melting of slags in the cupola, lay-outs of plants, production costs. Among the subjects covered, the physical chemistry of the refining process takes the largest space (nearly 40 pages) which goes to show that the author endeavored to go back to the root of many troubles which copper offers in the processing to the finished product, such as fine wire. Certainly, the correlations between copper, oxygen, poling gases and impurities have a good deal to do with the quality, the process of crystallization and the surface conditions of the cast refined copper, which factors in turn affect the behavior in final processing to the finished product to a large extent. The author gives his own observations and evaluates them. This certainly is the most valuable accomplishment of the book which makes it worthwhile reading for every copper metallurgist.

In the appendix, a review of the literature on the subject is included.—G. Neuendorff (12a)-B-

Electric Furnaces for Steel Melting. N. R. DAVIS & C. R. BURCH. *Transactions, Manchester Association of Engineers*, 1929–30, pages 146–162.

Includes discussion. Deals chiefly with high frequency induction melting. A sketch of a 500 lb. steel furnace is shown. No difficulty is met from the active circulation in the furnace. Even without a quiescent period at the end of the melt, the furnace produces clean metal. A 10-ton furnace can now be designed with confidence. See also *Metals & Alloys*, Vol. 1, Mar. 1930, page 429. HWG(12a)

Operation and Metallurgy of a 200-Ton Tilting Furnace for the Talbot Method. (Betrieb und Metallurgie eines 200-t.-Kippofens für das Talbot-Verfahren.) W. ALBERTS. *Stahl und Eisen*, Vol. 51, Jan. 29, 1931, pages 117–128.

Report 200 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The investigation covers metallurgy and economics of a modern tilting furnace of 200 tons capacity. In particular, the occurrences during the deoxidation period with either solid or liquid ferromanganese have been studied. It could be proven that the deoxidation with molten ferromanganese is superior to the deoxidation with solid ferromanganese, as far as the effect is concerned. Mechanical tests on steels made according to the Talbot method show that this steel is not inferior to open-hearth steel made in other furnaces. Due to the fact that there is available a sufficient number of smaller open-hearth furnaces for making special steels, it seems advisable to build tilting furnaces for the Talbot method in the case of reconstruction of furnaces. GN(12a)

Investigations into the Chemical Processes of the Acid Steel Production Methods and of the Deoxidation of Steel by Manganese and Silicon. (Untersuchungen über die chemischen Vorgänge bei den sauren Stahlerzeugungsverfahren und bei der Deoxydation des Stahls mit Mangan und Silizium.) HERMANN SCHENCK. *Krupp'sche Monatshefte*, Vol. 12, Apr. 1931, pages 63–81.

The very close metallurgical similarity of the reactions of Mn and Si in the acid steel production processes and in deoxidation can be utilized to draw conclusions from one to the other. The theory of processes is developed in detail. For the determination of the equilibrium in the complex system, the knowledge of the equilibrium constants for the reactions $FeO + Mn \rightleftarrows MnO + Fe$ and $2FeO + Si \rightleftarrows SiO_2 + 2Fe$ and of the dissociation constants of the manganese- and iron-silicates are necessary. If 2 of the required quantities are known, the others can be calculated from tests on the open-hearth furnace or on the Bessemer converter. After a tabulation of numerical values at present available, determination of the constants of the afore-mentioned reactions by affinity calculation was attempted. The comparison of calculated constants with previous test results permits the conclusion that the calculated figures are sufficiently useful for judging the deoxidation with Mn or Si alone. All results are represented in the diagrams and calculated values tabulated. 55 bibliographical references. Ha(12a)

Casting & Solidification (12b)

The Structure of Cast Alloys. (Die Struktur von Gusslegierungen.) MARIE L. V. GAYLER. *Metallwirtschaft*, Vol. 10, Feb. 20, 1931, pages 141–144.

Contains 3 references. An aluminum alloy containing 7% copper was melted in a high frequency induction furnace and held in a vacuum, in presence of air, nitrogen, hydrogen and furnace gases for 25 minutes. One set was cast at 740° C. and another at 840°. Each heat was cast into 4 different molds: steel, graphite, water cooled copper and sand. Macrophotographs of the structures are shown. The furnace atmosphere has little effect on the specimens cast at 740°. The macrostructure in all is fine grained, in those melted in vacuum and under hydrogen the finest. Those cast in sand are somewhat coarser than those cast in steel. The microstructure is the same in all. The macrostructure of the set cast at 840° into steel molds is coarser than that cast at 740° and there is much more difference between different furnace atmospheres. Furnace gases produce the coarsest grain and the difference is still greater when cast in sand. The microstructure is finer grained at the higher casting temperature. Both series cast in water-cooled molds have a similar fine grained macrostructure, with little difference between the various furnace atmospheres. CEM(12b)

Aluminum Kitchenware Is Cast in Permanent Molds. J. B. NEALEY. *Foundry*, Vol. 58, Oct. 1, 1930, pages 86–87, 89.

Present-day production of Al or Al alloy castings is divided into three methods—sand casting, permanent mold and die casting. Permanent mold alloys of Cu, brass, etc., melting in neighborhood of 2000° F. are used. Describes method used by the Monarch Aluminum Ware Co., Detroit. Castings with almost any combination of physical properties are used, mostly Al. Most common alloy used contains 92% Al and 8% Cu. When poured this alloy develops tensile strength of 18,000 to 20,000 lbs./in.², yield point of about 16,000 lbs./in.² and an elongation of 2 to 5%. Another alloy contains 95% Al and 5% Si, having tensile strength of about 24,000 lbs./in.², yield point of 17,000 to 18,000 lbs./in.² and elongation of 4 to 5%. Still another consists of an Al base with Ni, Mg and Mn, developing a tensile strength of 35,000 to 40,000 lbs./in.². Several types of melting furnaces are used. Retort is split longitudinally. Gas fired furnaces used for annealing and heat treating. After material has been brought to temperature for heat treating it must be soaked for a certain period before quenching. VSP(12b)

Trend in Steel Ladle Design Toward Two-Stopper Units. Attributes Cracked Corners on Ingots to Preparation of Molds. *Steel*, Vol. 87, Nov. 27, 1930, pages 48–49.

Report of the 12th semi-annual meeting of the Open-Hearth Committee of the American Institute of Mining and Metallurgical Engineers, Cleveland, Nov. 20–21, 1931. Includes abstracts of discussion on questions other than those indicated by the titles. MS(12b)

Rolling (12c)

The Economical Application of Compressed Scrap in Open Hearth Practice. (Die Wirtschaftlichkeit der Verwendung von Paketschrott im Siemens-Martin-Betrieb.) J. PANZL & TH. DAHMEN. *Stahl und Eisen*, Vol. 51, Jan. 8, 1931, pages 47–49.

The authors give the results of preliminary tests on compressing low grade scrap in order to determine whether or not there is a possibility of rolling these scrap bars directly to muck bars. Though no structural uniformity can be obtained, it is noticeable that a tensile strength between 32.3 and 34.4 kg./mm.² with 12.7% to 25% elongation has been obtained with bars of the average composition: C: 0.035–0.06, Si: 0.01–0.10, Mn: 0.36–0.45, P: 0.019–0.044, S: 0.05–0.07. GN(12c)

Aluminium Sheet Production, Part V—Rolling Ingots. ROBERT J. ANDERSON. *Metallurgia*, Vol. 3, Feb. 1931, pages 137–140.

Bibliography of 26 references. Describes various shapes of ingots. The sizes vary from 20 to 20,000 lbs., but the majority of the sheet is produced from 50 to 150 lb.-ingots. Smooth surfaces are important. Some ingot defects are due to faulty melting practice. The crystal structure of ingots is a factor in sheet production. JLG(12c)

The Pass Design of Reducing Rolls for Seamless Tubes. (Die Kalibrierung der Reduzierwalzen für nahtlose Rohre.) P. GOROL. *Stahl und Eisen*, Vol. 51, Jan. 8, 1931, pages 33–37.

Report 82 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The economic superiority and the technical disadvantages of cross rolling processes are discussed. The disadvantages of this rolling method are that the wall thickness of the tube increases non-uniformly in passing through the passes, the material is frequently out of round; changing of the numerous rolls of this type of mill requires much time. To counterbalance these disadvantages, various remedies are discussed. In the first place, it is advisable to diminish the wall thickness by the amount it increases during rolling. The reduction from pass to pass must be much smaller than the average reduction in rolling full round shapes. The rolling speed must be equalized so as to obtain a tension between 2 subsequent passes. The passes should be made somewhat oval. Careful supervision of all individual parts of the mill is most essential for successful operation. GN(12c)

Building Forming Mill for 26-inch Welded Pipe. *Steel*, Vol. 87, Aug. 14, 1930, page 54.

Describes mill built by the Yoder Co., Cleveland, Ohio. Mill is of the 2-high continuous type, consisting of 12 stands and is designed to roll pipe 18–26 in. in diameter with wall thicknesses up to $^3/_4$ in. at a speed of 100 ft./min. First 5 stands are provided with horizontal rolls only, while the last 7 have both horizontal and vertical rolls. The rolls are of hardened and ground cast-steel. MS(12c)

Forces Acting on Roll-Neck Bearings. W. TRINKS & J. H. HITCHCOCK. *Rolling Mill Journal*, Vol. 4, Oct. 1930, pages 531–536; Nov. 1930, pages 623–628.

From paper read before the American Society of Mechanical Engineers, Sept. 22–24, 1930. See *Metals & Alloys*, Vol. 2, May 1931, page 106. MS(12c)

Modernization of Existing Hot Sheet Mills. R. J. WEAN (Wean Engineering Co., Inc.). *Rolling Mill Journal*, Vol. 4, Dec. 1930, pages 659–661.

Developments such as continuous pack- and pair-heating furnaces, mechanical feeders and catchers, and continuous hot-mill polishers have permitted conventional type sheet-mills to utilize present investment, maintain employment, and operate at a profit. MS(12c)

The Base Metal Rolling Mill of the International Silver Company. F. A. WESTBROOK. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, pages 551–553.

Describes the operations of rolling nickel silver and pewter. VSP(12c)

Overcoming Difficulties in Rolling Structural Shapes. HAROLD HARRIS. *Rolling Mill Journal*, Vol. 4, Oct. 1930, pages 553–555.

Discusses causes of cambering, finning and cobbling and methods of overcoming such difficulties. MS(12c)

Expansion and Contraction of Sheet and Tin Plate Mill Hot Rolls. HAROLD HARRIS. *Rolling Mill Journal*, Vol. 4, Aug. 1930, pages 431–433.

Discusses causes of roll breakage and their avoidance by proper rolling practice. Most frequent cause of breakage is overheating of the rolls, which results in excessive expansion. Another cause is the gagging of bars in rolls, which is due to backlash or too loose a top roll. Other causes are excessive draft and rolling with hot or dry necks. MS(12c)

Recent Developments in Cooling Table Construction. MAX CURTH. *Rolling Mill Journal*, Vol. 4, Dec. 1930, pages 691–694.

Concluding installment of a translated abstract of a report of the Walzwerksausschuss des Vereins deutscher Eisenhüttenleute. MS(12c)

Forging (12d)

Stainless Steel and Its Properties. CARL S. SMITH (Republic Steel Corp.). *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1403–1405, 1408; Condensed in *Steel*, Vol. 87, Oct. 16, 1930, pages 45–46; *Machinery*, London, Vol. 37, Dec. 11, 1930, page 360.

Paper read before the American Drop Forging Institute, Oct. 9–11, 1930. Cr steels are easily coarsened by heat, are brittle when cold unless properly treated or alloyed, and have poor heat conductivity. It requires 2–3 times more power to work these alloys than ordinary C steel. Most satisfactory surface for forging is turned bar stock. Important points to be observed are: Clean steel inside and upon the surface; heating cycles that provide for preheat below the grain growth range in the simple Cr steels and below the carbide precipitation in the Cr-Ni steels; rapid controlled heating from the preheat to the working temperatures and positive fast work while hot, keeping in mind that the cold working ranges begin much higher than in simple steels while the top temperatures for working are no higher; and scrupulous inspection for surface defects to insure that any trapped scale is removed. Cutlery is heated to 1800° F., quenched in oil and drawn. In the Cr-Ni steels, maximum corrosion resistance is obtained by heating rapidly to 2100° F. and quenching sections of more than $^1/_{16}$ in. in H_2O. This treatment prevents precipitation of carbides which lower corrosion resistance. Highest temperature during forging of Cr-Ni steels should be kept below 2350° F., to prevent precipitation of the δ-phase. MS(12d)

Extruding (12f)

Lead Wire, Its Manufacture and Use. J. A. McDonald. *Wire & Wire Products*, Vol. 6, May 1931, pages 174–175.

Description of production methods of the Northwest Lead Co., Seattle, Wash. The wire is mostly extruded from hydraulically operated presses at 500 to 1000 tons pressure. Lead pipes are also made in this way. Lead coating by spraying and burning of lead for joints is described. Ha(12f)

Machining (12g)

The New Alloys and Machine Tool Design. Part III. Francis W. Shaw. *Metallurgia*, Vol. 3, Feb. 1931, pages 131–134.

Discussion of multiple tools, efficient planning and use of inserted teeth cutters. JLG(12g)

The Influence of Different Methods of Finishing on the Structure of the Surface Zone in Cast Iron. (Ueber den Einfluss verschiedener Bearbeitungsverfahren auf das Gefüge in der Randzone von Gusseisen.) W. Schilken (Esslingen Maschinenfabrik). *Mitteilungen aus den Forschungsanstalten, Gutehoffungshütte Konzern*, Vol. 1, April 1931, pages 92–100.

Very rapid wear on well lubricated co-acting rings of an ammonia compressor, used instead of a stuffing box, made of 200 to 220 Brinell gray iron had to be overcome. Iron of 180 Brinell, hard iron, annealed iron, hardened steel and bearing metal were all tried with no better results. Hence the method of finishing was studied. Turning cast iron with tool steel, high speed steel, tungsten carbide tools, grinding, honing and lapping were studied. Microscopic examination of the surfaces indicated that tiny cracks extended down through phosphide areas to graphite particles, leaving pieces ready to break out, if the rings were turned in the usual way. Stresses are introduced through distortion by slow turning that results in cracks. It is concluded that a pearlitic structure, very fine graphite, preferably almost of the fineness of temper carbon, and absence of phosphide are required. Such a material, turned at high speed with tungsten carbide tools, gives a surface without cracks. The article is profusely illustrated, the illustrations taking as much space as the text. HWG(12g)

The Machining of Aluminum and Its Light Alloys. (Nota sur alcune questioni inerenti la lavorazione meccanica delle leghe leggere e dell' alluminio puro.) U. Magnani & C. Panseri. *La Metallurgia Italiana*, Vol. 9, Apr. 1931, pages 265–291.

This article contains 72 figures, 16 tables, 19 footnotes and 32 bibliographic references. Types of tools and tool angles, speeds and feeds for drilling, planing, milling, turning, tapping, cutting off and filing are discussed in detail for machining aluminum, the Al-Si alloys and the duralumin type of alloys, with some consideration given to electron, bronze, steel, cast iron, high silicon irons, Mn steel, etc. Tungsten carbide, stellite and diamond tools are touched upon, as are grinding wheels. So much of the information is given in the figures that the original should be consulted. HWG(12g)

Lubricants and Cutting Fluids. A. H. d'Arcambal. *Wire & Wire Products*, Vol. 6, May 1931, page 171.

Cutting of metals is done in the following ways: (1) dry, without any fluid, but sometimes with an air blast; (2) watery solutions, sometimes containing an alkali; (3) emulsions, soluble oils; (4) oils, i. e., fixed oils, mineral oils, compounded oils, sulphurized mineral oils. For general machining, except threading, sulphur base oil should be used. For lathe turning, emulsion oil with 20 parts of water is suggested. For threading amber fluid containing about 1% of sulphur is advised. Ha(12g)

New Tools Successfully Cut High-Manganese Steels. Walter R. Breeler (Whitman & Barnes, Inc.). *Steel*, Vol. 87, Aug. 7, 1930, page 67.

A twist drill made of Co high-speed steel has been developed for drilling Mn steel. The point is given a 68° angle, the cone angle is 120°, and the lip clearance, 6–8°. To strengthen the cutting edge, a flat section is ground on the lips. Drilling machine must have a positive feed and speed mechanism powerful enough to drive the drill through. Peripheral speed of the drill should be 12–15 ft./min. Hole should be drilled through in one continuous cut. On deep cuts, it is practical to drill the hole intermittently or to cool the drill in oil. MS(12g)

Regulation of Particle Size Promises Added Strength. W. H. McCoy (General Motors Corp.). *Steel*, Vol. 87, Oct. 16, 1930, pages 48, 55.

Paper read before Society of Automotive Engineers at Detroit, Oct. 7–8, 1930. See "The Future of Tungsten Carbide as a Cutting Tool," *Metals & Alloys*, Vol. 2, Feb. 1931, page 43. MS(12g)

Drawing & Stamping (12h)

Ford Rustless Steel Radiator Shells Need 17 Press Operations. J. Geschelin. *Automotive Industries*, Vol. 63, July 12, 1930, pages 44–46, 48.

Illustrated description of the finishing operations of Allegheny metal parts used in the Ford cars. GN(12h)

Production Determines Value of Tungsten Carbide Dies. H. R. Simonds *Steel*, Vol. 87, Aug. 28, 1930, pages 50–51.

Igoe Bros., Newark, N. J., uses three types of dies: (1) 18-hole draw-plate made of high-grade forged steel containing 18% Cr and a small amount of Ni; (2) cast blocks of high-grade, high-C Fe, chilled in the mold, with 12–15 holes; and (3) single-hole block made of high-C steel and lined with tungsten carbide. The last draws 1/4 in. low-C wire rod down to 0.199-in. wire in one operation. A single die produces approximately 200,000 lbs. of wire and gives a better finish to the product. The initial cost of the tungsten carbide die is, however, 6 times that of the forged-steel plate, and the grinding costs are much higher. MS(12h)

Carbide Dies Advancing the Art of Wire Drawing. L. D. Granger (Wickwire Steel Co.). *Iron Age*, Vol. 127, Jan. 1, 1931, pages 40–41.

Application of tungsten carbide in continuous wire drawing, with careful study of angles, bearings, reduction and lubrication have made wire drawing a more exact process. Advantages include increased production, lower power costs and reduction in mill rejections. Carbide dies must be of suitable grade, of proper shape and have sufficient material to withstand stresses without breakage. VSP(12h)

The Dick Pressing Process and the Inverted Pressing Machines. (Das Dicksche Pressverfahren und die umgekehrt arbeitenden Pressen.) O. Busse & Cl. Busse. *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 105–113.

The paper was presented before the Deutsche Gesellschaft für Metallkunde, Berlin, 1930. The replacement of the rolling process by mechanical and hydraulic pressing operations is considered and the historical development of the latter reviewed. The direct and inverted processes are critically discussed and the results of an all-round inquiry concerning the experiences of the various plants are given. The advantages of the inverted process are emphasized. Includes discussion. EF(12h)

Forming of Metals. (Spanlose Formung der Metalle.) G. Sachs. Julius Springer Verlag, Berlin, 1931. Cloth, 8 1/2 × 11 3/4 inches, 127 pages. Price 28 R. M.

This is a collection of articles by Sachs and co-workers on the forming of metals without cutting, i. e., by inducing plastic flow.

They relate to deep-drawing, wire-drawing, extrusion and to indentation methods of hardness testing. The mechanics of the processes are considered in detail.

Much more attention seems to be given to the fundamentals of these forming processes in Germany than in any other country so far. At least, the publications from other than German sources are very rare. The work of Sachs and his co-workers deserves careful attention, hence this volume should be of interest to many American readers.

The articles will appear also in Sonderheft 16 of *Mitteilungen der deutschen Materialprüfungsanstalten*. The individual articles will be abstracted, instead of discussing the whole group of articles here.—H. W. Gillett (12h)-B-

Construction of the Metal Airplane. G. H. Prudden (Keystone Aircraft Corp.). *Preprint* for May 1931 meeting, Aeronautic Div., *American Society of Mechanical Engineers*, 6 pages.

The author predicts very much lower cost in the construction of metal planes, although in the past this cost has been high due to small production of any one model. Dies for quantity production of formed metal parts are extremely expensive, and while it has been recognized that when production is large enough to allow distributing this die cost, metal construction will be cheapest, with present outputs the cost of ordinary die processes is prohibitive. The author, however, by "re-discovering" the soft metal die process, has opened the way to dies cheap enough so that the hand forming process can be beaten in cost even though only a few pieces are to be made. A clay pattern is swept up and modeled. From this a plaster cast is made, which serves as the pattern for a cast Zn die. This die is aligned under a drop hammer, and a Pb base cast around it which locates it as to holes in the anvil. The other half of the die is made in place under the hammer by building a dam about the lower half, pouring on antimonial lead, and lowering the hammer to meet it. The clearance is obtained by inserting a black iron sheet of the same thickness as the duralumin to be stamped and stamping that, which forces the clearance into the soft metal. Or a Zn casting is made with the lower half as the pattern, shrinkage producing the clearance. Such a casting of the upper half is then fastened onto the hammer with lead as before. As compared with hand forming, this plan has saved 30% of the man hours in the fabrication of a metal plane. HWG(12h)

Electric Equipment for Wire Drawing. T. R. Rhea. *Wire & Wire Products*, Vol. 6, May 1931, pages 165–170.

Discusses in detail the various types of motors suitable for wire drawing machinery and their control. Ha(12h)

Cold Working (12j)

Treatment of Cold-Rolled Non-Ferrous Metals. (Behandlung kaltgereckter Nichteisenmetalle.) W. Wunder. *AEG-Mitteilungen*, Vol. 4, May 1931, pages 331–335; *Metallwirtschaft*, Vol. 10, May 1, 1931, pages 357–359.

Although it has long been known that cold-rolled non-ferrous metals, in some cases, become defective after some time, proper means are often not employed during manufacture to guard against losses of this kind. It is pointed out that cold-rolled material must, in any case, be heated to a temperature below the lower recrystallization temperature to protect them against forming cracks and to give them the best resilient qualities. A number of illustrations show materials which have developed such defects after cold-rolling. CEM+Ha(12j)

Strain Hardening of Some Materials during Cold Rolling. (Die Verfestigung einiger Werkstoffe beim Kaltwalzen.) E. Greulich. *Zeitschrift für Metallkunde*, Vol. 23, Mar. 1931, pages 91–93.

The exponential function which was found to govern the strain hardening of steels and Monel metal in relation to the deformation, could also be ascertained in case of Fe, Cu and brass (70/30) down to deformations by rolling of 30%. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 44. EF(12j)

High Edge or Flat Edge Straightening of Rails? (Hoch- oder Flachkantrichten der Schienen?) A. Lobeck. *Stahl und Eisen*, Vol. 51, Jan. 29, 1931, pages 128–129.

In investigating the various methods of straightening rails, it was found that the high edge straightening unfavorably affects foot and flange of the rail. Flat edge straightening is more favorable. GN(12j)

Cleaning (12k)

The Water Cleaning of Castings. (Das Gussputzen nach dem Wasserstrahlverfahren.) C. Gertreudts. *Giesserei Zeitung*, Vol. 27, Dec. 1, 1930, pages 633–636.

The cleaning of castings by means of high-pressure water offers essential economic advantages. GN(12k)

Removes Scale from Surface of Metal without Pitting. H. R. Simonds. *Steel*, Vol. 87, Nov. 6, 1930, pages 61, 63.

Describes Bullard-Dunn process for electrochemical cleaning of steel. Work to be cleaned is immersed for several minutes in a tank containing a solution of H_2SO_4, HCl and NaCl, given a quick wash in hot water, and immersed in an alkaline bath. Both the acid and alkaline tanks are equipped with means for electrifying the bath. The anodes are suspended along the sides, while the parts to be cleaned hang from heavy Cu cathodes at the center. All the electrodes in the acid tank are of Pb. In the alkaline tank, half the electrodes are Pb and the other half, Fe. Current of 60–100 amp./ft.^{2} at 6 volts is used. A clean Pb coated surface is produced in less than 5 min. The alkaline tank is equipped with a reversing switch which changes the direction of the current for the removal of the Pb coating, when desired. Pb coating protects steel from attack by acid. MS(12k)

Polishing & Grinding (12l)

Mechanical Methods for Producing a High Polish. (Das mechanische Hochglanzpolierverfahren.) Karl Becker. *Deutsche Goldschmiede-Zeitung*, Vol. 34, Apr. 11, 1931, pages 157–158.

A discussion of metals and machines used for polishing gold and silver ware. JLG(12l)

New Plant Can Polish 30 Tons of Chrome-Nickel Sheets Daily. E. F. Ross. *Steel*, Vol. 87, July 24, 1930, pages 43–45, 58.

Describes equipment and operations at the plant of the Republic Steel Corp., Massillon, Ohio. Equipment can handle normally sheets 60 in. wide and 168 in. long in thicknesses from 25 gage down to 1/4-in. plate. Sheets are first rough ground on machines equipped with a No. 80 abrasive belt, speed being 1400–1650 ft./min. Polishing is done on machines equipped with oscillating rolls 18 in. in diameter, coated with No. 100–220 abrasive, depending upon the surface finish desired. Speed is about 350 r. p. m. Special finishes can be supplied also. After polishing, the sheets are cleaned thoroughly by rubbing down with whiting. Sheets intended for exterior use are cleaned and pickled for 30 min. in 20–25% HNO_3 at 130° F. Pickling tanks are made of welded 18–8 Cr-Ni steel. MS(12l)

Diversity of Advice Clouds Problem of Polishing Stainless Steel. F. W. STURDEVANT. *Steel*, Vol. 87, Dec. 25, 1930, pages 48–49.

Original surface should be smooth in order to obtain mirror finish. Small articles are readily buffed with a fine count buffing wheel at a peripheral speed of 10,000–15,000 ft./min., cutting down with special composition made for the purpose and coloring with Cr_2O_3. Abrasive should be absolutely uniform and free from slivers and flats. Tallow or lard oil should be used on the wheels with each operation. For preparing surfaces to be buffed, a 14 in. soft muslin wheel, at 1750 r. p. m. with suitable grit is used. On some makes of wide sheets, nos. 80, 120, 150 and 180 abrasives are used in sequence. The sheets are then brushed with a Tampico wheel, with No. 200 emery cake applied locally, buffed and colored. Cutlery after being ground is passed between 2 polishing wheels of the compress type. Automatic mirror finishing machines are now used for buffing the blades. MS(12l)

The Grinding of Tools with Cutting Edges of Krupp's Tool Metal "Widia." (Ueber das Schleifen von Werkzeugen mit Schneiden aus Kruppschem Werkzeugmetall "Widia".) BRUNO LEDER. *Krupp'sche Monatshefte*, Vol. 12, Mar. 1931, pages 39–56.

The cutting capacity of the metal "Widia" depends, to a very great extent, on the proper shape of the cutting edge and its exact grinding. A table gives the cutting angle and the angle of the cutting edge for various hard metals. Numerous illustrations show the machines and methods for proper grinding of millers, planers, drills, etc. Ha(12l)

An Experimental Study of Metal Polishing by Flexible Polishing Wheels. EDWIN M. BAKER & GEORGE E. HOLBROOK. *American Electrochemical Society, Preprint* 59–31, April 1931 meeting, 16 pages.

This paper describes the apparatus which was designed and built at the University of Michigan for the experimental study of metal polishing by flexible polishing wheels, outlines the general procedure of the laboratory tests, and presents experimental data which were obtained in a study of the following problems: The determination of the effect of variations in pressure upon the performance of the wheels; the determination of the effect of variations in grain screen analysis and glue concentration upon performance; the determination of the changes of performance of a wheel as it is used in the polishing process; and the determination of the effect of applying a thin film of glue to the periphery of the wheels after all the grain has been applied. (12l)

Coloring (12m)

Process for Coloring Aluminum. *Brass World*, Vol. 27, Apr. 1931, page 82.

The process for finishing aluminum products in a variety of colors is described in literature of the Aluminum Coloring Corp., Indianapolis, Ind., operators of the "Alumilite" process under license of the Metals Protection Corp., Indianapolis, Ind. Color coatings which consist of a dyed oxide film 0.0004" thick, are hard and quite resistant to abrasion, this resistance being more than five times greater than five coats of baked enamel. WHB(12m)

DEFECTS (13)

Hot Cracks in Cast Steel. (Ein Beitrag zur Warmrissbildung an Stahlgussstücken.) K. SINGER & H. BENNEK. *Stahl und Eisen*, Vol. 51, Jan. 15, 1931, pages 61–63.

After considering the literature on the formation of cracks in cast steel, practical examples are dealt with. The possibility of closing cracks which originate during the solidification is proved by microscopic examinations. The process of shrinkage has been studied as well as the stresses which are set up in various cross-sections. A remedy for avoiding cracks is the proper regulation of the cooling conditions. GN(13)

Fatigue Failures. *Automobile Engineer*, Vol. 20, July 1930, page 254.

Brief general discussion of the effect of sharp angles, keyways, stamped inspection numbers and notches on the fatigue failure of metals. RHP(13)

The Causes of Some Defects Observed on Brewery Apparatus of Aluminum. (Ueber die Ursachen einiger an Aluminium-Brauereigefässen beobachteten Schäden.) G. ECKERT. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Nov. 1930, pages 191–194.

Most failures are due to unsuitable material, defective erection and improper use of the apparatus. The first reason is almost eliminated nowadays as aluminum can be produced with a very high degree of purity. The other reasons are discussed and means for their elimination described. Ha(13)

Preventing Defects in Brass Castings. WILLIAM J. REARDON. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, page 554.

Examination of defective casting showed shrinkage at the place where it leaked. Cause of defect was that heavy sections stay fluid longer than thin sections and light sections draw the metal from the heavy sections. Examination of another casting showed that it was spongy. This was caused by filling mold with metal of incorrect temperature, by core giving off too much gas and by incorrect melting of metal. Suggests remedies. VSP(13)

The Inverse Segregation in Aluminum-Copper Alloys. (Ueber die umgekehrte Blockseigerung von Aluminium-Kupfer-Legierungen.) H. BOHNER. *Aluminium, Hauszeitschrift der V. A. W. Erftwerk*, Vol. 3, Jan.-Mar. 1931, pages 3–19.

Certain aluminum alloys which solidify as solid solutions over a larger temperature range have the tendency to an inverse segregation, i. e., in such castings, the outer part has a higher, and the center a lower, percentage of the alloyed material than would correspond to the actual composition of the alloy. In a normal segregation, conditions are reversed. The paper, after exhaustive experiments, discusses the reasons for such phenomena as are dependent on composition of the alloy; conditions of casting and pouring; temperature of the metal and molds; pouring velocity; heat conduction, which exerts the greatest influence; and dimensions of the mold. The chemical and metallographic examination of the test pieces show a certain regular influence of composition and velocity of solidification. To obtain a satisfactory casting and to avoid segregation and also pipes, the Fe content must be less than 0.5%. The additions of Mn, Si and Ti must not exceed certain percentages as otherwise, in the center of the casting, larger and more brittle segregations of crystals take place which have a harmful effect on further working. The experiments will be continued particularly with regard to the influence of great velocities of solidification. Ha(13)

Cause of Rail Fractures. (Beitrag zur Klärung der Ursache von Schienenbrüchen.) H. BERCHTENBREITER & F. DOLL. *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 85, July 1930, pages 225–229, 17 illus.

Investigations on a large scale disclosed the influence of wheel pressure upon rail fractures. The presence of surface defects on the rail-base is stressed and the influence of low temperatures discussed. EF(13)

Why Metals Fail. H. F. MOORE. *Product Engineering*, Vol. 2, Apr. 1931, pages 164–166.

A general discussion of strength of metals and the reason for defects and the means of detecting defects. Ha(13)

Failure of Machine Members. L. T. HOLT. *Machine Design*, Vol. 3, June 1931, pages 41–43.

In the opinion of the author, notch fatigue, insufficient heat treatment and tool marks are some of the principal causes of failure. Inclusions and segregations of phosphorus are usually found in defective pieces; micrographs of several samples show such conditions. Ha(13)

CHEMICAL ANALYSIS (14)

Analysis of Remelt Aluminum. *Metal Industry*, N. Y., Vol. 28, Dec. 1930, page 553.

Describes results of a meeting of chemists representing members of Aluminum Research Institute at Cleveland to consider progress made to establish method of analyzing remelt Al and its alloys. VSP(14)

Some Observations on the Estimation of Silicon in Pig and Cast Iron. H. W. KEEBLE. *Iron & Steel Industry & British Foundryman*, Vol. 3, Sept. 1930, pages 367–368.

Methods for determining silicon in pig iron and gray and malleable iron castings; analysis is modification of Brown's method using sulphuric acid. CHL(14)

Different Methods of Determining Sulphur in Steels. (Différentes méthodes de dosage du soufre dans les aciers.) A. GUEDRAS. *Aciers Speciaux, Métaux et Alliages*, Vol. 6, Feb. 1931, pages 75–80.

This method is based on the same principles as determining carbon by combustion in oxygen atmosphere. The furnace is kept at 1200° C., a 2 g. sample placed in the furnace, a current of O_2 passed over the sample and the SO_2 gas is absorbed in H_2O_2 and NaOH solution which is titrated with H_2SO_4. GTM(14)

The Preparation of Pure Electrolytic-Nickel. Part III. Chemical and Physical Properties. COLIN G. FINK & F. A. ROHRMAN. *American Electrochemical Society, Preprint* 59–37, April 1931 meeting, 10 pages.

After having prepared samples of purified Ni as described in the first two parts of this research, it was necessary to analyze them for any impurities that might not have been removed. The ordinary scheme of chemical analysis could have been followed in two ways: the purity of the Ni might have been determined directly by a careful Ni analysis and the impurities found by difference, or the impurities could have been determined directly. The former requires specialized technique of extreme accuracy, and the latter would be an almost hopeless task. Normally, chemical means are not specific and require reagents, the purity of which cannot always be guaranteed. On the other hand, spectrographic analysis, especially in the case of the metals, is specific and requires no reagents. Another great advantage of spectrographic analysis is that it records the metallic impurities, expected or otherwise, and gives a permanent record of the analysis. (14)

Possible Use of the Poulsen Arc as a Means of Detecting Traces of Impurities in Metals. HARRY E. REDEKER & PHILIP A. LEIGHTON. *Journal American Chemical Society*, Vol. 52, Oct. 1930, pages 4169–4170.

Results of preliminary tests show that the use of the Poulsen arc serves as a means of detecting small traces of impurities of even atomic number in such metals as Cu, Au and Ag. MEH(14)

Handbook of Chemical Microscopy. Vol. 2. Chemical Methods & Inorganic Qualitative Analysis. E. M. CHAMOT & C. W. MASON. Wiley & Sons, New York, 1931. Cloth, 6¼ × 9¼ inches, 411 pages. Price $4.50.

Time is worth saving, in qualitative chemical analysis, as in any other technical operation. Occasions arise from time to time in which an analysis is needed on material too scanty in amount for an analysis by ordinary methods. The skilled chemical microscopist can, for example, rub off from an alloy sample an almost weightless streak on a fragment of unglazed porcelain, dissolve that trace of alloy, place a tiny drop of the solution on a microscope slide, add a suitable reagent, and in a twinkling tell with certainty from the appearance under the microscope of the crystals formed whether a certain metal sought is present or not. The convenience of the microchemical method makes it of great value wherever qualitative analysis is required.

Professor Chamot is the greatest living authority in this field, and most Americans skilled in it have gotten their skill directly from his instruction, or from being taught by those whom he has instructed. The methods deserve even wider use and appreciation. Chamot's previous book helped toward this, and the present edition by himself and his disciple, Mason, will help still more. It contains some 160 photomicrographs of the crystals produced by the reactions used, just as one sees them under the microscope, together with details of the micro-manipulation and discussion of the reactions involved.

The authors point out the limitations of the methods and do not claim a bit more for them than is deserved. Interferences by other elements than the one sought are pointed out. In many cases, however, the reagent used is specific; when it produces a given sort of crystal, it shows that the one element sought is present. This is in great contrast to the complex separations so often necessary in the usual schemes of qualitative analysis, and is the reason for the vast time saving realized when the micro method is applicable.

Many years of patient work were required to establish the conditions under which reliable specific tests are possible. The fruit of these many years of labor is given in this book.

It is unlikely that the average chemist could become a really skilled microanalyst by merely studying the book without some other instruction, but with a few weeks training such as is given by Chamot and Mason in summer school, he could, with the help of this book, handle almost any microchemical problem. It would pay many a firm to give some one of their analysts such training. It is to be hoped that many other universities will follow the lead of Cornell, now that such a complete text-book is available, and introduce a course in micro-analysis, so that a greater number of competent microanalysts will be trained.

The reviewer took the course under "Chammy" 25 years ago, and still classes it as one of the most interesting and useful courses ever offered to the chemist. His own observations of the applications of micro-chemistry lead him to believe that every metallurgical laboratory should have at least one analyst skilled in micro methods. The methods, and this book describing them, are most highly to be recommended.—H. W. Gillett (14)–B–

The Application of the Potentiometric Analysis in Steel Mill Laboratories. I. The Determination of Manganese, Chromium and Vanadium. (Die Anwendung der potentiometrischen Mass analyse im Eisenhüttenlaboratorium. I. Die Bestimmung von Mangan, Chrom und Vanadin nebeneinander.) P. DICKENS & G. THANHEISER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 14, 1930, Report 158, pages 203–223.

The principles of potentiometric titration, the most common methods and the manifold possibilities of application are considered. See *Metals & Alloys*, Vol. 1, July 1930, page 634. GN(14)

The Limits of Determination of Some Heavy Metals by Drop Reaction with Dithizone. (Die Erfassungsgrenzen für den Nachweis einiger Schwermetalle durch Tropfenreaktion mit Dithizon.) H. FISCHER. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 99–107.

Dithizone (Diphenyl-Thiocarbazone) has proved to be quite remarkably well suited for the qualitative recognition of very small quantities of heavy metals which, for most purposes of the analytical practice, is entirely sufficient. This is due to vivid coloring and the ready solubility in organic solvents, though insoluble in water. The following sensitivities were found: for Zn, 1:2,000,000; Cu, 1:1,660,000; Ag, 1:1,000,000; Pb, 1:1,250,000; Co, 1:1,250,000 (all in neutral solutions); for others, the sensitivity is smaller but still very pronounced. The method is especially suitable for micro-chemical work. Ha(14)

HISTORICAL & BIOGRAPHICAL (15)

From Welding Craftsmanship to Welding Technique. (Von Schweisshandwerk zur Schweisstechnik.) OTTO MIES. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 50–51.
An historical review of the development of methods and apparatus, and a program for future progress. Ha(15)

Dr. Herty Discusses Steel-Making. *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, page 1610. **Chemistry Aids Steel-Making Processes by Determining Substances in Steel.** *Steel*, Vol. 87, Sept. 4, 1930, page 45
From a report by C. H. Herty, Jr. to the Iron & Steel Section of the National Research Council Science Advisory Committee, which is working on plans for an iron and steel exhibit at the Chicago World's Fair in 1933. Outlines history of scientific investigations on steel-making processes. From 1860 to 1877, considerable attention was given to gases in steel. Much work was done on dephosphorization from 1877 to 1899. During 1889 to 1902, desulphurization received a great deal of attention. The effects of O in steel began to be appreciated and investigated during 1902 to 1912. Further investigations of O in steel were made and new methods devised for the determination of oxides during 1912 to 1922. From 1922 to 1930, increasing attention was paid to O in steel, with particular emphasis on the various types of O compounds present. MS(15)

Origin of Stainless Steels and Alloys. J. FERDINAND KAYSER (Darwin's, Ltd.). *Metallurgia*, Vol. 3, Feb. 1931, pages 135–136; *Steel*, Vol. 89, Mar. 19, 1931, page 55.
From a lecture to the Rotherham Technical Institute Engineering Society. Briefly reviews development of stainless alloys. JLG(15)

Investigation of Pre-Roman Raw Steel. (Untersuchung von Rohstahl aus der vorrömischen Zeit.) H. HANEMANN. *Stahl und Eisen*, Vol. 51, Jan. 15, 1931, pages 67–68.
A lump of raw steel dated from the La Tène period was examined metallographically and chemically. Forging tests indicate that the working of this steel must have offered difficulties. This piece of steel, over 2000 years old, shows the stability of cementite. GN(15)

ECONOMIC (16)

Zinc Industry in Poland. *Metal Industry*, London, Vol. 37, July 4, 1930, page 10.
Poland occupies third place in the world's production of Zn. Chief center of production is upper Silesia, which supplies about 85% of the total output. Home consumption is about 20%. Germany uses about 1/2 of the total Zn exported from Poland. VSP(16)

Steel Residences—Is This Market Appreciated? *Steel*, Vol. 87, Oct. 16, 1930, pages 50, 53, 55; Oct. 23, 1930, pages 57–59; Oct. 30, 1930, pages 54–55.
Outlines history of steel-frame construction for residences, describes the promotional program of the Steel Frame House Co., and draws conclusions as to the market possibilities of the future. On the basis of an average of 9 tons of steel per house, it is estimated that the total possible market for structural steel would be 2,700,000 tons annually. MS(16)

The Cycles of Prices of Non-ferrous Metals. LUDWIG VOGELSTEIN. *Bulletin* 216, *Mining & Metallurgical Society of America*, Jan. 1931, pages 2–17.
The Chairman of the Board of the American Metal Co., Ltd., first clarifies the meaning of generally loosely-employed terms such as business cycles, boom and depression times, etc., and lays stress on the fact that the cyclical movement of metal prices, production and consumption, is closely bound up with general business conditions; also that the argument that high prices do not check consumption is fallacious. Cyclical movements in the field of economics can defy temporarily the laws of demand and supply. The importance of the quantitative gold theory is exaggerated by those who favor it. 8 metal price and consumption charts are given and discussed in detail. MFB(16)

Group Research Among Gold Producers. R. M. P. HAMILTON. *Engineering & Mining Journal*, Vol. 131, Apr. 27, 1931, pages 356–358.
A plea is made for coöperation in the attainment of a greater standardization of technical efficiency and economical operation among the gold producers in Northern Ontario, along the lines of the successful effort in this direction in the Witwatersrand district, Transvaal and along the Golden Mile in Western Australia. Direct operating costs and metallurgical results of nine mills are tabulated and a flow sheet shown for a 500-ton combination flotation and cyanide plant. Some of the successes of the group research plan in the Transvaal and in Western Australia are touched upon. WHB(16)

Compensating Grinding Costs for Varying Billet Size. L. C. GRIFFIN (Precision Grinding Wheel Co., Inc.). *Steel*, Vol. 87, Aug. 28, 1930, pages 54, 56.
Outlines practical method by which the tonnage ground in the billet grinding departments can be figured on a fairer basis. Points out the importance of billet size in the computation of grinding costs. Method is based on the fact that a billet 4 × 4 of any length has the same number of sq. in. grinding area as it has cu. in. volume. When grinding any other size billet, the actual weight of the billet should be multiplied by a factor, $\frac{\text{sq. in. grinding area}}{\text{cu. in. volume}}$ to obtain the weight which should be credited to the grinding room. MS(16)

Billet Sizes Regulate Grinding Costs. L. C. GRIFFIN (Precision Grinding Wheel Co., Inc.). *Steel*, Vol. 87, Sept. 18, 1930, page 54.
Explains how to apply author's method of computing grinding costs when various sizes of billets are ground. MS(16)

Budgeting Reduces Steel Plant Labor Turnover. L. C. EDGAR (Carnegie Steel Co.). *Steel*, Vol. 87, Sept. 25, 1930, pages 45–46.
From *Proceedings of the Engineers' Society of Western Pennsylvania*. MS(16)

Japan Seeking Recognition in Steel Production. G. H. AUPPERL (Tobatta Foundry Co.). *Steel*, Vol. 87, Dec. 4, 1930, pages 65, 67.
Japan now consumes about 2,550,000 metric tons of steel annually and exports more than 200,000 tons. Since 1907, demand has increased 5.5 times while producing capacity has increased 20 times. Three leading steel plants and the most important foundry have employed American and German consultants. About 60% of the equipment in these plants was manufactured in America and the balance was imported from Germany. The principal plant, the Imperial Steel Works, is owned and operated by the Japanese Government. It produces more than 1,000,000 tons of ingots annually. Gives some information about this plant and the Fukiai Works of the Kawasaki Dockyard Co. Bulk of raw material is imported. MS(16)

Some Fundamentals of Ship Pipe Welding. S. MATHESON. *Welding*, Vol. 1, July 1930, pages 596–598.
Economies could be obtained by replacing all screw fittings by welded pipe bends. Ha(16)

PLANTS & LABORATORIES (17)

Die-Casting in the Midlands. The Works of Metal Castings, Ltd., Worcester. *Metal Industry*, London, Vol. 38, Mar. 13, 1931, pages 285–288.
A description of the works of the pioneer company in Great Britain to successfully manufacture pressure die castings in both light and heavy alloys. PRK(17)

Die Casting in Birmingham. *Metal Industry*, London, Vol. 37, Oct. 17, 1930, pages 361–363.
Describes works of Messrs. F. H. Adams (1926) Ltd. VSP(17)

Canada's New Refining Capacity. *Metal Industry*, London, Vol. 38, Apr. 17, 1931, pages 414–415.
A description of Ontario Refining Company's plant at Copper Cliff, the capacity of which is 120,000 tons per year. The capacity of the Canadian Copper Refiners, Ltd., plant at Montreal is 75,000 tons per year. PRK(17)

Recent Design of Quicksilver Plants. C. N. SCHUETTE. *Engineering & Mining Journal*, Vol. 131, Apr. 13, 1931, pages 316–318.
Activity in the mining of quicksilver has been well sustained and has resulted in several changes in equipment and metallurgy of reduction plants. Three types of furnaces are in common use—the old Scott furnace, the rotary kiln and the Herreshoff furnace. The Scott is unsuitable to intermittent operation and requires a reasonably dry feed. The Herreshoff furnace has the advantage of a higher fuel economy than the rotary kiln and no occasional shutdowns for relining are necessary. Dust elimination is discussed and several illustrations from installations at different mines are shown. WHB(17)

Continuous Cast-Iron Testing in the Engine Foundry of the Fried. Krupp Aktiengesellschaft. (Ueber laufende Gusseisenprüfung in der Landmaschinengiesserei der Fried. Krupp A. G.). W. STRUK. *Krupp'sche Monatshefte*, Vol. 12, Apr. 1931, pages 89–92.
This company occupies a special foundry laboratory for very close supervision of the production of cast-iron, malleable as well as gray iron. The equipment of the laboratory and the methods of testing and representation in diagrams of the tests made are described and illustrated. Ha(17)

Aims at Perfection in Malleable Castings. *Foundry*, Vol. 58, Dec 1, 1930, pages 66–71.
Describes new plant of the Columbia Malleable Castings Co., Columbia, Pa. VSP(17)

Reduces Production Costs with a New Steel Foundry. *Foundry*, Vol. 58, Dec. 15, 1930, pages 44–47, 59.
Describes the equipment and operation of recently erected foundry of the Lebanon Steel Foundry Co., Lebanon, Pa. VSP(17)

Fabricates Chemical Tanks from Chromium-Nickel Alloys. H. R. SIMONDS. *Steel*, Vol. 87, Sept. 25, 1930, pages 43–44, 60.
Describes manufacture of tanks made of 18% Cr and 8% Ni steel as carried out by the Downingtown Iron Works, Downingtown, Pa. Both riveted and welded tanks can be produced satisfactorily when the structure is uniformly austenitic. Riveting practice follows closely that required for careful work with C steel. Rivets are driven at temperatures of 1850–2100° F. A hydraulic riveter is used wherever possible. Both oxyacetylene and electric welding are used. Welding-rod material is similar to that of the base metal. Bare rods are used for oxyacetylene welding and coated rods for arc welding. MS(17)

Finishing 10,000 Pocket Knives Daily. H. R. SIMONDS. *Steel*, Vol. 87, Dec. 4, 1930, pages 43–46.
Describes manufacture of pocket-knives by Remington Arms Co., Bridgeport, Conn. Nearly all operations are on automatic or semi-automatic machines. Blades made from steel sheets containing 1.10% C. MS(17)

Steel Works of the Mannesmann Tube Works, Dep. Schulz-Knaudt, Huckingen. (Hüttenwerkanlage der Mannesmannröhren—Werke Abt. Schulz-Knaudt, Huckingen.) PAUL STERN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Dec. 13, 1930, pages 1689–1695.
A very detailed description of the steel plant comprising conveyors and storage equipment, sintering plant and 2 blast furnaces of 500 tons each in 24 hrs. The blast furnace gas is cleaned electrically in an Elga cleaner. 4 basic Bessemer converters and six 50-ton open-hearth furnaces are provided for steel production. The new steel is semi-finished in 4 rolling mills. A water gas welding plant can make cylindrical tanks of 50 ft. in length and plates of 2 3/4 in. The gas cleaners are for 275,000 m.³/hr., the initial dust contents of 18 g./m.³ is reduced to 0.02 g./m.³; heating value of the gas is 900 to 1000 kgcal./m.³ See also *Metals & Alloys*, Vol. 1, Sept. 1930, page 741. Ha(17)

Forty Years of Seamless Steel Tubes. H. R. SIMONDS. *Steel*, Vol. 87, Dec. 18, 1930, pages 43–46.
Describes plant and methods of the Ellwood Ivins' Steel Tube Works, Oak Lane, Pa. Production is at rate of 250,000 ft. a week. Product varies from 5 in. down to 0.015 in. in diameter, although bulk of output is confined to C steel tubes 1/64–2 in. in diameter. Hollow billets are first pointed and then given a draw or an anneal, depending upon the material and the nature of the draw. Mandrels are held stationary. For extremely small sizes, mandrel is omitted. Drawing operations are repeated until the tube is brought to the desired size. A heavy special drawing lubricant is used. Frequent annealing between draws is necessary. After each anneal, tubes are pickled and washed before drawing. For most steel, annealing temperature is 1400° F. and time is 10–30 min. For drawing Cr-Ni steel tubes, tungsten carbide dies are used, and mandrels made of specially chilled steel having a Brinell hardness of about 650. In this case, mandrels are allowed to follow inside the tube being drawn. To loosen the drawn tube from the mandrel, a tube expander has been developed. It exerts pressure by 3 sets of rolls at 8 different points around the circumference of the tube, resulting in a slight expansion of the tube. Alloy die, high in C with Cr and W, is used for most of the work. All dies and mandrels are Cr plated. MS(17)

Need Careful Heat Treatment in Making Rock Drills. H. R. SIMONDS. *Steel*, Vol. 87, Sept. 11, 1930, pages 48, 50, 54.
Describes practice of the Ingersoll-Rand Co., Phillipsburg, N. J. Drill bits are forged hot in a drill sharpener. Pistons and cylinders for air hammers are normalized, annealed in powdered mica, sand-blasted and ground. They are hardened by preheating in a Pb bath, then holding at a higher temperature in a second Pb bath, and quenching in brine at 75–85° F. They are drawn in an electric furnace and cooled in air. A large number of low-C machine steel parts including those of Bessemer screw-stock are heat treated by the aerocase process of cyaniding. MS(17)

Processing 3-Ton Wrought-Iron Balls—A New Departure. J. D. KNOX. *Steel*, Vol. 87, Nov. 13, 1930, pages 43–46.
Describes new plant of the A. M. Byers Co. at Ambridge, Pa., for the manufacture of wrought-iron by the Aston process. MS(17)

Sheet Maker Installs Modern Furnaces in Expansion. W. G. GUDE. *Steel*, Vol. 87, Sept. 11, 1930, pages 43–46.
Describes equipment of the Apollo Steel Co., Apollo, Pa. MS(17)

MISCELLANEOUS (20)

Examines Foundry Figures Graphically. H. A. SCHWARTZ. *Foundry*, Vol. 58, Aug. 15, 1930, pages 44–47.

Data is translated in % and plotted. The abscissas are accumulated % of heats to and including a given C content shown as the corresponding ordinate. It is likely that a given heat will be found higher or lower than the average and that a given heat differing from the average decreases as the difference from the average increases. Close control is represented by an approach of the lines to the horizontal and the precision of control may be measured by the slope of the line. These charts may be used to check work of chemists. Similar data can be plotted from variations in tool life to determine uniformity of product machined. VSP(20)

Analyzing Failure in Wire Rope with Steel Center. L. E. WYATT (American Cable Co.). *Steel*, Vol. 87, Sept. 4, 1930, page 48.

In cables with independent wire-rope center, overloading of the steel core is not the only, or even the chief cause of failure. Failure may be caused by internal wear. Constant pressure between strands and core causes wear which tends to nick the outer wires of the core. The points of reduced wire section are weaker against bending stress, invite a concentration of flexion, and eventually fail by fatigue. MS(20)

Dimensional Changes in the Manufacture of Electrotypes. N. BEKKEDAHL & W. BLUM. *Bureau of Standards Journal of Research*, Vol. 6, May 1931, pages 829–845.

This investigation was conducted by coöperation between the International Association of Electrotypers and the National Bureau of Standards. Electrotypes made under typical but carefully controlled conditions were measured after each step in the process. The results showed that each operation is likely to produce some change in dimensions. The largest and most variable changes are produced in curving. By controlling all conditions it is possible to produce plates that will register with each other within about 0.05%, though they will usually not have the same dimensions as the originals. (20)

The Development of an Electron Emitting Alloy. O. S. DUFFENDACK, R. A. WOLFE & D. W. RANDOLPH. *American Electrochemical Society, Preprint* 59–17, April 1931 meeting, 17 pages.

It was discovered that irregularities in the sparking voltage of spark gaps were due to non-uniformities in the composition of the electrode materials. Small inclusions of magnesium in the nickel alloy ordinarily employed for spark plug electrodes were found to be distributed at random through the wire and to affect the sparking voltages. A thorough investigation established a complete coördination between the sparking voltage of a gap and the work function of electron extraction from the cathode surface. The sparking voltage of a standardized gap increases when the thermionic electron emission of the electrode wire, measured under standardized conditions, decreases. After many experiments, a nickel alloy containing barium has been developed which is homogeneous in composition and readily reproducible. Spark gaps having electrodes made of this alloy have very constant sparking voltages. The alloy has marked electron-emitting properties that make it valuable for use in various electrical devices. Its uses in several ways are being developed. (20)

Steel Plant Lubrication. W. A. JAMES (Bethlehem Steel Co.). *Yearbook, American Iron & Steel Institute*, 1930, pages 121–147, includes discussion; *Blast Furnace & Steel Plant*, Vol. 18, June 1930, pages 964–967, 1028; condensed in *Iron Trade Review*, Vol. 86, June 12, 1930, pages 61–62; *Rolling Mill Journal*, Vol. 4, May 1930, pages 221–224; *Foundry Trade Journal*, Vol. 43, July 31, 1930, 76 pages.

Paper read before the American Iron & Steel Institute, May 9, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 804. MS+VSP(20)

Metal-Clad Synchronous Motors Latest Thing for Nitrate Plants. *Electrical Engineering*, Vol. 50, May 1931, page 339.

A 250-hp. Westinghouse synchronous motor is under construction for use in an atmosphere of fine nitrate dust. Resistance to the danger of nitric acid damage to its windings is afforded by making the motors metal-clad and supplying a slight static pressure inside to prevent ingress of harmful dust. Inclined fins on the metal enclosure throw off and guide along the most efficient route the cooling air supplied by the fan on the rotor. The motors are designed to operate on 550-volt, 60-cycle circuits and have synchronous speed of 450 r. p. m. A starting torque of 120% and a pull-in torque of 100% are claimed for these motors. WHB(20)

Standard Thicknesses, Weights and Tolerances of Sheet Metal (Customary Practice). *Bureau of Standards Circular* No. 391, Mar. 24, 1931, 32 pages, procurable from Superintendent of Documents, Washington D. C., 10¢ (stamps not accepted).

Compilation of commonly used sheet metal gages, with tolerances as to size, weight and thickness for various gages. It covers iron and steel, galvanized steel, Sn and terne plate, Cu, Al, Pb, Zn, Monel metal, commercial (high) brass, naval brass, gilding metal, cupro nickel, "nickel silver," the aluminum alloys 3 S, 17 S, 25 S and 51 S, with some data on phosphor bronze, wrought aluminum bronze, wrought manganese bronze, low and rich low brass. British, French, German and Japanese gages are also tabulated. HWG(20)

What Is the Economic Weight of Rail? *Railway Age*, Vol. 88, May 24, 1930, pages 1231–1237.

An exhaustive study of the Kansas City Southern covering a period of 2 years has resulted in the substitution of a 137-lb. rail section for the 85-lb. section. The comparative physical properties of various rails is given in the following table:

Rail Section	Weight/Yd.	Tons/Mile	Moment of Inertia	Comparative Stiffness	Mean Carbon Content
85	85	133.6	34.0	100	0.70
100	101.5	159.5	49.0	144	0.75
115	114.4	179.8	64.0	188	0.75
127	127.3	200.0	83.7	246	0.81
150	150.5	236.5	121.1	356	0.85

All factors such as stresses under dynamic loading, service life, effect of rolling and rate of cooling for the different rails, volume of traffic, cost, maintenance, train resistance, etc., were considered and the following summary table prepared:

Summary Net Economic Value of the Different Rail Sections per Track Mile

Rail Section	Savings in Track Labor per million gross ton mi. of traffic	Savings in Track Renewals	Savings in Maintenance of Equipment	Savings in Train Operation	Total of Savings	Cost of Rails Place	Net Economic Cost	New Saving
85	$00	$00	$00	$00	$ 00	$190	$190	$ 00
100	46	4	14	8	72	198	126	64
115	64	8	26	14	112	197	85	105
127	71	10	34	18	133	200	67	123
150	84	13	44	21	162	230	68	122

VVK(20)

Movements in Metallurgy and Heat Treatment. GEORGE B. WATERHOUSE. *Iron Age*, Vol. 127, Jan. 1, 1931, pages 42–43.

In blast furnace practice, large hearth furnace installations were made; also better methods of gas cleaning were applied. Large number of automatic control devices for open-hearth furnaces were made. Installations of high frequency induction furnaces up to 3½ to 4 tons capacity. High Cr, 18 and 8, and similar steels were made by a cheaper process. Advance in heat treatment has been most marked in regard to furnace design and temperature control. Electricity, gas and oil used for heating with good results. VSP(20)

66-Ft Rails Prove Successful on the Lehigh Valley. *Railway Age*, Vol. 88, May 17, 1930, page 1173.

The Lehigh Valley relaid a total of 1000 tons or about 5 consecutive track miles of 33 ft. rails near Towanda, Pa., with 66 ft. rails of 136 lb. LV section. This had been suggested by the fact that the 33 ft. rails laid tight with no possibility of expansion, has given no trouble and also by the German State Railways practice of using 30 meter or 98.42 ft. lengths. No trouble was encountered from an expansion standpoint with these 66 ft. rails. VVK(20)

On the Cooling of Bodies with Internal Heat Sources. (Ueber die Abkühlung von Körpern mit inneren Wärmequellen.) H. SCHMIDT & W. UHINK. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 20, 1930, Report 165, pages 323–342; *Stahl und Eisen*, Vol. 51, Feb. 5, 1931, pages 176–177.

The article gives the practical results and the mathematical evaluation experiments on the cooling of bodies in which heat is generated during the cooling process (for instance, change of crystal form in iron alloys). GN(20)

Ford Production Methods. T. GORST. *Automobile Engineer*, Vol. 20, Nov. 1930, pages 442–444.

Abstract of a paper presented to the Institution of Production Engineers. Deals very briefly with metals used and their treatment. Considers largely handling and assembly methods, size of plants, payment of employees and a trade school for boys. RHP(20)

The Lateral Bending of Bars, Limited by Surfaces of Second Order. A. N. DINNIK & A. S. LOKSHIN. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Nov. 1930, pages 785–808.

Deals largely with the mathematical theory of forces required in bending lateral bars of varying cross-section. Considers the elliptical cylinder, elliptical cone, triaxial ellipsoid, hyperboloid of one and of two sheets, and the elliptical paraboloid. RHP(20)

The Removal of Beer-Stone from Brewery Apparatus of Aluminum. (Zur Frage der Entfernung des Biersteins aus Aluminium-Brauereigefässen.) G. ECKERT. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Nov. 1930, pages 194–196.

After a short storage time, a precipitation or deposit, beer-stone, is formed on the walls of the tanks which must be removed from time to time to prevent an impairment in the quality of the beer. Several means for the removal have been tested. Nitrous gases were found to be the most effective. The method of their application is described. Ha(20)

LABORATORY APPARATUS (21)

An Automatic Apparatus for Making Corrosion Determinations. G. KUERNER. *Chemist-Analyst*, Vol. 19, May 1930, page 18.

The corrosive liquid is heated in a beaker and percolated through a glass onto the sample supported in a glass tube above the beaker. A reflux condenser attached to the tube returns the liquid to the beaker and the action is continuous. The apparatus can be assembled from materials carried in any laboratory. CEM(21)

An Oxy-Aluminum Blowtorch. R. A. BAKER & F. M. STRONG. *Industrial & Engineering Chemistry*, Vol. 22, July 1930, pages 788–789.

A blowtorch utilizing finely powdered Al as fuel is described. The combustion products show less than 2% unburnt Al. Molybdenum melts in this flame, tungsten (1 mm.) does not. The Mo melt, when analyzed, showed no Al. MEH(21)

Laboratory Feeder for Flotation Reagents. *Engineering & Mining Journal*, Vol. 131, Mar. 23, 1931, page 277.

An illustrated description of an apparatus affording close regulation of minute quantities on a laboratory scale. Addition of oil is made by an eccentric revolving disc dipping into a storage tank. The amounts of reagents fed may be regulated by changing the volume of the cups and the number of cups used on each disc and by varying the tipping angle when discharging the contents of the cups. WHB(21)

Laboratory Tester of Lubricants Available for the Shops. *Electric Railway Journal*, Vol. 75, Mar. 1931, page 154.

The Timken Roller Bearing Co. has just put out a testing apparatus to determine the quality and efficiency of lubricant and bearing metals under various conditions of load. The apparatus consists of a cast iron base which supports the testing mandrels, two levers and a container holding a gallon of the lubricant on test. The tank is mounted above an electric heater which can heat the oil to the temperature of 210° F. The oil flows over the test piece to a sump and its rate of flow is adjusted by a valve in the line. From the sump the oil is pumped back to the tank in the base driven from the testing mandrel. Driven by a variable-speed motor the mandrel is rigidly held in alignment by two Timken bearings and is tapered at the test end to receive the tapered cup of a bearing. This cup forms one of the test pieces and is held in place firmly by a nut on the threaded end of the mandrel. Two levers, one above the other, form the heart of the apparatus—the upper is the load lever and the lower the friction lever. The upper lever carries the test block and is pivoted on a knife edge in the lower lever, which is also pivoted on a knife edge and has a stop at the unloaded end. The test block is parallel to the revolving cup, and the unit loading over the length of both pieces is constant. A small piece of metal ½ × ½ × ¾ in. hardened to Rockwell C-60 and ground, forms the test block. It is inserted in a notch in the load lever and is held in place by a wedge. For testing bearing metal, both the test block and the cup can be made of appropriate material. The friction lever has a vernier scale and a sliding weight scale for accurate measurements. Both levers are equipped with hangers for adjustable weights. The operation is outlined. A chart is furnished with the apparatus to indicate the necessary weights per 1000 lbs. pressure. WHB(21)

FOUNDRY PRACTICE & APPLIANCES (22)

Sand Control Increases Economy in the Foundry. O. E. J. ABRAHAMSON. *Foundry*, Vol. 58, Mar. 15, 1930, pages 84–87; April 15, 1930, pages 74–78; May 15, 1930, pages 56–60; June 15, 1930, pages 56–59.

Describes the results of study of the various components of molding sand by analysis and synthesis. Gives curves showing the relationship between % of bond, size of sand grain and the permeability determined according to the American Foundrymens' Association method. Further tests conducted with synthetic sands containing lake sand of 94.83% SiO_2, 2.78% Fe, and Al oxides, 1.02% lime and 0.96% magnesia. Tabulates results. By the use of the permeability device, the hardness tester and electrical moisture testing device, molding sands are quickly tested for openness, permeability, bond and moisture. Sand may show a high dry bond strength, considerable trouble may arise from its use in the form of dirt, washes, scabs, drops, etc., since the true bond may be low. Addition of fine grades of sand to coarser grade reduces the permeability of the mixture. The maximum permeability of a sand is higher than the average permeability in almost direct proportion to % of bond present. The study of molding sands has resulted in establishment of laws and rules making it possible to take any number of sands and by simple calculations to predict the properties that any mixture of these sands will have. Author describes his own laboratory tests of sand control in foundries. VSP(22)

Melting Furnaces for Use in the Bronze Foundry. ERNEST R. DARBY (Federal-Mogul Corp.). *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1247–1250.

Defective bronze castings may often be due to improper melting or to a furnace not suited to the material it is to melt. A furnace with a fixed neutral atmosphere is the most suitable for castings made of virgin metals. An excellent example is the induction electric furnace. The coke-fired pit furnace with its reducing atmosphere, and the oil- and gas-fired crucible furnaces, with their adjustable atmospheres, are applicable to melting this class of material. The latter are also suitable for melting other classes. The large capacity oil- or gas-fired reverberatory furnace is not well suited for melting virgin metal compositions, unless there is sufficient tonnage of one class of alloy to permit of keeping a furnace specially for it. Secondary bronzes with much more than 5% Zn are satisfactorily melted in any of the crucible or electric furnaces, the arc furnace being exceptionally good. The open-flame reverberatory and cupola type furnaces are of most service for low Zn bronzes. MS(22)

Select Brass Scrap with Care. J. W. ARTHUR. *Foundry*, Vol. 58, Sept. 15, 1930, pages 72–73.

The composition of the scrap decides the amount to be used. When fine castings are desired sheet scrap should be used, but the composition must be known. When salt has been used as flux the resulting sheet when made up into manufactured goods is liable to failure. In melting, Cu should be charged first, then the scrap and the Zn last of all. VSP(22)

Lamp Post Design Determines Molding Methods. NORMAN F. HINDLE. *Foundry*, Vol. 58, Dec. 1, 1930, pages 82–84.

Describes method used by the Westinghouse Electric & Manufacturing Co. Two methods are used in the manufacture of gray iron lamp posts. Those which are fluted are rammed by hand while those with shallow or no flutes are made on a jolt, roll-over, pattern draw molding machine. Iron used in the posts is a 10% steel mixture. Pouring temperature depends upon the size of the casting. VSP(22)

Steel Foundrymen Should Study Pattern Costs. WILLIAM DONNELLY. *Foundry*, Vol. 58, Aug. 15, 1930, pages 56–57.

Abstract of paper presented before the Small Castings Division of the Steel Founders' Society of America at Chicago. VSP(22)

Sound Malleable Iron Castings Depend on Feeding Methods. EDWIN BREMER. *Foundry*, Vol. 58, Oct. 1, 1930, pages 76–80.

Describes method employed in producing castings at the Maumee Malleable Castings Co., Toledo, Ohio. VSP(22)

Southern Foundry Concentrates on Special Pipe Shapes. PAT DWYER. *Foundry*, Vol. 58, Oct. 15, 1930, pages 54–58.

Describes method used by the Bessemer Foundry & Machine Co., Bessemer, Ala., in the production of miscellaneous castings of odd and intricate shapes. VSP(22)

Pressure Die-Cast Aluminium Alloy Test-Pieces. J. D. GROGAN. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 279–304.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 855. (22)

Die Casting or Mold Casting. (Spritzguss oder Kokillenguss.) A. KAUFMANN. *AEG-Mitteilungen*, Vol. 4, Mar. 1931, pages 176–180.

The decision whether a metal piece is to be cast in a mold or in a die must be made by the designer, since the shape must utilize the respective advantages of the methods. For a very exact casting, the die gives best results. A table shows the limitations for die casting both for low melting heavy alloys and for high melting light alloys. For certain requirements with respect to mechanical properties, mold casting is preferable since the velocity of cooling influences these properties very materially. Ha(22)

Synthetic Molding Sand Requires a Proper Base. L. B. KNIGHT (Illinois Clay Products Co.). *Foundry*, Vol. 58, Dec. 1, 1930, pages 80–81.

Abstract of a paper read before the Wisconsin Gray Iron Foundry group. Chemical analyses of good fire clay vary from 50 to 65% silica; 30 to 42% alumina; and 3 to 4% bond. Few clays contain more than 4% Fe. Moisture loss on ignition varies from 8 to 16%. Fusion point of good plastic fire clay is about 3000° F. It is not difficult to manufacture a synthetic molding sand. Moisture content is one important item to be considered in use of synthetic sand. Proper moisture is between 4½ to 5½%. VSP(22)

Strong Aluminum Castings Are Obtained by Improved Foundry Practice. T. D. STAY, E. M. GINGERICH & H. J. ROWE. *Foundry*, Vol. 58, Dec. 1, 1930, pages 72–75, 103.

From a paper presented at the annual meeting of the American Foundrymens' Association in Cleveland, May 12–16, 1930. Methods of molding castings from same pattern may vary, and no two castings will show same properties. Since castings must withstand certain stresses, probably only one of the methods of molding will fulfill requirements. VSP(22)

Light Alloy Pistons Are Cast in Permanent Molds. EDMUND R. THEWS. *Foundry*, Vol. 58, Nov. 15, 1930, pages 67–69.

Light piston alloys should possess sufficient strength to withstand the shocks and gas pressures imposed at temperature varying from 200° to 400° C. Thermal absorption capacity and conductivity must be high. Addition of Ni and Mg appears to lower the specific weight. Gives a list of some satisfactory light piston alloys produced in America, England, Germany and France. Another table gives the physical and mechanical properties of some European alloys. All piston alloys contain from 3 to 15% Cu. A series of new Al alloys containing in addition to Cu, varying amounts of the Fe group. These alloys have a low coefficient of expansion. Thermal conductivity of light Al alloys is high. Chief advantages of higher thermal conductivity Al alloys claimed are: Increase in power, fuel economy and elimination of carbonization of oil under piston head. Permanent molds are used for casting all but the complicated types of pistons. Sal-ammoniac coagulates drosses; it is added to the melt just before casting. Alloys are usually melted in graphite crucibles. VSP(22)

MOORE RAPID 'LECTROMELT FURNACES

Lectromelt

A 500 lb. per hour 'LECTROMELT furnace installation being used for special alloy work.

'LECTROMELT furnaces offer the rapid and economic means of producing stronger, denser, cleaner and closer grained irons and steels under constant analytical and temperature control.

Over 40 users making corrosion and heat resistant irons and steels.

Cupola Pitfalls and Ways to Avoid Them. ROBERT W. WATSON (Semet-Solvay Co.). *Foundry*, Vol. 58, Dec. 1, 1930, pages 85–86.
From a paper read before the American Foundrymens' Association. Long life of lining is essential for economic success. Successful melting depends on the lighting, burning of the bed, measurement of air, pressure of air and accurate weights and measures. Many important variables have a direct bearing on the successful operation of the cupola in the foundry. VSP(22)

Cast Pipe with Universal Joints. PAT DWYER. *Foundry*, Vol. 58, Nov. 15, 1930, pages 42–46.
Describes method employed by the Central Foundry Co., Bessemer, Ala. VSP(22)

The Preparation and Laboratory Control of Foundry Sands. J. D. BURLIE. *Journal Western Society of Engineers*, Vol. 36, Apr. 1931, pages 80–89.
A paper which won the Charles Ellet Award of the Junior Engineers in 1930. An outline is given of the general characteristics, source, preparation, requirements and methods of control of foundry sands. Sands have two main classifications: those containing little or no natural binding material and those containing it. The first group is used essentially in the production of synthetic molding sands and cores and the latter as a molding sand. Sand testing and control equipment are discussed and many data tabulated. Conclusions drawn are: Introduction of controlled properties of molding sand has contributed to the realization of a more positive control of casting technique. By the use of suitable sands, the scrap losses may be reduced and result in an improved quality of castings. Accurately controlled sand properties bear a close relation to an increased rate of production. WHB(22)

Pressure Pipe is Cast Horizontally. PAT DWYER. Part I. *Foundry*, Vol. 58, Sept. 15, 1930, pages 48–51, 74; Part II. Oct. 1, 1930, pages 99–102.
Describes process of casting patented by J. R. McWane and used by the McWane Cast Iron Pipe Co. Pipes 16 ft. and up, 12 in. in diameter are cast in green sand molds and cores. Part II. Gives details of core making, shaking out and cleaning of long pressure pipe cast in green sand molds. VSP(22)

Continuous Oven Reduces Core Losses. J. B. NEALEY. *Foundry*, Vol. 58, Aug. 15, 1930, pages 58–60.
Describes a counter flow, heat sealed, indirect heated, gas fired, two compartment, continuous type, core oven to bake crankcase cores installed by the Studebaker Corp., South Bend, Ind. VSP(22)

New Foundry Casts Alloy Steels. EDWIN BREMER. *Foundry*, Vol. 58, Sept. 15, 1930, pages 61–63; Extended abstract, *Steel*, Vol. 87, Sept. 25, 1930, pages 54–55.
Describes new plant of Ohio Steel Foundry Co., Springfield, Ohio, in which only alloy steel castings are produced. The alloy steel castings consist of steels containing varying amounts of Cr and Ni. One of the alloys contains 35% Ni and 15% Cr and is used for heat resisting to withstand temperatures up to 2000° F. Another alloy contains 18% Cr and 8% Ni and will resist up to 1700° F. The third alloy contains 20% Cr and 2% Ni and will resist atmospheres containing sulphurous vapors. VSP(22)

Manganese Steel Manufacture Involves Care in Melting. G. P. MESSENGER (Kensington Steel Co.). *Steel*, Vol. 87, Sept. 25, 1930, pages 47–48, 50, 52.
Describes manufacture of Hadfield Mn steel. Outlines various processes of steel making. Mn steel is usually made by the cold scrap process in the basic electric furnace. Scrap must have a very low P content. During melting down, slag should be heavy in CaO and yet be fluid. When the bath is melted, a deoxidizing slag composed of 6 parts CaO, 1–2 parts powdered coke and 1 part fluor-spar is used. Bath should be exceedingly hot before the heat is tapped. Cores should be removed as soon as the steel is solidified and strong enough to withstand handling. Castings with uneven sections are charged immediately into a hot furnace and allowed to remain until the heat has been distributed uniformly through the mass. Shrinks or checks are usually eliminated by welding. In annealing, rate of heating should be comparatively slow especially during the latter part of the heating operation, and the casting should be protected from oxidation. The castings are cooled by dumping into H_2O as cold as it is possible to obtain. MS(22)

Preventing Unsoundness in Bronzes and Red Brass. *Foundry*, Vol. 58, Sept. 1, 1930, pages 108–111; Oct. 15, 1930, pages 75–78; Nov. 15, 1930, pages 47–50, 54; Dec. 15, 1930, pages 48–51, 76.
Of the 3 conditions of atmosphere, the most difficult to obtain is the neutral one. Most bronzes absorb gas formed by incomplete combustion. The amount of solution increases rapidly with increase in temperature, the duration of overheating and increase in explosion pressure of incoming fuel. Most harmful effect of gas is due to its precipitation at or near the temperature of solidification. With reducing atmosphere there is a danger of gas absorption during the first period. In melting in oxidizing atmosphere, the most serious difficulty is the formation of oxides. The solubility of hydrogen and carbon monoxide and sulphur dioxide is reduced by alloying with tin and zinc. It is reduced still further by the presence of oxygen in metal. The critical period during the production of sound bronze and red brass castings is the solidification period. During freezing, bronze contracts considerably. Cooling rate depends on pouring temperature of alloy, relation of volume to surface area, the use of chills and like factors. In addition to unsoundness caused by gas, certain elements in bronzes and red brass have a considerable effect upon the properties of the alloys. Elements having a deleterious effect include Al, Sb, As, Bi and Fe. Ni appears to have a beneficial effect, while Si causes incipient shrinkage. Gives data obtained from various investigators under same melting conditions. S forms sulphides and inclusions in the metal. By using soda ash fluxes, S may be reduced. Much of the difficulty encountered from porosity in non-ferrous alloys may be due to the type of atmosphere maintained in the furnace. Woyski and Boeck conclude that gas and shrinkage cause porous metal and intercrystalline fissures. Metal subjected to bad melting practice may be brought back to normal by proper furnace practice. According to Bolton and Weigand in advancing the incipient shrinkage theory, the observations of Woyski and Boeck and the indicative effects of atmospheric conditions in open flame gas, crucible and indirect arc electric furnaces are confirmed. Inclusions appear as patches. Blow-holes are caused directly by the evolution of dissolved gas during solidification and, in case of Cu or its alloys, this gas is considered to be O. Best casting temperature for admiralty bronze is about 2192° F. Analysis of gas obtained by heating pure Cu resembles gas from Cu-Zn alloy and this suggests the gases causing unsoundness in alloys are actually in Cu itself. Bad influence of gas can be eliminated wholly or in part by thermo-mechanical treatment. Most of the work on unsoundness of bronze and red brass has resulted in modifying the effects rather than ascertaining the causes. In his recent work Daniels has attempted to solve the problem in 2 ways: (1) by applying existing knowledge to melting and casting of the alloy and (2) by examining the effect of various gases on small quantities of the alloy melted in small C or clay boats. N and CO_2 are neutral toward bronze. H is capable of causing unsoundness in bronze at certain rate of solidification. Improvement in density of sand casting can be obtained by melting in a pot-furnace with a thin fuel bed and good draught. Liquid shrinkage must be compensated by proper feeding. The object of gating is to fill mold perfectly and to supply fluid liquid metal to feed the casting and compensate for liquid shrinkage. Cope shrinkage usually is a consequence of cold metal and poverty of pressure. Effects of incipient shrinkage usually occur in section of casting last to solidify and between primary dendrites. Good raw materials are essential. Impurities to be avoided are: Si, Sb, As, S, etc. VSP(22)

DETROIT Rocking Electric FURNACES

Small (250 lb.) Detroit Electric Furnace Pouring Heat of Alloy Steel

These furnaces manufactured in capacities from 250 lbs. per hour to 6000 lbs. per hour, offer unusual economy in the production of grey iron, malleable iron, alloy steel, or non-ferrous castings showing the highest possible quality. The rocking action of the

DETROIT ELECTRIC FURNACE

insures complete homogeneity and uniformity, as well as physical characteristics of a highly superior character in the finished castings. Over 50 DETROIT ELECTRIC FURNACES are in use in melting or duplexing grey iron or alloy steel, and over 400 furnaces are in use in the non-ferrous foundries throughout the world.

We will be pleased to send you complete information regarding these remarkable furnaces.

FURNACES & FUELS (23)

Open Hearth Control. MARTIN J. CONWAY (Lukens Steel Co.). *Iron & Steel Engineer*, Vol. 8, Jan. 1931, page 29; June 1931, pages 289–298.
The author gives and discusses data compiled on a number of open-hearth furnaces. Discusses the various advances made since about 1922 in control of fuel-air ratio, checker temperature control, stack draft control. Fuels are discussed with the energy requirements of the open hearth. Waste gas movement and savings available by the application of proper control are discussed.

Coke-Oven Gases as Basis for Chemical Raw Materials. (Die Koksofengase als chemische Rohstoffbasis.) HORTS BRUECKNER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Jan. 24, 1931, pages 93–97.
The chemical utilization of coke-oven gases by the individual constituents, hydrogen, ethylene, carbon monoxide and methane must be carried out from the national economical viewpoint. Hydrogen is now utilized for synthetic ammonia in several plants and the quantities of methane produced by it can be converted into benzol hydrocarbons and chlorated dissolving agents; carbon monoxide and hydrogen can be converted into methanol and benzene hydrocarbons; ethylene is convertible into dissolving agents and ethyl alcohol. Processes for such conversions have been developed and promise to be commercially profitable if carried out on a large scale, if the price of coke oven gas does not exceed RM 0.015 to 0.017. These processes are discussed and practical figures are given. 14 references. Ha(23)

Continuous Reheating Furnaces for Rolling Mills. A. L. CULBERTSON. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, 1930; *Iron & Steel*, pages 61–72.
Includes discussion. Paper is confined to those furnaces used for reheating purposes, necessary for serving, rolling and piercing mills. Even this reduced field leaves it an extremely broad one when considering the types of furnaces required for the different operations. (23)

The Practical Side of Metallurgical Heat Application. H. DOBRIN. *Iron & Steel Engineer*, Vol. 8, June 1931, pages 256–264.
The author shows the great difference in the heating efficiencies obtained in boilers and metallurgical furnaces, 80% in the former against only about 20% in the latter. He points out that the boiler people have cut their stack gas temperature to 600° F. while metallurgical furnaces give off gas at 1600–1700° F. Metallurgical heating is hampered in obtaining maximum fuel efficiency on account of desire for quality in the product and by personnel. Failure to appreciate the advantages to be obtained and proper use of the equipment and methods available have resulted in inefficiency. Improvements that are being made particularly in the open-hearth and soaking pit furnaces toward control of the fuel-air ratio are pointed out. WLC(23)

High Frequency Electric Steel Furnaces. (Les fours à acier à haute frequence.) D. F. CAMPBELL. *Journal du Four Electrique*, Vol. 40, Apr. 1931, pages 125–134.
A paper presented at Sept. 1930 meeting of the Iron & Steel Institute in Czechoslovakia and printed, with discussion, in the *Journal of the Iron & Steel Institute*. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 16. JDG(23)

The Practical Side of Metallurgical Heat Application. H. DOBRIN. *Iron & Steel Engineer*, Vol. 8, June 1931, pages 256–264.
A paper pointing out the necessity of application to the details of control. Soaking pits are becoming standard equipment. For all proper metallurgical heating, the furnace pressure must be positive. Through the various heating processes, required to manufacture, say a seamless tube, quite a variety of furnaces are employed. Any one of these in a chain may undo the good of all the rest. Burners must be kept clean and other equipment must be inspected and cleaned. W.H.B.(23)

Germans Study Induction Furnaces. Correspondence from E. W. EHN, Cannstatt, Germany. *Metal Progress*, Vol. 19, Jan. 1931, pages 86–87.
Germans are giving this type of furnace considerable attention and are developing its metallurgical uses rapidly. WLC(23)

Electric Heating Insures Quality Production. H. J. FISCHBECK. *Electrical World*, Vol. 97, Apr. 11, 1931, pages 680–681.
Electric heat employed by the Pratt & Whitney Aircraft Corp. as a result of the following advantages: (1) high efficiency, with attendant quality of work, (2) simplicity of application, (3) close automatic temperature control, (4) cleanliness and improvement of working conditions, (5) impossibility of over heating any part of the charge, and (6) elimination of the combustion method with its attendant uncertainty of results and general fuel problems, plus reduced fire hazards. Carburizing, hardening and miscellaneous heat treating are handled. WHB(23)

Large Output of Steel from Cold Charge. Correspondence from F. GIOLITTI, Turin, Italy. *Metal Progress*, Vol. 19, Mar. 1931, pages 86–87.
The writer describes a new design of open-hearth furnace for greater fuel economy in production of steel from cold charge. WLC(23)

Hot-Blast Stove Heating and Its Equipment. HERMANN ILLIES. *Iron Age*, Vol. 126, Dec. 4, 1930, page 1699.
Describes the Askania high efficiency burner made by Zimmermann & Tansen, G.m.b.H., Düren Germany. This burner takes care of insufficient stack draft in supplying the necessary quantity of gas and air, and provides good combustion. For small capacities, burner can be fitted with injectors. VSP(23)

Large Industrial Furnaces with Gas Firing and Their Burners. (Gross-Industrieöfen mit Gasfeuerung und deren Brenner.) JOH. JEHNIGEN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 9, 1931, pages 577–583.
Low-pressure and high-pressure gas burners are described briefly and illustrated. The following types of furnaces are described and several constructions are illustrated: a small pusher furnace for heating steel bars, 5 t./hr., consumption about 500,000 to 540,000 kcal./t. of material; a large pusher furnace, for 45 t./hr., 385,000 to 425,000 kcal./t.; continuous and annealing furnaces, gas consumption 260,000 to 490,000 kcal./t. of wire; a furnace with moving hearth and moving material, for high grade sheets for deep drawing, about 550,000 to 600,000 kcal./t. are consumed. Ha(23)

Nitriding Furnaces and Equipment. W. J. MERTEN. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 502–522.
Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The author describes nitriding equipment used for continuous nitriding employing a movable bell electrical heater. The efficiencies of the equipment are given and discussed. The results are uniform and economically obtained. WLC(23)

Electric Heat-Treating Furnaces. A. H. VAUGHAN (Electric Furnace Co.). *Iron Age*, Vol. 125, Jan. 30, 1930, pages 357–361.
From an address before the Cleveland chapter of the American Society for Steel Treating. Describes the various types of electric furnaces. The advantages of the continuous electric furnace over other types is that every zone does the same part of the heating and can always operate close to 100% of capacity. For annealing work the counterflow recuperative type of furnace gives good results. Power consumption is about half that of a non-recuperative unit of the same size. Conveyor furnaces are difficult to construct. For heat treatment of Al alloys only electric heat is used. Largest furnace built is a 3000 kw. car type. VSP(23)

Car Bottom Furnace Used in Jobbing Heat Treating Plant. *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1237–1238.
Wesley Steel Treating Co., Milwaukee, has added a gas-fired, single-end, car-bottom furnace for miscellaneous heat treating, annealing, hardening and carburizing. It is 13 ft. long, 6½ ft. wide and 5½ ft. from car top to spring line of arch. There are 11 two-stage velocity type burners on each side, so staggered as to provide both over and under firing. MS(23)

Heat Treatment Furnaces Used in the Manufacture of Telephone Equipment. W. A. TIMM. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1395–1398, 1417.

Electric Annealing of Aluminum. *Metal Industry*, London, Vol. 38, Apr. 3, 1931, page 364.
Description of a new single track multi-car type electric annealing furnace, rating 150 kw. at 440 volts with nickel-chromium heating elements on side walls, roof and each section of car. Running contacts below the car are used. The furnace is 24 ft. × 7 ft. 5 in. and is used for annealing Al sheet. PRK(23)

Brass Melting Furnaces Are Fired with Two Oil Burners. CHARLES VICKERS. *Foundry*, Vol. 58, Nov. 1, 1930, page 92.
Describes an oil-fired rotary, non-crucible furnace for melting Ni-Ag alloys, bronze, brass and Al. Furnace was devised by Tasman Storey, Storey Bros., Ltd., Sydney, New South Wales. VSP(23)

Open-Hearth Furnace Developments in 1930. *Iron Age*, Vol. 127, Jan. 1, 1931, page 35.
Attention to combustion of fuels and automatic control of furnace operations has marked the progress in open-hearth practice the past year. No startling developments made during the year, merely a progression along lines already well explored. VSP(23)

Electric Furnaces for Melting Aluminium. *Metal Industry*, London, Vol. 38, Apr. 3, 1931, pages 357–360.
Translated by I. Boodson from "Das Electrische Schmelzen von Aluminium" by Russ in *Zeitschrift für Metallkunde*. There are given descriptions of electric crucible furnaces of 50–350 kilos capacity, tank furnaces with refractory brickwork for unwieldy charges and hearth furnaces for large charges and high output. PRK(23)

Experiments on the Heat Transfer in Rolling Mill Furnaces with Special Reference to the Soaking of the Ingots. (Versuche über den Wärmeübergang in Walzwerksöfen unter Berücksichtigung der Durchwärmung der Blöcke.) A. SCHACK. *Archiv für Eisenhüttenwesen*, Vol. 4, Jan. 1931, pages 333–342; *Stahl und Eisen*, Vol. 51, Feb. 5, 1931, pages 162–164.
Report 146 of the Heat Committee of the Verein deutscher Eisenhüttenleute. The heat transfer in industrial furnaces was studied, particularly in rolling mill furnaces. The results of the measurements and the practical conclusions are discussed. Considerable temperature differences were found between the top surface and the bottom surface of the heated material. Temperature differences of 200° C. were observed even in small billets of 90 mm. in the middle of the furnace. In 210 mm. billets, differences up to 300° C. were found. The practical conclusions are as follows: the temperature difference between top and bottom surface of thick material can be made equal to that of thin material when the heat transfer/unit time on the thick material is decreased proportionally to the thickness and by simultaneously increasing the heating time proportionally to the second power of the thickness of the material. This condition cannot be entirely fulfilled in heating furnaces. The heat transfer through direct radiation of the heating gases amounts to about 50% of the total transfer, 30% of the heat is transferred through radiation of the furnace roof, and a relatively small amount through convection. For the total heat transfer through radiation of gases and the roof and through convection, the following equation was found: α (total) = $50 + 0.45(t - 700)$ kg.cal./m.² hr.° C. GN(23)

The Theory of Coreless Induction Furnaces. (Zur Theorie der kernlosen Induktionsöfen.) W. ESMARCH. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 172–196.
A theory of coreless induction furnaces is developed under consideration of the finite length of coil and charge. All characteristic quantities can be calculated by means of 2 functions, A and Q, for which curves and tables are computed. The quantities calculated by the theory are about 2% exact. The efficiency of a high frequency furnace is independent of the frequency and depends only on the geometrical conditions of the furnace and the specific constants of the material (specific resistance and permeability) as long as the condition (always fulfilled in melting furnaces) holds good that the ohmic resistance of the charge is small against the inductive reactance of the latter. If this condition is not fulfilled, the efficiency decreases with decreasing frequency. The energy consumed by the charge can be represented over the whole range of $d = 4\,\delta$ by

$$W_2 = 6.1 \times 10^{-10}\, QA\sqrt{\sigma\mu\nu}\, z^2 \text{ KW}$$

with an error not over 3%; in this case, z = number of ampere turns, d = diameter of charge, δ = penetration depth of the current. A formula is developed for the motive forces which determine the motions in the bath and the crown of the level of the bath, and another formula which permits the calculation, for a given frequency, of the smallest diameter of the furnace for economical operation. The theory was confirmed by a series of experiments. Ha(23)

Use of Fuel Oil in Steel Making Offers a Path to Increased Economies. MARTIN J. CONWAY (Lukens Steel Co.). *Iron Age*, Vol. 126, Aug. 21, 1930, pages 486–487, 517.
Calorific efficiency of open-hearth furnaces has not improved. For every 100 lbs. of fuel burned, only about 30 lbs. are utilized in actual manufacture of steel. Production of steel with lowest expenditure of fuel depends on: (1) Quality of fuel; (2) Furnace output; and (3) Efficient utilization. For commercial heat production the combustible elements must have an affinity for O_2. Fuel oil is especially rich in combustible elements. Advantages of fuel oil are: it does not lose its fuel value in storage; it burns with a high flame temperature, but it is not hard on refractories; checker remains clean longer; and stack capacity is reduced 35%, when compared with producer gas. Oil should be properly atomized. Each checker chamber should be uniformly heated. Gives a list of 33 usual causes of waste. VSP(23)

Wire Patenting Furnace Proves Very Economical in Operation. R. E. BARKER. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1409–1410.
Describes gas-fired furnace, constructed on recuperative setting, which gives very satisfactory operation on all sizes of rod or wire being run at varying speeds, with positive control of atmosphere and economy in fuel. MS(23)

Continuous Reheating Furnaces for Rolling Mills. A. L. CULBERTSON (Rust Engineering Co.). *Rolling Mill Journal*, Vol. 4, Oct. 1930, pages 527–530, 555–556.
From paper read before the American Society of Mechanical Engineers, Sept. 22–24, 1930. MS(23)

Application of Metallic Recuperators to Industrial Furnaces. G. D. MANTLE (Surface Combustion Co.). *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1389–1390.
Abstract of paper read before the Iron and Steel Division of the American Society of Mechanical Engineers. MS(23)

REFRACTORIES & FURNACE MATERIALS (24)

Refractory-maintenance Cements in the Nonferrous Foundry. H. E. WHITE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Nov. 1930, pages 654–672.

Forty-nine brands of cements were studied. Data secured in 1926 and 1929 are compared and show that the use of the so-called super-refractories are on the increase. CHL(24)

The Possibility of Andalusite as a Refractory. FRANK H. RIDDLE. *American Electrochemical Society, Preprint* 59-24, April 1931 meeting, 16 pages.

Important developments in the composition and method of manufacture of refractories have taken place during the last ten years. Length of service is today the preliminary consideration in the selection of a refractory. The commercial development of $Al_2O_3 \cdot SiO_2$ refractories is briefly outlined. The outstanding results stimulated the search for extensive deposits of a natural mineral of this so-called "sillimanite type." Regardless of the proportions in which the two oxides Al_2O_3 and SiO_2 occur to begin with, after exposure to furnace temperatures mullite, $3Al_2O_3 \cdot SiO_2$ is formed with one or the other oxide in excess. Many experiments have shown that andalusite of proper grain size and proportion, when held together with a minimum amount of a plastic aluminous bond such as clay, makes a very desirable active refractory. It is constant in volume during the calcining. An extensive deposit of andalusite has been located in Mono County, California. About 350 million spark plug cores have been made from this andalusite. Important localities of cyanite, sillimanite and dumortierite are briefly described. Tests on andalusite refractory are detailed, demonstrating its superiority over other refractories of this class. (24)

Refractory Materials for Electric Furnaces. II—Copper and Its Alloys, Including Bronze, Gun-metal, Brass, Copper-Nickel and Phosphor-Bronze. ALFRED B. SEARLE. *Metal Industry*, London, Vol. 38, Mar. 27, 1931, pages 333–335.

Magnesite brick linings should be used in furnaces for smelting, refining or melting Cu and its alloys if Pb is present. The use of silica, fireclay, fused magnesia, magnesia spinel, Kieselguhr, carborundum and zirconia is discussed along with fritted linings which give satisfactory service with high copper brasses. PRK + WHB(24)

Refractories. Report of A. S. T. M. Committee C8. G. A. BOLE, Chairman. *Preprint No. 50 for June, 1931 Meeting American Society for Testing Materials.* 10 pages.

Slight changes are proposed in some specifications and methods of test sub-committees are developing abrasion tests for high and room temperatures, methods of making the pyrometric cone equivalent test, types of furnaces for high temperature load tests, and petrographic methods for study of slag attack upon refractories. The development of methods for measuring heat transmission is also mentioned. HWG(24)

Refractory Materials for the Induction Furnace. J. H. CHESTERS & W. J. REES (Sheffield University). *Iron & Steel Institute, Advance Copy* No. 4, 1931, 16 pages.

Crucibles can be used in the coreless induction furnace, but for production work it is best to use sintered linings. A flux is usually required in order to cause sintering. Boric acid is frequently used for this purpose. It is necessary to have properly graded materials, as powders containing particles of only one size do not bond well. Microscopic examination of used linings indicated that the slag frequently attacked the bonding material. Methods for testing linings are discussed. Contains 9 references. JLG(24)

Metallurgical Refractories. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, page 245.

An abstract from an article by J. F. Hyslop on the subject of "High-Alumina Firebricks," in which some discussion of the resistance of these refractories to temperature, to solution and disintegration by fluxes and dust-laden gases, and to rapid temperature changes is given. The relation of the cost of production of high-alumina refractories to alumina content is briefly described. OWE(24)

Special Refractories for Use at High Temperatures. WM. H. SWANGER & FRANK R. CALDWELL. *Bureau of Standards Journal of Research*, Vol. 6, June 1931, pages 1131–1143.

The choice of the most suitable refractory for the laboratory melting of pure metals at temperatures from 1700° up to 2200° C. without detrimental contamination of the metal by the refractory depends upon a number of factors, such as the stability of the refractory at the higher temperatures, the means available for forming and firing of crucibles, the type of melting furnace, chemical action of the particular metal in question, etc. Methods are described in detail for the preparation of crucibles and other shapes from the oxides of thorium, magnesium, zirconium and beryllium. Thorium oxide, with a melting point above 3000°, is the most refractory of the 4 oxides named. The method used for fusing this oxide is described. Crucibles made of fused thorium oxide have been used in the determinations of the melting points of platinum and rhodium. Crucibles of the commercial fused magnesium oxide are not satisfactory for work with metals of the highest purity, but crucibles prepared from the so-called "C. P." or reagent grade of powdered magnesium oxide have been used at temperatures up to 2000° C. without detrimental effect upon the metal melted. The commercial electrically fused or sintered zirconium oxide contains small amounts of silica. Crucibles of this material have been used at temperatures up to 2000° C., but unless the melting is done in air, there is danger of contamination of the metal by the silicon in the refractory. From a few experiments made with a small amount of the very pure oxide there are indications that, if available commercially, beryllium oxide might be a satisfactory refractory for use at high temperatures. GASES IN METALS (25)

Oxygen in Steel. MARCUS A. GROSSMAN (Republic Research Corp.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 601–631; *Metal Progress*, Vol. 18, Nov. 1930, pages 33–37, 102–106.

Fifth Edward De Mille Campbell Memorial Lecture presented at the 12th Annual Convention of the Society, Chicago, Sept. 1930. Includes 19 references, is illustrated with 15 micrographs, 8 photographs of macrostructures, 5 tables of analytical data and 2 graphs. The author discusses methods of determining the oxygen in steel. The vacuum method is most satisfactory and determines the total oxygen. The occurrence of oxygen in various forms in steel is discussed. Several hundred analyses show the normal amount of oxygen present in steel to vary according to composition and method of making. Representative analyses show a range of .006–.060%. Oxygen in certain forms affects the behavior of carbon in steel, rate of hardening, decarburization and microstructure. Pack carburizing results in an increase in the oxygen content of steel. Steels where this ncrease is greatest show the separation of the pearlite characteristic of structural "abnormality." A very slow cooling rate, 5000 minutes will produce in normal steel the same separation produced in an abnormal one by cooling in 1 minute from the carburizing temperature. Carburizing in methane suppresses the gain in oxygen content and the structural abnormality. A steel which absorbed .071% oxygen in pack carburizing with almost complete separation of the pearlite showed an increase of .002% oxygen when carburized in methane and a perfectly normal pearlite. WLC(25)

Alloys of Iron and Oxygen. C. H. HERTY, JR. (U. S. Bureau of Mines). *Metal Progress*, Vol. 19, June 1931, pages 99–100.

8 references to the literature are cited. Discusses the constitutional diagram published in April issue by Mathewson and the effect of iron oxide on the properties of steel. WLC(25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Manganese-Free Zirconium-Treated Steels. FREDERICK BECKET. *Mining & Metallurgy*, Vol. 12, May 1931, pages 234–236.

Results of tests show interesting possibilities in the use of Zr. Read before Iron and Steel Div. of A. I. M. E. Gives results of investigation to determine whether normal plain C steels of widely varying C and S contents and some alloy steels could be successfully fabricated if substantially free from Mn, but treated with Zr, and secondly to determine the physical and other properties of these steels. VSP(27)

Effect of Lead on Brass and Bronze. H. P. CROFT (Chase Brass & Copper Co.). *Metal Progress*, Vol. 19, May 1931, pages 60–65.

Forging brass for free machining is held to 1.5 to 2.0% Pb. Lead does not impair the physical properties and improves the machinability within this range. In amounts over 2%, lead improves corrosion resistance of brass and bronze but with some impairment of physical properties due to intergranular weakness. For deep drawing and welding applications lead should be kept to a minimum. Graphic and tabulated data on the effect of lead on season cracking, bend test, tensile strength, elongation, and machinability are given. WLC(27)

The Action of Phosphorus and Oxygen in Copper-Tin Heats and Alloys. (Ueber das Verhalten von Phosphor und Sauerstoff in Cu-Sn-Schmelzen und- Legierungen.) RICHARD FALKENSTORFER. *Metallwirtschaft*, Vol. 10, Feb. 13, 1931, pages 130–131.

Contains 11 references. The alloy Cu 85, Sn 8, Zn 5, Pb 2, with P from 0 to .63, was cast under reducing conditions at 1080° in green sand molds into 1" diameter test bars. Both tensile strength and elongation increase slightly with rising P content up to .12%, then drop sharply and remain fairly constant with higher P. Microscopic specimens were annealed for 8 hours at 700° and furnace cooled. Up to .15 P the structure was completely homogeneous. From .21 P up the phosphide eutectic was present in increasing amounts. Up to .12 P the fracture was intracrystalline, with .15 P it was intercrystalline. The higher the P the more the mold sand burns on due to the reducing action of P. With P over .15 "blossom" formation takes place on the risers due to the low melting point of the phosphide eutectic. No P is volatilized holding the melt for 25 minutes at 1100° and the maximum Zn loss was .3%. If this alloy containing .1 P is exposed to the air intermittent oxidation and reduction by P takes place until all but a trace of P is removed from the melt. If a substance is present which has greater affinity for O than P, such as Al, a permanent oxide skin is formed over the metal in spite of the P. P will reduce a badly oxidized Cu-Sn alloy. The alloy containing 5% Zn will be free from SnO_2 due to reduction by the Zn, even if SnO_2 is added under oxidizing conditions. Oxidized bronze containing traces of SnO_2 had the same tensile strength and elongation, but lower corrosion resistance and endurance limit. CEM(27)

Influence of Small Quantities of Foreign Metals upon the Properties of Refined Zinc. (Einfluss geringer Mengen von Fremdmetallen auf die Eigenschaften von Raffinadezink.) O. BAUER & P. ZUNKER. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 37–46.

Includes discussion. The influence of small quantities of Cd, Cu, Zn, Fe, Sb, Mg and P upon the contraction (from the liquid state), impact strength, and Brinell hardness of "refined zinc" (Pb = 1.12%, Cd = 0.11%, Fe = 0.03%, Cu = 0.002%) was studied. The results were compared to those of "pure zinc" (Cd = 0.019%, Pb = 0.014, Cu = 0.001%). Reviews of published work on the constitution of the binary systems of the above named metals with Zn are given, and for each system new data are given for the contraction (linear) from the liquid state, impact strength and Brinell hardness, in each case from 0 to 3 weight % of the added metal. From the data it is concluded that Sn is the most suitable metal to be added to Zn intended for casting purposes. Sn diminishes the contraction of Zn very considerably while only slightly decreasing the impact strength with small additions of Sn and actually increasing it between 1 and 3%. The hardness remains little affected. Mg diminishes the contraction as strongly as Sn, but the impact strength diminishes greatly, while the hardness rises. Thus Zn castings with Mg are brittle and hard. Cd likewise diminishes the contraction. The effect is small at low concentrations of Cd, but approaches that of Sn and Mg at higher concentrations (2–3%). The impact strength and hardness are but little affected. Small quantities of Sb diminish the contraction greatly but larger amounts are proportionately less effective. Sb exerts but little influence upon the impact strength and the hardness. Cu affects the contraction very little, but the impact strength and hardness are both considerably increased. Pb is practically without effect upon the 3 properties studied. Fe in general is favorable. Its influence upon contraction is slight, but the impact strength is greatly decreased and the hardness increased. The casting is thus harder and more brittle without concomitant diminution of the shrinkage as with Mg. RFM + EF(27)

Malleable Iron Alloyed with Nickel and Chromium. (Nickel- und Chromlegierter Temperguss.) R. WENTRUP & W. STENGER. *Die Giesserei*, Vol. 18, Jan. 2, 1931, pages 24–28.

The influence of Ni (0.5–1.8%) and Cr (0.08–0.22%) on the cementite decomposition in the production of malleable cast Fe is investigated dilatometrically, the Fe samples being annealed at temperatures up to 940° C. for 10 hours. When present in amounts up to 1%, Ni has no great influence on the decomposition, but at 1.8% it promotes the decomposition considerably. Cr has an inhibiting effect on the decomposition even when present in small amounts, being practically prevented by 0.22% Cr. In a malleable Fe containing both Ni and Cr, the disadvantageous action of Cr is removed to a considerable degree by Ni. Microphotographs (6) of various stages of the carbide decomposition are given. (27)

INSTRUMENTS & CONTROLLERS (28)

Note on Copper Constantan Thermocouple Calibration Below 0° C. R. WIEBE & M. J. BREVOORT. *Bureau of Mines Report of Investigations* 3077, Mar. 1931, 7 pages.

The deviation curve in connection with Adams or Southard and Andrews data from 0° to −193° C. for copper constantan thermocouples calibrated at the normal sublimation point of CO_2 and the normal boiling point of oxygen can apparently be represented by a quadratic equation, Deviation = $ae-be^2$ with an accuracy of about 0.05° C. AHE(28)

Heat Conductivity Values of Plate-Shaped Bodies. (Wärmeleitzahlen-plattenförmunger Korper.) S. GELIUS. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 21, 1931, pages 369–370.

At first, the influence of the shape of plates used for measuring the heat conductivity was investigated. It is stated that square plates are better for plates of more than 30 mm. while round plates are more suitable for thinner plates, down to 3 mm. The agreement of both types was about 1.5%. The accuracy of measurements is well within the limits permitted in the rules for testing heat and cold insulation equipment. Ha(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Alloys for Use at High Temperatures. W. ROSENHAIN & C. H. M. JENKINS. *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1233–1234.

Abstract of paper read before Iron & Steel Institute. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 686. MS(29)

The Mechanical Properties of Metals at Elevated Temperatures. P. CHEVENARD (Soc. Anon. Commentry-Fourchambault et Decazeville). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 155–178, 17 figures, 14 references.

Phenomena that are properly neglected as minor in industrial use of alloys for ordinary purposes cannot be neglected in certain special uses. Internal friction of metals is usually neglected, but the logarithmic-decrement is never zero so there is no true limit of elasticity. The decrement increases with temperature. The modulus, the thermo elastic coefficient and the internal friction are extraordinarily sensitive to the past history of the metal. Alloying additions do not produce major changes in modulus, but have vast effect on the decrement. Alloys and especially annealed alloys are more nearly elastic solid than are pure metals, especially when cold worked. Isothermic viscosity tests on fine wire show that metals pass progressively from the type with solid friction to the viscous type. In some conditions metal which has flowed is less likely to flow, it is work hardened. Under others it is more likely to flow, has negative work-hardening. The rate of deformation increases in exponential fashion with increase of load or of temperature. Hence rate is best expressed by a logarithmic function. On a 3-dimensioned diagram the surface showing temperature load and the logarithm of flow rate, is a hyperbolic paraboloid. The load-temperature curves for a given rate are equilateral hyperbolas. These relations are a first approximation. Study of viscosity under constant load at increasing temperature, (heating 250° C. per hour with differential compensation for thermal expansion) gives information rapidly. Such curves are given for a series of Ni-Cr alloys. Alloying produces rigidity, but the first addition is more potent than following ones. A combination of several alloying conditions is therefore advantageous. Very good results are obtained with Ni-Cr-Mo steels for use at 500° C. For higher temperatures alloying unaffected by heat-treatment are indicated, especially high Ni alloys plus Cr, W, etc. All metallurgists know that the limit of rigidity for practical use is the stress which, at the end of a given time produces a given elongation with a rate of extension less than a given value. It remains for them to standardize on the duration, elongation and rate. It has been thought by some that if the elongation could be measured with a very sensitive extensometer the time could be reduced to a few hours. It is prudent to adopt, at least provisionally, a much longer duration of test, since metallographic changes may occur that take place slowly. HWG(29)

The Performances of Cast Carbon and Low Alloy Steels in High- and Low-Temperature Service. R. A. BULL (Electric Steel Founders' Research Group). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 260–298, 23 figures, 27 references.

Cast steel parts are applied to high temperature uses, especially in power plants and oil refineries. If made conservatively thick, carbon steel castings act well up to 750° F. Low Ni-Cr cast steels perform well up to 1000° F. Railroad service, tractors, trucks and aircraft may use steel castings at very low temperatures. All available low temperature data are tabulated. Quenched and drawn carbon steel has less low temperature brittleness than when normalized. Ni or Ni plus V as alloy greatly improves low-temperature impact resistance of cast steel.

In high temperature service, cast steel of 0.30–0.40% C, 2% Ni, 0.8% Cr shows results much superior to carbon steel. Hitherto unpublished data on carbon, manganese-carbon and Ni-Cr cast steel are given. Comparison of 0.35% C, 1.42% Mn; and 0.48% C., 1.24% Ni, 0.80% Cr cast steels in creep tests showed that at 25,000 lbs./in.^{2} and 850° F., 10,000 lbs./in.^{2} and 1000° F. the Mn-C steel crept less for 500 or 600 hours, but then the curves cross and after that the Ni Cr was superior. Data from the General Electric Co. indicate that of a 0.44% C, 0.65% Mn, 1.2% Ni, 0.5% Cr; a 0.33% C, 1% Mn, 0.25% V and a 0.33% C, 1% Mn, 0.30% Mo steel the Mn-Mo steel was superior, creep stress to give 1% flow in 100,000 hrs. being, NiCr, about 10,000; Mn-V, about 6000 and Mn-Mo, about 15,000 lbs./in.^{2} at 840° F. At 930° F. the Mn-Mo steel gave about 12,500 lbs./in.^{2} while the Mn-V was down to 2500. A Cr-W combination is alleged to work well but nothing but propaganda is available on it, engineering data being lacking. At and above the equi-cohesive temperature, about 1000° F., large grain size, as in cast steel, gives much better creep resistance than small grain size, as in wrought material. Discrepancies in creep test results and in different makers claims are commented on. Generally the least optimistic data are the more reliable. The desirability of accelerated test methods is brought out. Much pertinent comment is made on the necessity of proper design in steel castings for high temperature service, to avoid failure from defects due to casting difficulties arising from wrong design, and in order fully to utilize the inherent properties of the steel. Steel foundry technique is more vital in producing service castings than is the chemical composition. HWG(29)

Engineering Requirements and Trends for Metals in the Non-ferrous Roasting, Smelting and Refining Industry. R. E. BROWN (Electro Metallurgical Corporation). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 77–94.

Because of the prevalence of sulphide ores, non-ferrous smelting has a special high temperatures sulphur corrosion problem added to those of oxidation and structural strength. This leads to avoidance of Ni and the use of Cr alloys. For rabble arms and blades of roasting furnaces, cast alloys of about 0.80 C, 17 Cr, or 1.10 C, 23 Cr are used. Abrasion and oxidation resistance and resistance to S and As and their compounds at 1500° F. are required for copper sulphide concentrates. Hearths of similar properties able to support a live load of 50 lbs./ft.^{2} are being tried. Dwight Lloyd sintering machines operate at 800° to 1500° F., and are all steel. Prospects are good for extensive use of heat-resisting alloys. Steel bins and hoppers for hot calcines and steel or cast iron stirrers for them oxidize rapidly at 1200–1400° F. 18 Cr, 8 Ni or 24 Cr, 11 Ni work well, the Ni not being harmful. High Cr Mn alloys are promising. Reverberatories for solid fuel use Ni Cr cast iron or Cr white iron, grate bars; those using oil or gas have high Ni Cr or Cr alloys in the burners. Highest quality alloys are required as they get very hot. Slag skimmers of high C high Cr are promising. Alloy molds for casting copper anodes are suggested to replace cast iron. Scrap could be used in making grinding-mill balls. Metal retorts for zinc smelting are impractical, but oxidation-resistant alloys might be useful for condensers. Zinc melting pots of 2½ Ni, 1½ Cr with 0.90 combined C seem somewhat better than ordinary cast iron. Similar pots are good for Pb, with temperatures below 1400° F. Plates for Cottrell precipitators in fume recovery, with gases at 275° F. or below, are subject to corrosion. Pb or Al are used. Cast iron tubes used in distilling Au Hg amalgam do not last long; a close grained iron that is resistant to oxidation and to cracking is needed. HWG(29)

Heat Treatment and Effect of Heat on Metallic Bodies. BRADLEY STOUGHTON & ALLISON BUTTS. *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1217–1233.

Constitutes an addition to the new edition of authors' "Engineering Metallurgy." Deals with properties of metals at different temperatures, grain growth and recrystallization, heat treatment for the purpose of hardening steel, annealing of steel, chilling cast-iron for hardness and heat treating steel and non-ferrous alloys for strength. MS(29)

Working Stresses for Steel at High Temperatures. Paper No. FSP-52-35. D. S. JACOBUS. *Transactions American Society Mechanical Engineers.* Vol. 52, Sept.-Dec., 1930, pages 295–304.

Some published results for stress to produce creep at higher temperatures have led to apprehension, which it is the object of the paper to dispel for the particular stresses which are discussed. The results secured in practical experience are used for setting the maximum working stresses for drums and superheater headers up to temperatures of 800° F., and for temperatures above 800° F., the working stresses are scaled down in proportion to the falling off of the stresses that produce creep. The first curve of creep stresses published by H. J. French of the Bureau of Standards was used, and the working stresses for a given temperature are taken at ⅔ the creep stress. The effect on the stress of piercing a boiler shell with holes and of transmitting heat through the shell is discussed, as well as the tendency toward equalization of stress through extension of the most-strained fiber. The tendency of the creep to equalize the stresses is also brought out. The method of extrapolation used by different authorities is discussed, and the conclusion is reached that more exact results are obtained by using the method employed by Prof. F. H. Norton in his book on the "Creep of Steel at High Temperatures" than by some other methods. 12 abstracted references. MFB(29)

The Expansion of Metals at High Temperatures. FDK. L. UFFELMANN. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Oct. 1930, pages 633–659.

Describes an optical interference method for measurements in 3 perpendicular directions on the same specimen and for use up to 800° C. Continuous temperature variation is made possible by a device for equalizing the temperature lag of the platinum resistance thermometer and the specimen. Observations were made during both heating and cooling. Results are given for Sn, Cd, Zn, Pb, Al, Cu, Co, Ni, brass and steel. Sn, Cd and Zn show pronounced anisotropic properties and over extended temperature ranges the cubical expansion coefficient curves fit neither the Quadratic nor Thieson's formula. Expansion coefficient curve for lead has definite changes at 170° C. and 245° C. The mean Al and Cu curves fit the quadratic relation. Brass with a maximum at 460° C. does not fit. For Co, Ni and steel, the expansion coefficient curve during heating is different from that during cooling, Co showing a sharp peak at 450° C. on heating and at 350° C. on cooling. Ni has a maximum in the heating curve at 340–360° C. RHP(29)

Needs of the Oil Industry for Metals at High Temperatures. E. S. DIXON (Texas Company). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 23–41, 3 tables.

Requirements for stills, cracking units, piping, hot oil pumps, etc., are summarized on the basis of a questionnaire to 270 refineries and equipment makers. Maximum, continuous temperatures (7 to 40 days) in pressure still work are reported from 775° to 1200° F., with one at 1400° F., maximum short-time temperatures (15 minutes to 2 hours) 1350° to 1500° F. with one report of 1775° F. Pressure varies from 335 to 1200 lbs. High temperatures are important for economy. Better material than KA2S is desired. Thermal conductivity is discussed in 18 replies, 10 calling it an important factor. Thermal expansion of high temperature alloys equal to that of carbon steel is desired by 8, while 7 think a different coefficient can be utilized by proper design. Resistance to fatigue, or repeated stress at high temperatures better than that of carbon steel is desired by 6, while 6 believe that creep and not fatigue, is the determining factor. Allowable stresses are discussed in 15 replies, with widely varying opinions. Some use the creep stress for 1% per year, with some factor of safety. Several use 6000 lbs./in.^{2} at 900° F. for carbon steel, and one reply gives 16,000 lbs./in.^{2} at 900° F. for 18–8. At higher temperatures, opinions vary, covering 2100 lbs./in.^{2} at 110° F., 4000 at 1200° F., 2000 at 1300° F., 4000 to 5000 at 1400° F. is said to be desired, though that stress is not now used. Fourteen replies give their own tonnage requirements for alloy tubes at a total of 19,000 tons. Of the replies, 23 reported corrosion by sulphur or its compounds, 8 erosion, 7 scaling, 6 acid corrosion, 2 each flue gas corrosion, caustic embrittlement, hydrogen embrittlement and general corrosion, 3 HCl corrosion, 1 no corrosion. 28 replies wanted the high temperature alloys readily weldable, 15 thought it desirable, but not imperative. 23 state that tubes must be rolled in, and material must stand it without work hardening. All replies desire that tubes swell before rupture, so as to give warning, which is not given by 18–8, but a few are willing to sacrifice such warning to obtain other outstanding properties. Large differences in practice and requirements among refineries are evident from this survey. HWG(29)

Properties of Bearing Metals at Normal and Elevated Temperatures. E. R. DARBY (Federal Mogul Corp.). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 218–233. 16 references, 6 figures, 3 tables.

Bearings often operate at temperature above atmospheric and their usefulness depends on their properties at those temperatures. Rolling mill bearings may operate at really high temperatures, but ordinary bearings may run at 100° to 300° F. In comparison to the melting points of the white metal bearings, say 400° to 500° F. and since some contain constituents that melt below 400° F., the operating temperatures are high. Room temperature properties are not safe guides. Especially in the automotive field, bearing duty is becoming so severe and operating temperatures so high, that the margin of safety on white metals is seriously reduced. Since the operating temperature is at least partly due to the bearing's own friction, the frictional and wear-resisting properties of bearing metals are important. Resistance to pounding, strength, hardness and toughness at operating temperatures are measures of the load carrying ability of the bearing. The bulk of the work on bronze bearings at elevated temperatures has been done at the Bureau of Standards, and the results are summarized. The tensile strength and elongation of bearing bronzes with 5 to 10% Sn, 5 to 18% Pb, both fall off sharply above 500° F. Resistance to pounding and impact resistance of sand cast Cu-Sn-Pb bronzes at 350° and 600° F. are higher than on chill cast. At these temperatures addition of Pb beyond 10% rapidly decreases, and addition of Sn beyond 6% rapidly increases, resistance to pounding. Addition of 4% Zn has little effect on high temperature properties; 0.05% P or 2% Ni decreased the resistance to pounding at 600° F. The tin base and lead base alloys lose strength and hardness very rapidly with increasing temperature. Tin base alloys containing lead "wipe" slightly below 360° F. the melting point of the Pb-Sn eutectic. Such low-melting impurities are harmful. The alkali and alkaline-earth-hardened leads have higher hardness at 325° F. than the usual tin or lead base alloys, but are not in general use in this country. Available data on high temperature properties of bronzes, of tin base and of lead base bearing metals are tabulated. HWG(29)

The Trend of Progress in Great Britain on the Engineering Use of Metals at Elevated Temperatures. R. W. BAILEY (Metropolitan Vickers), J. H. S. DICKENSON (English Steel Corporation), N. P. INGLIS & J. L. PEARSON (Synthetic Ammonia & Nitrates), *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 136–154, 4 references.

English metallurgists are interested in accelerated methods for determining creep, and some individuals advocate definite methods. Bailey *et al.* state, however, that these methods are only on trial. The desirable attributes of alloys for high temperature service are listed. Combination of all the attributes is unobtainable and the choice must be made on the basis of the most important requisites. Nickel does not, in itself, improve high temperature load carrying ability of steel. Of low alloy steels, 1% Cr, 1/4% V is good to 750° F. One of 2 1/2% Ni, 0.7% Cr, 0.3% Mo is good to 930° F. Above these temperatures, the steels have high creep. Plain 0.15% C, 0.35% Mo steel has remarkably high creep resistance to 1020° F. and its extended use is anticipated. Increase in Cr increases creep resistance and adds corrosion resistance. Austenitic Ni Cr steels have attractive creep resistance to 1110° F., but are prone to intercrystalline fissuring if heated in the range 930–1560° F. Tungsten helps. Automotive engine valves for heavy duty are trending toward use of austenitic Ni Cr steels in England. Embrittlement by many cycles of heating to 730° or 840° F. occurs in heat-treated mild steel. Nickel makes it worse. Sufficient molybdenum cures it. No steel which suffers from this effect should be used for parts stressed at high temperatures. High silicon cast iron with fine graphite resists growth and oxidation to 1650° F. Mild steel scales badly above 930° F. A 7 1/2% Cr steel, with carbon below 0.12% and perhaps with silicon up to 1% has good scaling resistance to 1290° F. above which the heat-resistant steels and alloys are required. The cast 65-20-15 Ni, Cr, Fe alloys must be cast sound for good service. Cast Ni, Cr, Al alloys are suggested for use to 2000° F. in sulphur gases. A plain 30% Cr is very resistant to oxidation and to sulphur, but is brittle cold. In Pilger mill mandrels and in extrusion presses, Ni, Cr or Ni-Cr alloys with Mo or W, usually Mo unless high red hardness is needed, are useful. For successfully coping with high temperature problems, engineers must rid themselves of the "mild steel complex." They must also go beyond the elastic theory in design. Creep data must be utilized. But data from different investigators and by different methods show wide divergence. Mathematical relationships between creep in tension and in shear are discussed in detail. There is need for more data on the thermal conductivity of alloys at 750° to 1250° F.

HWG(29)

Use of Metals at Elevated Temperatures in the Ceramic Industry. C. E. WILLIAMS (Battelle Memorial Institute). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 120–135, 8 references.

Drying ceramic materials at 300–500° F. before firing involves corrosion troubles, but high priced alloys are not warranted. Firing temperatures range from 1600° F. for common brick to 1775° F. for porcelain pyrometer tubes. Metal parts in kilns, sand seal plates, flue dampers, pans, kiln furniture, etc., are subjected to high temperature corrosion. Coal with 5% S is often used for ceramic firing. Fan blades for induced draft kilns are a special problem, with 18–8 on trial. Refractories reinforced with 0.20 C, 25 Cr, 17 Ni are being tried. A 28 Cr alloy became brittle. Cars for tunnel kilns may reach 1200° F. at the top, and only 400° F. at the bottom. Enormous expansion strains are set up and steel distorts. Cast iron in the upper sections has worked well. Design that allows free expansion is essential. For sand-seal plates, rolled steel, mounted to allow expansion and covered with a refractory wash, are adequate. Kiln "furniture," props, supports, etc., must not scale or deform up to 1650° F. For china, burnt above 2050° F., refractory furniture must be used. Electric furnaces would be ideal for china, but present metallic resistors will not serve. Vitreous enameling goes up to 1500° for cast iron and 1800° F. for steel. Supports reach higher temperatures and the furnace itself may be several hundred degrees higher. No scaling or deformation of supports is allowable. Points must be kept sharp by grinding. The alloys should be weldable. Some enamels appear to attack the temperature-resistant alloys. 18–8 scales, and calorizing it is being tried. Alloys of 67 Ni, 20 Cr; 60 Ni, 30 Cr; 20 Ni, 32 Cr; and 37 Ni, 18 Cr are all in use. Warpage is bad, as a warped support has to be straightened; this ultimately causes breakage. Making supports symmetrical and turning them over from time to time helps. Monel cast iron (14 Ni, 6 Cu, 2 Cr) supports used at 1560° F. outlast ordinary cast iron 10 or more to 1. In the glass industry, plungers to force the glass into molds, may be made of cast iron with 3% Ni, but are hard to cast free from blowholes. Cr plating or use of 65 Ni, 15 Cr is promising. Glass molds must be machinable, not stick to the glass, take a polish, operate at 900–1100° F. with the face at 1800–2400° F. Gray iron with a somewhat chilled surface is used. Monel cast iron, (Ni-resist), and 3 to 5% Ni cast iron are in use. Steel of 0.20 C, 0.75 Ni, 14% Cr is said to be good. High Ni-Cr alloys have not made much headway. Cr plating on heat-treated, high-test cast iron is quite successful. Various alloys, Monel cast iron (Ni-resist) and 60 Ni, 30 Cr or Cr plating are in use for sheet and plate glass rolls and tables. In lehrs heated by sulphur-bearing fuel, operating at 1000–1400° F., cast iron has behaved better than the Ni Cr alloys. Still better results are obtained with Ni-resist cast iron. Muffles in indirect fired lehrs must stand over 2000° F. Here 65 Ni, 15 Cr or steel with 0.25 C, 0.50 Ni, 28 Cr is used. Driving chains in continuous lehrs are of malleable iron or cast iron with 3 to 7% Ni, 1 1/2 to 3 1/2 Cu. Lehr rollers for plate glass of mild steel Cr plated have given very good results. The glass industry needs a metallic pyrometer protection tube to stand continuous immersion at 2000° F.

Seek Metals to Withstand Higher Temperatures. *Steel*, Vol. 89, July 2, 1931, page 48.

A brief article describing the symposium on Effect of Temperature on the Properties of Metals, presented in Chicago, on June 23, 1931.

WAT(29)

Power Station Temperatures and Tensile Strength. *Metal Industry*, London, Vol. 38, June 19, 1931, pages 617–618.

A brief résumé of the subject. The tensile strength of a 0.37 C steel is given at 900° C., yield point and proportional limit values are given to 500° C. Tensile strength values are given on a manganese bronze and a gunmetal to 450° C. Corrosion and creep encountered in power stations are discussed very briefly. An interesting table is given showing temperature and pressure increases in power station practice since 1912. The maximum pressure in 1912 was 275 lbs./in.^{2} at 506° F. In 1930 a pressure of 1568 lbs./in.^{2} was reached in Vitkovice, Czechoslovakia, at 932° F. One experimental plant (location not given) has reached a pressure of 3200 lbs./in.^{2} at 706° F. In this connection there is an interesting article in *Power*, June 30, 1931, pages 1028–1031, which states that the steel works at Vitkovice are now planning to operate at 1900 lbs./in.^{2} at 900° F. The article describes the values and boiler fittings, from a standpoint of design rather than material used. The type of steel was not given other than one having a tensile strength of 78,000–92,000 lbs./in.^{2} and being rustless.

WAT(29)

Engineering Requirements in the Automotive Industry for Metals Operating at High Temperatures. A. L. BOEGEHOLD (General Motors Company) and J. B. JOHNSON (Army Air Corps). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 95–119, 11 tables, 15 references.

Requirements of pistons are tabulated. Cast iron and aluminum alloys each have advantages. Maximum piston head temperatures are 700° F. for Al, 900° F. for cast iron. Methods of compensating for high thermal expansion of Al are discussed. An Al alloy with 14 Si, 2 Ni, 1 Mg and 3/4 Cu has a relatively low coefficient. This also has good wear resistance. If used in cylinder sleeves of cast iron containing 14 Ni, 6 Cu and 2 Cr, which has a high coefficient, mutual expansion difficulties are minimized. 7 alloys for Al pistons are listed, as are 3 cast irons. These 3 contain either 0.35 Mo, 0.15 Ni or 0.30 Cr. In small bore, multicylinder engines, cast iron pistons have advantages over Al. Mg alloy pistons have no advantages over Al. An 80 Be, 30 Al piston would be ideal if beryllium were cheap enough. Valves in proper design may reach 1000° to 1450° F. and under unfavorable conditions, 1500° to 1600° F. If the valve stem could be sufficiently work-hardened, austenitic corrosion resistant steels would make the best valves. Most valve steels for severe conditions contain 0.40 to 0.60 C, about 9% Cr, 3 1/2 Si, and are improved by addition of 1/2% W. High temperature strength is satisfactory, but corrosion resistance to exhaust gases from fuels treated to eliminate knock needs improvement. Cylinders have greatest difficulty in valve seat wear. With proper lubrication and air cleaning cylinder wear is negligible. A dozen compositions of cylinder iron are tabulated, mostly containing Ni and Cr. Valve springs operate a 175–250° F. Failure is by fatigue, and is prevented by proper design. 5 steel compositions are mentioned. 9 piston bearing bronzes are listed, that are used with cast iron pistons at 300° F. Connecting rod and main crankshaft bearings have the most severe service of any in the auto, with shock loads of 2000 lbs./in.^{2} projected area, and run up to 400° F. with rubbing speed up to 2750 ft./min. Babbitt bearings, operated near 400° F. soon fail, as their high temperature strength is low. Failures of tin base babbitt with 7 1/2 Sb, 7 1/2 Cu are common. Reducing the lining thickness to 1/32" or less is helpful, since deflection or permanent set is reduced and heat dissipation facilitated. Even this will not cure failure on some engines, and it is necessary to keep lead out. The hard babbitt without Pb has 1600 lbs./in.^{2} tensile, and 116% elongation at 400° F. If 2% Pb is introduced, the figures fall to 500 lbs./in.^{2} and 1%. Bi in a Sn-base babbitt is very harmful. Resistance to shock and cracking is improved by cutting Cu below 7 1/2%. The trend to higher bearing loads will soon make it necessary to abandon the babbitts and go to bearing metals of higher melting points. Diesel engine pistons need high head temperatures so cast iron is used in small ones. In large, internal cooling or use of Al, is required. The high explosion temperature makes it hard on valves if there is leakage. Very high strength iron is needed for cylinder and cylinder head, and there is danger of cracking from differential expansion. Aviation engine pistons may operate at 650° F., exhaust valves at 1600° F., air cooled cylinder heads at 600° F. Compositions and physical properties are given for these and other parts. Valve seats and guides may be of aluminum bronze, containing Fe or Fe and Ni. Austenitic Ni Cr steels have suitable properties also. Cylinder heads are Al alloys, 3 compositions being given. Mg alloys have too low strength and thermal conductivity. Cylinder barrels are 0.50 C steel. Some other alloys tried showed too much wear. Nitrided cylinders are being used in France. Corrosion resistance against doped fuels is essential. Aircraft pistons are always Al alloys. Valves may be of Cr-Si-W steel. Several other compositions are referred to, and a list of detailed requirements given. Corrosion of exhaust stacks is a problem. 18–8 is generally used. High bearing pressures and temperatures have called for steel backs on babbitt bearings, to give stiffness, and this combination has been replaced with alloys containing 25 to 38% Pb, 1/4 to 5% Sn, balance Cu. HWG(29)

Nickel and Nickel Alloys, Other than the Nickel-Chromium-Iron Group (at High Temperatures). C. A. CRAWFORD & R. WORTHINGTON (International Nickel Co.). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 403–431, 23 figures, 23 references.

What might be termed the "non-ferrous" nickel alloys are considered in this paper, especially commercial Ni, Monel, Ni Cu, and Ni Cu Zn alloys. These have creep resistance better than most other copper alloys, but below that of carbon or alloy steels, or the NiCr Fe heat resisting alloys. On account of their corrosion resistance they serve for the lower range of high temperature service. Available data are plotted. Ni and Monel are more resistant to creep than the other alloys in this class, but it is not known which has the better resistance, nor are the high temperature effects of addition elements well understood. Cold worked material not heated to its recrystallization temperature, retains its strength at lower temperatures and may even harden somewhat. The recrystallization temperature depends on the degree of cold work. Up to the recrystallization temperature, short time tensile tests have value. They also have value in revealing hot-short ranges and in showing workability at very high temperatures. Above some 600° F., creep tests show lower load carrying ability than would be expected from short time tests. Resistance of the alloys to oxidation, to alternate oxidizing and reducing conditions, to attack by steam, by hydrogen and nitrogen, as in nitriding containers, to sulphidization under oxidizing and reducing conditions and to attack by molten metals is discussed. HWG(29)

Effect of Elevated Temperatures on Certain Mechanical Properties of Gray Cast Iron and Malleable Iron. J. W. BOLTON (Lukenheimer Co.) & H. BORNSTEIN (Deere & Co.). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 299–321, 60 references.

There are no available creep data on cast or malleable iron. Short-time tensile tests show quite constant strength and hardness to 800° F. The modulus of elasticity of cast iron is lowered as temperature rises, but does not drop much to 750° F., though it drops materially at 1000° F. The larger the cross-section of the casting the more noticeable is the temperature effect on modulus. High test cast irons hold their relative strength up to about 800° F., the curves being similar in form to those for weaker irons. Heating for 500 hrs. at 850° F., then testing at room temperatures produces only slight loss of strength, but this treatment at higher temperatures drops the strength vastly. Addition of 1/2% Cr reduces the loss of strength. "Growth" of cast iron is a serious factor in high temperature uses. This is discussed in some detail. Prevention of oxidation in use, use of white iron, of Cr and probably of W or Mo, and low total carbon, are ways of minimizing growth. It can be prevented by use of enough alloying elements to avoid allotropic transformations, as in the case of "Niresist" (14 Ni 5 Cu, 3 Cr). Raising Si to 4 to 10% is also used. Gray iron castings are allowed for pressure-containing parts up to 450° F. by the A. S. M. E. boiler code, which is conservative. Where growth is not serious gray iron may serve at 700° or even 800° F. Above that there is too much danger of graphitization. Low temperatures do not appear to increase the brittleness of cast iron. Design for low temperature service should allow for thermal contraction and consequent stress. Malleable does not grow, unless 1300° F. is exceeded. Malleable is seriously brittle at temperatures below 32° F. Conditions that lead to a malleable prone to embrittlement when galvanized bring about such brittleness at higher temperatures, while lots that are not prone to galvanizing embrittlement retain toughness to lower temperatures. HWG(29)

Bending of Curved Pipes. SABIN CROCKER (Detroit Edison Co.). *Heating, Piping and Air Conditioning*, Vol. 3, May 1931, pages 399–403.

The theories advanced by a number of investigators regarding the flattening of the circular cross section of curved pipes during flexure are supported by a comprehensive series of tests. The formulas presented by different investigators are in essential agreement. Their results taken together offer conclusive proof that flattening of the circular cross section of curved pipes during flexure must be taken into account in an accurate flexibility analysis. These formulae are presented and discussed in this paper. The theory of flattening takes into account the fact that curved pipes behave differently during flexure than do straight pipes or solid bars. It applies to initially curved pipes, such as quarter bends, U bends and the like. Briefly, flattening of curved pipes during flexure comes from the fact that tension and compression stresses induced by flexure cannot act in a straight line and consequently must have components toward the neutral axis of the cross section. The operation of piping in power plants and oil refineries at temperatures about 750° F. has led to the consideration of creep in setting up safe working stresses due either to fluid pressure or expansion. Bursting stress is not relieved by plastic flow or creep. The author's company is now basing the design of piping for temperatures in excess of 750° F. on the following considerations (a) transverse bursting stress to be kept in safe limits within limiting creep stresses of 1% in 100,000 hrs., (b) the equivalent stress = maximum stress minus minimum stress and not to exceed 15,000 lbs./in.^{2} This limit of equivalent stress is considered safe for carbon steel pipe. WAT(29)

Engineering Requirements and Trends for Metals in the Ferrous Metal Industries. J. C. WOODSON (Westinghouse Elec. & Mfg. Co.). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 51–76.

Discussion based on experiences of 22 alloy makers, furnace builders and consulting engineers. Resistor alloys for electric furnaces are 80 Ni 20 Cr, relative life 7.6; 59 Ni 16 Cr 23 Fe, relative life 3.2; 34 Ni 20 Cr 42 Fe, relative life, unity. Cast resistors are 67 Ni 20 Cr 13 Fe for high temperatures, 37 Ni 19 Cr 44 Fe, for lower ones. Expansion, creep and growth are the main difficulties. The alloys serve very satisfactorily, but other alloys to give furnace temperatures of 2000–2500° F. are needed. Ovens operating up to 850° F. have some difficulties due to moisture condensation and rusting during shut-downs. Ingot iron serves to 600° F., above that stainless steel (11–14 Cr) is advisable. Lead, solder, tin type metal and babbitt pots are cast iron or cast steel. These are attacked by high-tin alloys. Ni-Cr alloys are also attacked by tin. Neither will these, or high Cr alloys, resist zinc, so galvanizing pots are made of ingot iron or boiler plate. Failure is due more to operating conditions than to material of the pot. Precautions are given. Pot life with pots 1½ to 2″ thick is 1 to 6 months. Improvements are needed. Aluminum melting pots are cast iron. Ni-Cr alloys are attacked. Fire box temperature is 1700–2000° F., excessive for cast iron, so the pots grow, blister and crack. Improvement should be possible. Structural parts for heat-treating furnaces are made in a wide variety of compositions. In one group the Cr is about 15 to 20% with Ni ranging from 80 to 20% with about 37 Ni, 19 Cr most widely used. Where presence of nickel in large amounts is detrimental due to special corrosive conditions, the Ni may run 6 to 20%, being used for ductility, with Cr from 18 to 30%. The Cr-Fe alloys are also used. Woodson prefers the 37 Ni, 19 Cr alloy unless corrosive conditions are present, but some makers believe that 42 Cr, 12 Ni is just as good. The furnace atmosphere (oxidizing, neutral, reducing or sulphur-bearing) has as much effect on life as temperature does. Nitriding furnace containers offer difficulties. Alloys with no Ni or with Cr predominating have not been as successful as pure Ni or Monel. More work is needed. Alloys for use in heat-treating furnaces, batch and conveyor types, operating at 1350–1650° F. may fail from oxidation or chemical attack if the composition is not suited to the conditions. High impinging gas velocity may wash away the protective film and this may be a greater source of trouble than temperature itself. Mechanical failures are generally due to a design which disregards the forces of thermal expansion. Design in which many small pieces are used is better than one calling for very large pieces. This is illustrated by photographs. Casting defects that would be unobjectionable at normal temperatures, may be fatal. If the ambient gas is sulphur-free, 67 Ni, 20 Cr or 37 Ni, 19 Cr are generally used. Most steel-mill furnaces use 24 Cr, 12 Ni. Some of these operate at 2000° F., but it is not recommended to go so high in general practice. In sulphur gases, 28 Cr, no Ni, is used, but is subject to embrittlement. Carburizing boxes, used at 1450–1750° F. are made of various compositions, with 60 Ni, 12 Cr apparently in the lead. With high Na_2CO_3 or in sulphur gases, 28 Cr, 10 Ni or 35 Ni, 15 Cr are used. Proper design has much to do with the life of the box. Annealing boxes are so heavy that only the cheaper 18 Cr, 8 Ni alloys are used, best in boxes fabricated from rather thin sheet. For malleabilizeing, at 1600–1850° F. white or gray cast iron or cast steel are used. Woodson suggests the use of fabricated sheet boxes, but expects that electric furnaces and short-time cycles will ultimately make boxes disappear. Pot type furnaces for lead, of 66 Ni, 20 Cr give 3000 to 6000 hours life at 1500° F. Bi or Sb in the lead accelerate corrosion. The life ought to be doubled. Cyanide pot failures are not well enough understood. Various alloys give both good and bad results. A table showing type of service, temperatures encountered and materials in use in open-hearth steel plants, covering 60 items used at 150° to 3000° F. is appended. HWG(29)

Properties of the Rare Metals for High Temperature Service. W. H. SWANGER (Bureau of Standards). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 450–462, 16 references, 1 table.

Data on physical properties of Au, Ag, Ru, Rh, Pd, Os, Ir, Pt, W, Mo, Ta and Cb are tabulated. Mechanical properties of these metals and their alloys are little known. Ru and Os oxidize readily, also Ta and Cb. Rh, Pd and Ir form oxides but the oxides dissociate at high temperatures so that the metals are serviceable for high temperature use. W and Mo are usable in reducing atmospheres or in vacuo. Some high temperature applications of several of the metals are referred to. HWG(29)

The Mechanical Properties of Aluminum and Magnesium Alloys at Elevated Temperatures. R. L. TEMPLIN & D. A. PAUL (Aluminum Co. of America). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperrture on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 198–217, 16 tables, 12 references, 16 figures.

The properties are tabulated and plotted in great detail. Most past data has been obtained by short-time tensile tests to 800° F. Data are presented for various cast and wrought aluminum alloys, heated for 50 or 100 days at 400° and 600° F., then given short-time tensile test at those temperatures, which indicate that the results of short-time tests without preliminary prolonged heating may be misleading. Growth at high temperatures is discussed. The data are too profuse for abstracting. Aluminum alloys, fortunately for aircraft uses, are not injured by low temperatures. They are unique in that both strength and ductility increase at low temperatures, even down to −320° F. All data on magnesium alloys have been obtained by short-time tests. Low temperature strength increases on pure Mg, and stays about constant on most of its alloys, but ductility and impact strength are lowered at low temperatures. At high temperatures ductility increases but strength drops rapidly, yield point even more rapidly. The available data are tabulated. HWG(29)

Experiences with Alloyed and Higher Carbonized Boiler-Plate Materials. (Erfahrungen mit legierten und höher gekohlten Kesselbaustoffen.) FIEK. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 14, 1931, pages 336–337.

The testing laboratory of the Rheinische Dampfkessel-Ueberwachungsverein has published results of tests made on some special high-grade steels for the construction of boilers. The reader is referred to tables which show the exact chemical analysis of 11 steels and the elastic limit tensile strength and elongation at 20° and 400° C. Ha(29)

Endurance of Alloy Steels in Steam. T. S. FULLER. *Metal Progress*, Vol. 20, July 1931, pages 79–81.

Advance information on a paper to be presented at the September Convention of the American Society for Steel Treating. It is an extension of the work done in the laboratory of the General Electric Company and reported in the A. I. M. E. in 1930. (See *Metals & Alloys*, Vol. 1, June 1930, page 565.) The results are presented on a Data Sheet which is included in the article. The steels tested were: 3.5% Ni, an Fe-Cr alloy with 0.10% C and 12.5% Cr, 3 nitrided steels 0.36% C 0.18% C and 0.20% C, all heat treated, and an 18–8 austenitic group with 0.065%, 0.085% and 0.15% C. Some of the conclusions are: the nickel steel and the chrome-iron alloy, in the absence of appreciable quantities of liquid water and oxygen in the steam, were not seriously affected to pressures of 220 lbs. and temperatures of 700° F.; due to the presence of liquid water and oxygen, the steam jet-atmosphere endurance values of these steels were but 41% and 54% of the corresponding air-room temperature values. In the nickel steel, if corrosion be severe, the endurance values are not a function of the initial tensile properties of the material. The damaging effect of the simultaneous presence of stress and corrosion is emphasized. Chromium plate offered considerable protection to the nickel steel against corrosion in the steam jet-atmosphere test. No damaging effect of the pre-corrosion treatment on the chrome-iron was evidenced by any of the tests. The ratio of the air-room temperature endurance limit to ultimate strength was higher in the case of the nitrided nitriding steels than in that of any of the other tested. The endurance values of the nitrided steels dropped off rapidly with increasing temperatures. The ratio of the steam jet-atmosphere to air-room temperature endurance values was higher in the case of the nitrided nitriding steels than in that of the other steels tested. The 60-lbs. 300° F. steam endurance value of notched nitrided specimens ranged from 74 to 83% of that shown by the corresponding unnotched specimens. The endurance properties of the 18–8 chrome nickel type of alloy are seriously affected by long intervals of time at temperatures of 1200° F. and above. In the hot rolled condition the endurance values of this alloy bear a relationship to carbon content. This relation, however, disappears after drastic treatment at elevated temperatures. WAT(29)

High Temperature Creep Properties of Wrought Carbon and Low Alloy Steels. A. P. SPOONER (Bethlehem Steel Co.) & F. B. FOLEY (Midvale Co.). *Preprint for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals*, June 1931 meeting *American Society for Testing Materials*, pages 255–259.

A series of 64 steels, with 0.20 to 0.50% C, some being plain carbon steels, other containing up to a total of 5% of alloying elements, Ni, Cr, W, V and Mo are tabulated in respect to stresses producing a rate of elongation of 1% in 100,000 hrs. About a quarter of the steels were tested by Hatfield or Eckhardt, with "accelerated!" tests that purport to indicate long-time creep properties but which have not yet been proven to do so. The balance were tested by long-time methods. The steels with best load carrying ability at 1000° to 1100° F. are in general those containing Cr and either W or Mo as alloying elements. A 0.38% C, 0.95% Mn, 0.57% Cr, 0.86% W steel is about as strong at 1000° F. as a plain 0.40% C steel is at 700° F. One of 0.39% C, 0.87% Cr, 0.21% Mo is as strong at 1000° F. as the 0.40% C steel is at 600° F. Data in the literature on tests at loads that produce 1% flow in 1000 hrs., or that indicate "limiting creep values" of less than 1000 lbs./in.^{2} have been omitted as of no interest from the design standpoint. HWG(29)

The Red-Brittleness of Steel by Metals. (Ueber Rotbruch des Stahls durch Metalle.) H. SCHOTTKY, K. SCHICHTEL & R. STOLLE. *Krupp'sche Monatshefte*, Vol. 12, May 1931, pages 100–105.

After a review of former investigations of this subject, tests are described in which the hot steel was bent and the metal was either strewn on or the steel was dipped in it. From the tests, the following conditions for the occurrence of red-brittleness were found: (1) direct contact of the steel with one alloy which is at least partly liquid; (2) the existence of an extensive ability to mix between the iron and the metal the principal constituent of the liquid alloy; (3) the existence of a sufficiently high tensile stress in the steel which is wetted by the metal. Many photographs and micrographs illustrate the article and 18 references are cited. Ha(29)

The Load Limit of Steam Turbines. (Die Grenzleistung von Dampfturbinen.) H. KLUGE. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Feb. 1931, pages 49–54.

Gives present-day conception of load limit, also thermodynamic calculations of load limitation blade limits, limit of blade diameter, the closest margin permissible and a table of load limits. Rather large variation in the absolute and relative velocity depending on the variation of the cross-section of the blade. Valuable equations for blades are given; they are the most dangerous part of the turbine. The final loading depends on the limit values at high temperatures. MB(29)

REDUCTION METALLURGY (31)

The Reaction Between Magnetite and Ferrous Sulphide: Part II. F. S. WARTMAN & G. L. OLDRIGHT. *Bureau of Mines Report of Investigations*, 3072, Mar. 1931, 10 pages.

Silica and magnesia accelerate, whereas lime, alumina and cuprous sulphide hinder the reduction of magnetite by FeS. Orthoclase, anorthite, albite and kaolin also accelerate the reaction. AHE(31)

Lead Smelting and Zinc Fuming at Tadanac, B. C. GEORGE J. YOUNG. *Engineering & Mining Journal*, Vol. 131, May 11, 1931, pages 415–419.

The third of a series of articles on the technical operations of the Consolidated Mining & Smelting Co. of Canada, Ltd. Selective flotation has been steadily improving. The zinc plant now receives a zinc concentrate containing about 50% zinc, and a little over 3% lead, and the lead smelter a product containing 70% lead with less than 5% zinc. Zinc is recovered in the hydrometallurgical treatment and the Dwight-Lloyd sintering furnaces successfully cope with the fine lead concentrate. A flowsheet is shown, also a layout of lead blast furnaces and zinc plant. WHB(31)

Recovery of Zinc from Lead Blast Furnace Slag. RUSSELL B. CAPLES (Anaconda Copper Mining Company). *American Metal Market*, Vol. 38, Apr. 29, 1931, page 3.

Presented at Annual Convention American Zinc Inst., St. Louis, Mo., April 1931. Consists of slag treating furnace, 300 tons molten slag capacity per day. Furnace is of rectangular cross-section; sides, ends and top made of water jackets; bottom of water cooled cast iron plates resting on concrete foundation; furnace charge 35 tons. Furnace cycle 30 min. charging, 140 min. blowing and discharging, or total 2 hrs. 50 mins. per charge. Zn content of slag from furnace runs 3%. Coal consumption 30 to 40% of weight of slag treated (10,000 B. T. U. coal). Air averages 8,000 ft.^{3} free air/min., under 14 lb. pressure. DTR(31)

Flotation Tests on Converter Slag. FRANK S. WARTMAN. *Report of Investigations* No. 3068, *United States Bureau of Mines*, Apr. 1931, 7 pages.
It is possible to recover by flotation about 90% of the Cu content of a chilled converter slag containing 3% Cu and to obtain flotation concentrations containing 35% Cu. Reagents were 0.14 lb. No. 5G. N. S. pine oil/ton of slag, 0.1–0.15 lb. amyl xanthate, 1.25–3.0 lb. H_2SO_4, and 0.12–0.25 lb. P. E. oil. AHE(31)

The Recovery of Vanadium Pentoxide from Zinc Ores. *Chemical Engineering & Mining Review*, Vol. 23, Mar. 5, 1931, pages 215–216.
Vanadium pentoxide is recovered from zinc-iron-vanadate. The process developed by R. H. Stevens and employed at the Rhodesia Broken Hill Development Co., Ltd., is described. Vanadium is precipitated from the zinc solution as zinc or iron vanadate or a mixture thereof, and is filtered in pressure filter presses. After washing, the precipitate is discharged and transported to the storage-bin. It is fed from the storage bin to the grinding mill where it is made into a slurry. The mill discharge is pumped to storage tanks where it is kept agitated. Caustic soda is produced by the interaction of lime and sodium carbonate in the form of a liquor containing 75 g./l. caustic soda. This reacts completely with the vanadium in 1–2 hrs. at 100° C. The sodium vanadate solution is treated in the precipitation tank with sulphuric acid until the free acidity is about 5 g./l. sulphuric acid. Steam brings the temperature to 95° C. Excess of acid generally lowers the precipitation efficiency, but may yield a purer product. Impurities remain in solution. In the filter presses the vanadium hydrate is washed to remove all soluble salts. From the bins the hydrate is fed to a gas-fired melting furnace. The oxide produced is 90–95% vanadium pentoxide and is practically free from phosphorus and sulphur. The balance consists of alkalies with small amounts of silica and iron. WHB(31)

The Preparation of Raw Materials at the Röchling Iron & Steel Works at Völklingen. (Die Aufbereitung der Rohstoffe bei den Röchlingschen Eisen- und Stahlwerken, A.-G., in Völklingen.) A. WAGNER. *Stahl und Eisen*, Vol. 51, Feb. 19, 1931, pages 217–225.
Report 117 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. The article gives a detailed illustrated description of the raw materials dressing plant of the Röchling Steel Works, including ore crushing plant, ore screening plant and ore sintering plant. The economies are considered. By certain technical changes of the coal washing plant, it has been possible to decrease materially the ash content of the coal thus improving the quality of the coke made. GN(31)

Thin-Walled Blast Furnaces. JIDRICH SAREK. *Rolling Mill Journal*, Vol. 4, Oct. 1930, pages 515–518; *Iron Age*, Vol. 126, Dec. 11, 1930, pages 1770–1771.
From a paper read before the Iron & Steel Institute, Oct. 5, 1930. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 20. MS + VSP(31)

Gas Flow in Blast Furnaces. *Iron & Coal Trades Review*, Vol. 120, Feb. 2, 1930, page 318.
Abstract of *United States Bureau of Mines, Report of Investigation* 2978, by S. P. Kinney. This report covers part of the material given in United States Bureau of Mines Technical Paper 442 by the same author. See *Metals & Alloys*, Vol. 1, May 1930, page 528. RHP(31)

Prolong Iron Ore Resources by Beneficiation. *Iron Age*, Vol. 126, Dec. 25, 1931, pages 1927–1929.
Taken from discussion at the annual meeting of the Iron & Steel Division of the American Institute of Mining and Metallurgical Engineers held during the National Metal Congress. Ores of indeterminate value and some which were worthless are being successfully treated. Probable life of Lake Superior iron ore is about 30 yrs. Low grade ores may be treated, first by reducing to metallic state, crushing to suitable size and concentrating magnetically. High grade ores to be used in electric or open-hearth furnace and the low grade in the blast furnace. VSP(31)

The Iron Ore Deposits of South Africa. (Die Eisenerz-Lagerstätten Südafrikas.) H. SCHNEIDERHÖHN. *Archiv für Eisenhüttenwesen*, Vol. 4, Dec. 1930, pages 269–276; *Stahl und Eisen*, Vol. 51, Jan. 15, 1931, pages 68–70.
Report 25 of the Ore Committee of the Verein deutscher Eisenhüttenleute. According to the general classification of the origin of ore deposits, the ore deposits of South Africa have been studied. There are found to be deposits of magmatic, sedimentary and metamorphic origin. The amount of the deposits and the average composition of the ores is given. Some of the magmatic deposits contain between 2% and 20% TiO_2. An export of the South African ores does not seem to be economical, but a home iron industry can be based on these deposits. English and German capital is at present building a steel mill near Pretoria. GN(31)

Fine Chemicals as Precious Metal Precipitants. E. T. ELLIS. *Metal Industry*, London, Vol. 38, Apr. 10, 1931, pages 377–378.
Among the chemicals used to precipitate metallic gold from acid solutions of gold nitrate and chloride are ammonium potassium and sodium oxalates. Antimony trichloride, ferrous sulphate and stannous chloride precipitate metallic gold from chloride solutions. Magnesia, potassium hydroxide and zinc oxide precipitate the oxide from chloride solutions, and potassium cyanide precipitates the cyanide. PRK(31)

Graphical Carbon Balance of the Blast Furnace. T. J. ESS (Republic Steel Corp.). *Iron & Steel Engineer*, Vol. 8, Apr. 1931, pages 173–176.
The author proposes a graphical method of obtaining a carbon balance on the blast furnace. WLC(31)

Progress in the Flash Roasting of Sulphide Ores. HORACE FREEMAN. *Canadian Mining & Metallurgical Bulletin* No. 230, June 1931, pages 715–725.
Flotation pyrite containing 2 to 3% moisture and about 50% of S, or lump pyrite ground in a ball mill, is burned in a special furnace. Operating data are given. Steam is raised with the hot gases (1 lb. per lb. pyrite), the sinter (65% Fe) is used for sponge iron, and SO_2 is available for use. AHE(31)

Reduction of Zinc Oxide by Methane or Natural Gas. H. A. DOERNER (U. S. Bureau of Mines). *American Metal Market*, Vol. 38, Apr. 30, 1931, pages 3, 5, 10.
Reprinted from U. S. Bureau of Mines Report of Investigations 3091. Thorough study of this process. DTR(31)

Modern Blast-Furnace Practice. JAMES R. YOUNG & R. C. IRVING. *Proceedings Australasian Institute of Mining & Metallurgy*, No. 79, Sept. 30, 1930, pages 215–57.
Modern developments are more in the nature of refinements than in changes of a radical nature. The tendency is to have bigger furnaces, particularly in the hearth, with steeper boshes. There is a steady increase in stock-line diameters and an increase in stock-line areas compared with the large bell. This is to reduce the velocity of the top gases and so minimize dust losses. AHE(31)

The Production and Supply of Foundry Pig-Iron. *Foundry Trade Journal*, Vol. 44, Apr. 23, 1931, pages 294–296.
Report of paper by H. G. Scott on the blast furnace, its limitations, and its relations to the cupola, together with a discussion of the paper. OWE(31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

The Development of an Enamel on a Eutectic Basis. HAROLD E. SIMPSON. *Enamelist*, Vol. 4, Jan. 1931, pages 28–46, 54–55.
Object of investigation was to develop a eutectic solvent for an enamel by the combination of several eutectics, then to add silica to increase the refractoriness of the enamel up to the limit of its capability to dissolve silica without endangering its bond to the metal body. Study of eutectic composition of the $RO-B_2O_3-SiO_2$ systems. The $Na_2O-B_2O_3-SiO_2$, $K_2O-B_2O_3-SiO_2$ and $PbO-B_2O_3-SiO_2$ deformation eutectics being known, a knowledge of the $CaO-B_2O_3-SiO_2$ system was necessary. A study of the high B_2O_3 area of this system was made at approximately 4% intervals. A member high in CaO and SiO_2 and which on repeated fusions showed practically 100% glass was selected as a practical member to blend with the $Na_2O-B_2O_3-SiO_2$ and the $PbO-B_2O_3-SiO_2$ eutectic to form a eutectic solvent. Combinations of these eutectics and the $CaO-B_2O_3-SiO_2$ mixture were made and applied to cast iron by the dry process. Additions of SiO_2 were also made to these enamels up to 1.5 molecular equivalents. The physical properties of these enamels, such as brilliance, smoothness, texture, bonding power, resistance to acid attack, etc., were determined. MFB(32)

Moisture Expansion of Glazes and Other Ceramic Finishes. H. G. SCHURECHT & G. R. POLE. *Bureau of Standards Journal of Research*, Vol. 6, Mar. 1931, pages 457–463.
Research for ascertaining why some glazes are more resistant to "moisture crazing" than others revealed the fact that certain glazes expand, because of the action of water, similarly to some of the ceramic bodies to which they are applied. Although a control of this type of expansion is very important in fitting glazes to bodies, it has not been previously considered. Its importance should be evident at once when it is considered that a large "moisture expansion" in a glaze, or other finish, is in many cases an indication that the glaze will not be so liable to craze when the ceramic ware of material on which it is used is exposed to moisture. This follows since the glaze and the body on which it goes and which is ordinarily very susceptible to this kind of expansion will then increase in size simultaneously and more nearly at the same rate. Such conditions lessen the tendency of the body expansion to cause tensile stresses in the glaze. In this investigation specimens of various finishes were subjected to steam at 150 lbs./in.^{2} for an hour because it was known that this treatment of such materials produces similar effects to those caused by long exposure to weather. This artificial weathering treatment caused in lustrous glazes an average expansion of 0.004%, in mat glazes 0.011%, in vitreous slip finishes 0.005%, and in porous slip finishes 0.033%. The moisture expansion of one of the mat glazes was 30% of the average obtained for a ceramic body having an absorption of approximately 12%. This proclivity of ceramic finishes to expand by the absorption of moisture can be controlled in their manufacture. (32)

Soil Pipe Coated, Wrapped Mechanically in Plant. *Steel*, Vol. 87, Sept. 25, 1930, pages 57, 60.
Describes machine developed by the Hill, Hubbell & Co. division of the General Paint Corp. for application of coatings and wrappings at the pipe mills. Pipe is fed into the machine and rotated as it is moved forward. It is scraped, coated with a bitumen, and wrapped spirally with a layer of felt and a layer of heavy kraft paper. MS(32)

Aluminum Paints. (Aluminiumfarbe.) IV–VI. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Sept.-Oct. 1930, pages 19–32.
Aluminum paints are made of aluminum bronze and oil or linseed oil. They are now used extensively for protective coatings and as decorative paint. The various compositions are described. Standardization, tests and resistance to weather are discussed. Ha(32)

Chemical Characteristics of Cement Pipe Lining. E. L. CHAPPELL (National Tube Company). *Industrial & Engineering Chemistry*, Vol. 22, Nov. 1930, pages 1203–1206.
Presented before the Division of Industrial & Engineering Chemistry of the American Chemical Society at the September Meeting in Cincinnati, Ohio. 7 references. The data presented show that cement linings in use from 40 to 60 years have gradually lost their lime content, which has been replaced by iron hydroxide. This change is found to take place more rapidly in hot water. The replacement of lime by iron hydroxide does not result in the disintegration of the lining, nor does it appear to impair the protectiveness of the lining. Laboratory experiments show that pure silica sand in thin films greatly decreases the corrosion of cement and gradually becomes cemented into still more protective layers by the precipitation of iron hydroxide from the steel beneath. MEH(32)

Protection of Aluminum by the Lime-Method. (Aluminiumschutz nach dem Kalkverfahren.) FREITAG. *Oberflächentechnik*, Vol. 8, June 2, 1931, page 124.
Attention is called to the recently developed method of producing a grayish coating. By this method, the aluminum articles are boiled in a solution of 10 g. hydrated lime and 10 g. finely powdered gypsum for each l. of water. Ha(32)

Preparation, Use and Application of Aluminum Paint. A. C. CAMP. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, pages 701–704.
Al bronze powder is made by stamping Al into very small, thin flakes and is finished by a special polishing process which gives it a lustrous and brilliant surface. When mixed with a vehicle, the flakes come to the surface and form an almost continuous film of Al, which has much life and protective power because of its capacity to light. The powder is used with a wide variety of vehicles, the specific applications for which they are suitable being outlined. A "spar" varnish of just the proper consistency without thinning should always be used for exterior work. This type of Al paint is particularly adapted for application to metal surfaces. Amount of powder required to make a durable paint is about 20–25% by weight. MS(32)

Developments in Baked Finishes. WILLIAM J. MISKELLA. *Metal Cleaning & Finishing*, Vol. 2, July 1930, pages 627–631.
In removing oil and grease from metal surfaces, fire hazard and other objectionable features have been eliminated by the use of a cleaning compound containing a volatile solvent and an absorbent material such as Fullers' earth. A priming material made of a synthetic resin has been developed, which is not baked on until after the surface coat is applied. Discusses advantages. MS(32)

Finishing of Steel Bodied Tile. GEORGE D. HAINES (Porcelain Tile Co.). *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, pages 707–710.
Tile, formed from sheet steel and coated with vitreous enamel, is widely used for walls in the sanitary fixture industry. The steel body is blanked and formed in a progressive die, and is then cleaned, pickled, dipped in a neutralizing bath, washed and dried. The tile is given a ground coat, fired, and then the color coat is applied and fired. The ground coat has a higher fusion temperature than the color coat. Gives method of setting the tile. MS(32)

Oven Installation for Dipping and Baking Three Coats of Japan Continuously. J. B. NEALEY. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1403–1404.
Installation at plant of Hupp Motor Car Corp., Detroit, Mich. consists of 3 gas-fired japanning ovens on roof with 3 dip tanks on floor below and so arranged that a single conveyor serves both ovens and dip tanks. MS(32)

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy.

Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given.

Information about this service may be secured by writing to the Patent Department, METALS & ALLOYS, 810 Eighteenth Street, Washington, D. C.

United States Patents

Note: Numbers of Reissue Patents are preceded by "Re."

Subject of Invention, Patentee, Patent No. and Filing Date.

Manufacture of stainless iron. A. L. Feild, 1,812,941, 12/18/26, renewed 1/14/31.

Apparatus for making wheel spiders. I. H. Judd, 1,812,959, 7/23/28.

Machine for bending sheet metal shapes. A Rafter, 1,812,982, 12/13/29; 1,813,951, 12/8/28.

Method of casting metals and alloys therefor. W. C. Smith, 1,812,992, 10/12/27.

Process of refining metals. W. C. Smith, 1,812,993, 6/21/29.

Process of case hardening. R. J. Cowan, *et al.*, 1,813,028, 3/8/30.

Mold for alumino-thermic welding of rails. J. H. Deppeler, 1,813,032, 8/-23/29.

Process for the treatment of zinciferous and composite ores by the volatilization of metallic elements. A. Folliet, *et al.*, 1,813,042, 5/27/29; France 5/30/28.

Tube expander and method of expanding tubes. K. A. Stenner, 1,813,096, 8/14/29.

Rolling mill. C. White, 1,813,129, 2/25/28.

Billet conveying apparatus for heating furnaces. M. K. Nye, 1,813,195, 2/12/30.

Lead alloy. R. J. Shoemaker, 1,813,324, 11/28/28; 1,815,528, 12/2/29.

Electric arc furnace and crane structure. 1,813,397, 6/18/30.

Steel ingot. W. H. Ramage, 1,813,507, 1/24/27 (Division of application filed 1/28/26).

Ingot mold. W. H. Ramage, *et al.*, 1,813,508, 3/22/30.

Process of making ferrous products faced with stable surface alloys. P. A. E Armstrong, 1,813,654, 3/30/29.

Hot-metal-working tool. P. B. Piersol, 1,813,677, 11/10/28.

Lap welding machine. E. Bryan, 1,813,727, 11/26/28.

Treatment of metal. F. J. Crolius, *et al.*, 1,813,840, 11/12/30.

Process of producing protective metal coatings. C. G. Fink, 1,813,842, 7/-23/25.

Aluminum alloy. H. C. Hall, *et al.*, 1,813,850, 9/30/30; Great Britain 10/1/29.

Casting ladle. F. G. Carrington, 1,813,381, 6/8/28.

Method of and apparatus for soldering. D. M. Boothman, *et al.*, 1,813,657, 9/12/28.

Annealing magnetic punchings. L. E. Hildebrand, 1,813,802, 2/11/29.

Process for the production of beryllium alloys, in particular those with a high beryllium content, by means of fused liquid electrolysis. H. Fischer, 1,813,919, 5/22/29; Germany 11/13/28.

Process for the recovery of cadmium from compounds of cadmium and oxygen by distillation. C. B. von Girsewald, 1,814,023, 9/11/30; France 10/24/29.

Soldering iron. E. Jacobson, 1,814,041, 4/8/30.

Process for extracting a metal from its ore. A. Schwarz, 1,814,062, 9/19/28.

Purification of calcium. H. E. Bakken, 1,814,073, 3/10/26.

Roller type conveyer for heat treatment furnaces. R. J. Fahrenwald, 1,814,082, 1/19/29.

Centrifugal casting machine. W. H. Millspaugh, 1,814,176, 6/18/29.

Core box for ingot molds. J. E. Perry, 1,814,185, 3/28/28.

Induction heating apparatus. O. Neiss, 1,814,225, 12/5/28; Germany 12/-7/27.

Metal rolling mill screw down control. W. R. Webster, *et al.*, 1,814,354, 12/15/28.

Molding apparatus. J. T. Stoney, 1,814,416, 3/14/29 (Division of original filed 11/6/26).

Method of making electrical resistances. R. C. Benner, *et al.*, 1,814,583, 4/5/27.

Method for purifying steel. H. A. Bost, *et al.*, 1,814,584, 2/27/30.

Apparatus for controlling the shearing of moving materials. F. B. Crosby, 1,814,586, 8/1/29.

Process for widening rolled metal products. H. M. Gersman, 1,814,593, 6/21/26 (Continuation of app. filed 8/12/25).

Apparatus for widening rolled metal products. H. M. Gersman, 1,814,594. 6/21/26.

Method of preparing metal surfaces to receive permanent coatings. R. Z. Hopkins, *et al.*, 1,814,600, 12/29/28.

Method of treating ores. A. J. Koebel, 1,814,602, 3/8/28.

Ductile thorium and method of making the same. J. W. Marden, *et al.*, 1,814,-719, 6/5/24.

Preparation of ductile vanadium. J. W. Marden, *et al.*, 1,814,720, 6/6/25.

Preparation of ductile uranium. J. W. Marden, 1,814,721, 1/13/25.

Pressure distributing means for bearings. P. G. Palmgren, 1,814,734, 11/-14/25.

Rolling mill guide. P. G. Palmgren, 1,814,735 & 1,814,736, 10/17/29; Sweden 10/23/28.

Mold. E. G. Grundstrom, 1,814,797, 8/7/29.

Method and apparatus for treating slag. J. M. Hughes, *et al.*, 1,814,808, 6/3/30.

Arc welding electrode. J. M. Weed, 1,814,878, 1/13/25.

Method of soldering chains, chain-mesh or the like. G. B. Pforzheim, 1,813,-904, 3/12/28; Germany 3/17/27.

Separating volatile metals by sublimation. H. E. Bakken, 1,814,072, 1/11/26.

Process for producing metals from their oxide ores. W. E. Trent, 1,814,461, 2/28/28.

Method of and apparatus for testing metals and alloys. M. A. Miller, 1,814,-522, 1/5/29.

Core removing device. J. Hourigan, 1,814,928, 10/31/29.

Method of and means for roasting zinc blende and the like. G. Balz, 1,815,040, 10/25/28; Austria 10/31/27.

Alumino-thermic steel. J H. Deppeler, 1,815,052, 4/17/29.

Method of producing tantalum and other rare refractory metals by electrolysis of fused compounds F. H. Driggs, 1,815,054, 5/4/28.

Production of industrially valuable beryllium-bearing salts from beryllium-bearing minerals. H. Fischer, 1,815,056, 12/13/28; Germany 12/17/27.

Nonferrous alloy. (*Cu-Zn-Al-Ni.*) W. B. Price, 1,815,071, 4/16/31.

Chromium plating. E. Sohn, *et al.*, 1,815,081, 11/5/28.

Centrifugal tube-casting apparatus. I. Bignami, *et al.*, 1,815,093, 5/20/29.

Machine for bending sheet metal. R. M. Hinrich, 1,815,102, 3/17/30.

Apparatus for making pipe couplings. J. Lamond, 1,815,107, 9/12/29.

Tube expander and the like. G. Wiedeke, 1,815,174, 12/6/29.

Method of casting metals. H. L. Coles, 1,815,186, 2/20/29, renewed 1/12/31.

Safe and vault member and construction. H. L. Coles, 1,815,187, 4/24/30.

Electric soldering means. J. A. Toleik, 1,815,280, 8/1/27 (Division of application filed 1/30/26).

Bushing bearing and method of making it. J. Brincil, 1,815,344, 7/9/28.

Method for casting metals. A. W. Morris, *et al.*, 1,815,360, 2/19/29.

Apparatus for casting metal. A. W. Morris, *et al.*, 1,815,361, 11/21/29. (Division of application filed 2/19/29).

Tube piercing and expanding plug. W. Bark, 1,815,426, 12/4/29.

Plug bar for tube making machines. W. Bark, *et al.*, 1,815,427, 12/4/29.

Welding rod. F. A. Fahrenwald, 1,815,464, 1/9/29.

Zinc base alloy. (*Zn-Cu-Si.*) P. J. Morell, 1,815,479, 6/18/30.

Bright annealing of metals. R. G. Guthrie, *et al.*, 1,815,505, 11/15/29.

Rolling mill. J. J. O'Brien, 1,815,578, 8/27/29.

Hot metal mixer. L. E. Allen, 1,815,605, 6/16/28.

Process of plating metal. W. E. Watkins, 1,815,638, 5/24/29.

Furnace charging apparatus. H. D. Cook, *et al.*, 1,815,666, 11/18/30.

Method of heat treating metal. R. V. Wilson, 1,815,691, 10/31/28.

Method of and material for sealing containers. B. J. Babbitt, 1,815,695, 10/31/28.

Coiled filament and process of making it. (*Single crystal tungsten.*) F. Koref, *et al.*, 1,815,779, 6/1/22, renewed 3/23/29; Germany 7/13/21.

Die casting machine. A. S. Kipp, 1,815,776, 5/27/29.

Manufacture of finely subdivided metals. K. Marx, *et al.*, 1,815,790, 4/-14/28; Germany 7/11/27.

Rolling mill and process for rolling tubes. J. Roeder, *et al.*, 1,815,867, 6/1/28; Germany 8/20/27.

Method of producing zinc. F. R. Kemmer, 1,815,260, 6/12/29.

Method of recovering metals and oxides from boiler ash. T. F. Baily, 1,815,888, 4/2/29.

Charging bell construction. C. W. Andrews, 1,815,892, 1/20/28.

Apparatus for charging blast furnaces. A. J. Boynton, 1,815,897, 9/1/28.

Apparatus for cleaning gases. H. A. Brassert, *et al.*, 1,815,898, 1/27/28.

Method for the treatment of iron ore. H. A. Brassert, 1,815,899, 1/14/29.

Construction of hot blast stoves. H. A. Brassert, 1,815,900, 6/19/30.

Extracting of iron. A. Langer, 1,815,946, 4/6/29; Austria 4/19/28.

Portable molding machine. E. O. Beardsley, *et al.*, 1,816,000, 2/15/26; 1,816,999, 2/15/26.

Manufacture of zirconium compound refractories. G. J. Easter, 1,816,006, 5/6/29.

Refining molten metals. G. S. Evans, 1,816,007, 10/18/29.

Soldering apparatus. C. Helle, 1,816,115, 12/1/30; Germany 11/4/30.

Manufacture of iron carbonyl. A. Mittasch, 1,816,122, 2/6/26; Germany 2/9/25.

Composition for cadmium plating baths. C. H. Humphries, 1,816,152, 9/-23/27.

Blast furnace control system. R. P. Brown, 1,816,174, 4/16/28.

Flying shears. L. Johnson, 1,816,187, 4/22/26.

Method of forming resistor units. L. E. Power, 1,816,194, 6/10/27.

Welding machine. E. Riemenschneider, 1,816,231, 5/25/29.

Annealing furnace. N. G. Girshowitch, 1,816,253, 10/3/30.

Manufacture of hollow sheet metal shapes. Otto Reifurth, 1,816,298, 5/9/29; Germany 11/20/28.

Electrolytic refining of metallic aluminum. W. D. Treadwell, 1,816,304, 11/30/29; Germany 11/30/28.

Automatic feeding apparatus for sheet metal working machines. C. L. Eksergian, 1,816,319, 4/3/29.

Mold carrying conveyor. E. F. Miltenberger, 1,816,336, 2/1/30.

Method and means for forming internal flanges on tubular bodies. C. Boye, 1,816,357, 12/26/28.

Drawbench tongs. E. K. Holmes, 1,816,484, 5/24/26.

Swaging apparatus. J. A. Lewis, *et al.*, 1,816,488, 2/5/27 (Division of application filed 3/12/26).

Regenerative gas-fired open-hearth furnace. W. Schucany, 1,816,497, 8/24/26; Germany 9/1/25.

Method of treatment of non-ferrous alloys. E. M. Wise, 1,816,509, 9/3/27.

Shaping the meeting edges of curved blanks in the manufacture of sheet metal pipes and the like. W. R. Hume, 1,816,534, 6/6/28; Australia 6/27/27.

Machine for filling flasks for founding. W. F. Piper, 1,816,612, 6/7/29.

Method of galvanizing. J. L. Schueler, 1,816,617, 9/29/27.

Process for refining bismuth. W. C. Smith, *et al.*, 1,816,620, 2/6/29.

Method of producing tin. A. L. J. Queneau, 1,816,742, 1/6/28.

Permanent mold. N. J. Quinn, 1,816,744, 11/23/27.

Welded spigot and socket joint. J. Gradl, 1,816,770, 5/24/26; Germany 5/27/25.

Means for packing sand in foundry molds and cores. M. Grindal, 1,816,774, 9/10/29; Germany 10/5/28.

Prepared ingot material for use in drain opening compounds and process for making it. (*Zn-coated Al particles.*) W. C. Gangloff, 1,816,805, 6/21/28.

Checkerwork. J. P. Grilli, *et al.*, 1,815,905, 7/15/29.

Rotary casting machine. E. W. Smith, 1,816,059, 12/24/28.

Recovery of metals from ores. A. L. J. Queneau, 1,816,743, 7/26/28.

Austrian Patents

Subject of Invention, Patentee, Patent No. and Date of Beginning of Term of Patent.

Roller table for cooling beds. F. Krupp Grusonwerk Akt.-Ges., 122,910 (Addition to 105,573), 1/15/31.

Rotary melting furnace for metals and alloys. W. Buess, 122,909, 1/15/31.

Process for hardening the outer layers of cast iron. Aubert & Duval Frères, 122,931, 1/15/31.

Melting and refining cupola. P. Marx, 123,182, 1/15/31.

Alloy steel for the production of articles to be case-hardened by nitriding. F. Krupp Akt.-Ges., 122,775, 122,776 & 122,777, 8/15/28.

Process for producing low-carbon metals or alloys from their oxide ores. E. G. T. Gustafsson, 122,930, 1/15/31.

Reverberatory furnace, particularly a regenerative one. R. Warsitz, 122,934, 1/15/31.

Electric annealing furnace. Akt.-Ges. Brown, Boveri & Cie., 122,949, 1/15/31.

Two-piece chill mold for die casting. S. Junghans, 123,002, 1/15/31.

Molding device for making sand molds having undercut places. H. Hertlein, 123,186, 1/15/31.

Process for treating metals and alloys, especially copper alloys. W. Reitmeister, 122,939, 1/15/31.

Method of starting induction furnaces. J. Härdén & H. T. Tillquist, 122,936, 1/15/31.

Method and means for regulating the power factor of high-frequency induction furnaces. A. E. G. Union-Elektricitäts-Ges., 122,944, 1/15/31.

Process and apparatus for the electrolytic deposition of metals. Imperial Chemical Industries, Ltd., 122,937, 1/15/31.

Electroplating process, particularly for chromium-plating bulk goods in a rotating drum, using high-current density. Waldberg S. A., 122,952, 1/15/31.

Tank for the electrolytic deposition of metals. Imperial Chemical Industries, Ltd., 122,957, 1/15/31.

Process for the direct chromium-plating of high-carbon cast iron containing phosphorus. A. Butziger Verchromungsanlagen, 123,217, 12/15/29.

Process and apparatus for forming coatings of easily fusible metals by volatilization of the coating metal. American Machine & Foundry Co., 122,928, 1/15/31.

Process for making elongated bodies composed of a core and a closed sheath around the core. Metallges. Akt.-Ges., 122,897, 1/15/31.

Control for cutting or welding machines. Akt.-Ges. für Tiefbohrtechnik & Maschinenbau vormals Trauzl & Co., *et al.*, 122,900, 1/15/31.

Process and apparatus for arc welding with alternating current. A. E. G. Union Elektricitäts Ges., 122,917, 1/15/31.

Aluminothermically welded rail joint. Elektrothermit G. m. b. H., 122,919 & 122,920, 1/15/31.

Straightening and rolling machine. F. Ungerer, 122,906, 1/15/31.

British Patents

Note: When the date applied for differs from the date on which the application was lodged at the British Patent Office, the former date is given, followed by *.

Subject of Invention, Patentee, Patent No. and Filing Date.

Processes for heating material to medium and high temperatures with utilization of heat of condensation. E. Daub, 349,923, 11/27/29.

Joining tubes to plates. A. T. Lewis, *et al.*, 349,924, 11/28/29.

Processes and apparatus for heat-treatment of metal articles. H. Rosenberg, 349,902, 12/23/29.

Coating metallic articles with refractory material. Doherty Research Co., 350,003, 3/1/30.

Apparatus for the rapid charging of a furnace. H. Garreau, 349,918, 10/-7/29*.

Production of wires from aluminum alloys. H. Bohner, 349,978, 3/5/30.

Foundry molding machines. J. B. Neesham, 350,020, 3/8/30.

Aluminum alloy. H. C. Hall, *et al.*, 350,021 & 350,446 (Additions to 323,-353); 350,022 & 350,447 (Additions to 334,430), 3/8/30.

Lead-cable press for producing lead cables of varying sizes. Hydraulik Ges., 350,041, 4/6/29*.

Manufacture of steel. D. Colville & Sons, Ltd., *et al.*, 350,048, 3/12/30.

Chromium-plated talking-machine needles. Victor Talking Machine Co., 350,058, 3/14/30.

Electrolytic processes. Birmingham Small Arms Co., Ltd., *et al.*, 350,072, 3/18/30.

Process for the complete roasting of sulphur ores and other sulphur-containing substances. O. Saladin, 350,086, 3/21/30.

Aluminum alloy. H. C. Hall, 350,110, 4/1/30.

Recovery of molybdenum from mixtures of molybdenum or molybdenum compounds with other metals or metal compounds. I. G. Farbenindustrie Akt.-Ges., 350,135, 4/14/30.

Sheet metal blanks and method of making same. E. G. Budd Mfg. Co., 350,-245, 7/2/29*.

Fabricating and welding wide sheets of metal. E. G. Budd Mfg. Co., 350,246, 7/2/29*.

Method of treating wires and rods to be drawn with simultaneous use of trisodium phosphate lyes as neutralization means and drain oils as lubricant. R. W. Moll, *et al.*, 350,275, 11/27/29*.

Recuperative furnace constructions. Morgan Construction Co., 350,278, 7/4/30.

Welding. E. G. Budd Mfg. Co., 350,292, 8/8/29*.

Union of metal surfaces by welding. Westinghouse Lamp Co., 350,296, 7/17/29*.

Ingot molds. Valley Mould & Iron Corp., 350,302, 7/19/29*.

Apparatus for radially contracting and elongating metal cylinders. United States Pipe & Foundry Co., 350,336, 9/5/30.

Coiling metal ribbon. Griscom-Russell Co., 350,337, 10/29/29*.

Aluminium alloys and method of producing the same. Ruselite Corporation, 350,357, 4/25/30*.

Production of seamless tubes. Mannesmannröhren-Werke, 350,360, 10/5/29*.

Decomposing ores of zirconium. Deutsche Gasgluhlicht-Auerges., 350,728, 6/29/29*.

Copper-silicon-zinc alloy. Hirsch, Kupfer- und Messingwerke Akt.-Ges., 350,750, 5/27/30*.

Copper alloys. Akt.-Ges. vorm. O. Brandenburger Metallgiesserei u. Hüttenprodukte., 350,775, 7/17/29*.

Welded girders. Siemens-Schuckertwerke Akt.-Ges., 350,795, 9/11/29*.

Case-hardening furnace with charging device of worm type. H. Lindhorst, 350,812 (Addition to 330,188), 8/21/30.

Roasting and sintering pulverulent ores having a high sulphur content. Metallges. Akt.-Ges., 350,828, 9/28/29*.

Soldered connection between flat or slightly curved double walls. R. Samesreuther, 350,837, 10/8/29*.

Ingot molds. Felten & Guilleaume Carlswerk Akt.-Ges., 350,876, 12/23/29*.

Machine for welding the longitudinal seams of tapered tubes. Union Metal Mfg. Co., 350,495, 12/9/29*.

Tube manufacture. Union Metal Mfg. Co., 350,486, 12/9/29.

Proofing of iron and steel against rust. W. H. Cole, 350,420 (Addition to 289,906), 12/10/29.

Protection of iron or steel. H. Sutton, *et al.*, 350,469, 3/3/30.

Electric furnaces. British Hartford-Fairmont Syndicate, Ltd., *et al.*, 350,-474 & 350,476, 3/6/30.

Preparation of metals for use as catalysts. Soc. d'Etudes et d'Exploitation des Matierès Organiques, 350,451, 3/10/30.

Furnace tuyère grates. Erith's Engineering Co., Ltd., *et al.*, 350,530, 3/10/30.

Coated iron and steel articles and method of making the same. Parker Rust Proof Co., 350,559 & 350,560, 3/14/30 & 4/22/29.

Producing a phosphate coating on metal. Parker Rust Proof Co., 350,565, 4/29/29*.

Manufacture of ferro-nickel magnetic alloys. International Nickel Co., 350,603, 4/19/29*.

Welding rod. Stoody Co., 350,608, 4/22/30.

Process and apparatus for the reduction of pyritic ores. Patent AB. Grondal-Ramen, 350,625, 3/31/30.

Rolling processes. H. Weigel, 350,683, 5/12/30.

Process for the manufacture of steel having good machining properties. F. Borggrafe, 350,888 & 350,919, 1/10/30.

Alloy. H. Kanz, 350,889, 1/18/29*.

Rolling metal. Cold Metal Process Co., 351,079, 1/11/30*.

Machine for casting articles from molten metal. A. D. Lund, 350,905, 3/10/30.

Refractory mortars. E. Lux, 351,067, 3/25/29*.

Bars of type and like metals for feeding to the melting pots of type-casting and like machines. C. W. Hartmann, 351,103, 3/28/30.

Presser heads for apparatus for straightening sheet metal members or articles. W. Burrows, *et al.*, 350,966, 11/28/29*.

Presses for working sheet metal or the like. Marquette Tool & Mfg. Co., 351,146, 4/16/30.

Process of treating nickel-copper-bearing material. International Nickel Co., Inc., 351,150, 8/17/29*.

Electrodes for electric furnaces. Siemens Planiawerke Akt.-Ges. für Kohlefabrikate, 351,151, 8/1/29*.

Apparatus for chromium-plating small articles in quantity. E. Krause, *et al.*, 351,168, 5/5/30.

Continuous furnaces. Ugine-Infra, 351,176, 5/8/29*.

Purifying or refining non-ferrous metals or alloys. D. R. Tullis, *et al.*, 351,177, 5/8/30.

Burners for firing hot-blast stoves, furnaces, and the like, with gaseous fuel. J. E. Weyman, 351,180, 5/10/30.

Cutting tools made from sintered hard metal compositions. British Thomson-Houston Co., 351,189, 5/14/29.

Production of filaments and other bodies from rhenium. Siemens & Halske Akt.-Ges., 351,216, 6/4/30.

Method of and apparatus for upsetting the ends of tubes. Mannesmannröhren-Werke, 351,222, 3/19/30*.

Method of rolling tubes on plug rolling mills. Same patentee, 351,275, 9/13/29*.

Device suitable for use with electroplating vats, for removing sludge, small particles, and the like. G. Cooper, 351,277, 7/16/30.

Rotary kilns for burning cement, ore, etc. Vickers-Armstrong, Ltd., *et al.*, 351,283, 7/19/30.

Production of metallic magnesium from its compounds. Oesterreichische-Amerikanische-Magnesit Akt.-Ges., 351,295, 8/3/29*.

Regenerative reverberatory furnaces. O. Schweitzer, *et al.*, 351,297, 8/6/30.

Scale for determining the texture of sheet metal. A. M. Erichsen, 351,350, 10/9/29*.

Process of and apparatus for the electrolytic production of magnesium. I. G. Farbenindustrie Akt.-Ges., 351,503, 2/6/29*.

Reversing valves for regenerative furnaces. H. Crowe, 351,573, 10/18/30*.

Divided discharge channel for Martin furnaces. K. H. Moll, *et al.*, 351,506, 2/21/29*.

Protecting aluminium and aluminium alloys and/or other metals against corrosion. H. Sutton, *et al.*, 351,396, 2/22/30.

Lead alloys, more particularly for sheathings of electric cables. M. Thielers 351,449, 2/25/30.

Process and apparatus for the electrolytic production of metals, particularly magnesium. A. C. Jessup, 351,510, 2/28/30.

Guide for the mandrel rod and mandrel shaft in tube-drawing benches. Demag Akt.-Ges., *et al.*, 351,460, 2/22/30*.

Method of producing aluminum and aluminum alloys. W. Neumann, 351,524, 3/24/30.

Corrosion resisting ferrous alloy and manner of producing the same. Hall & Pickles, Ltd., *et al.*, 351,532, 3/26/30.

Method of building door arches and roofs for furnaces and the like. J. Shackleton, 351,578, 4/2/30.

Process of and apparatus for the granulation of liquid slag. Vereinigte Stahlwerke Akt.-Ges., 351,591, 4/3/30.

Storage and transportation of acetylene, more particularly for use in the autogenous working of metals. I. G. Farbenindustrie Akt.-Ges., 351,634, 4/22/30.

Reduction of metallic compounds. G. N. Kirsebom, 351,653, 5/14/29*.

Electroplating apparatus. Canning & Co., Ltd., *et al.*, 351,659, 5/9/30.

Heat treatment of cold shaped manganese steel articles. Taylor-Wharton Iron & Steel Co., 351,691, 5/23/30.

Method of shaping metallic bodies. Firth-Sterling Steel Co., 351,722, 10/-19/29*.

Method of welding. British Thomson-Houston Co., Ltd., 351,730, 6/4/29*.

Continuous copper-melting furnace. R. P. Heuer, 351,740, 6/28/30.

Apparatus for examining crystalline bodies with the aid of X-rays. N. V. Philips' Gloeilampenfabrieken, 351,744, 7/15/29.*

Method of repairing and filling up cavities, especially shrinkage holes in metal objects. Metallisator Berlin Akt.-Ges., *et al.*, 351,752, 7/7/30.

Control of motor-driven electric arc or flame cutting or welding machines. Akt.-Ges. für Tiefbohrtechnik u. Maschinenbau vorm. Trauzl & Co., *et al.*, 351,763, 7/13/29*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Manufacture of magnetic alloys. W. S. Smith, *et al.*, 312,445, 8/20/30.
Ore reduction process and apparatus. T. F. Baily, 312,447, 9/29/30
Core-molding machine. V. H. Curren, 312,471, 6/9/30.
Electric furnace. A. G. Lobley, *et al.*, 312,505, 8/8/29.
Sand milling apparatus. The Beardsley & Piper Co., 312,552, 12/1/30.
Spoke welding method and apparatus. The Budd Wheel Co., 312,557, 1/6/30.
Welding method. The Budd Wheel Co., 312,558, 4/3/30.
Process of carburizing and hardening metal articles. Deutsche Gold & Silberscheideanstalt vormals Roessler, 312,854, 7/21/30.
Metal-working blowpipe. The Dominion Oxygen Co., Ltd., 312,585, 5/-25/29.
Blowpipe. The Dominion Oxygen Co., Ltd., 321,586, 6/7/29.
Press for metal tubes or sheathings. Felten & Guilleaume Carlswerk Akt.-Ges., 312,590, 10/13/30.
Metal purification process. Kaiser-Wilhelm Institut für Eisenforschung, 312,608, 1/22/27.
Liquid fuel torch. Cutting & Welding Torch Corp., 312,616, 3/27/30.
Process for forging alloys having a magnesium base. La Soc. "Le Magnesium Industriel," 312,617, 3/26/28.
Wire drawing apparatus. The Morgan Construction Co., 312,627, 1/16/30.
Heat treatment of cold shaped manganese steel articles. The Taylor-Wharton Iron & Steel Co., 312,650, 5/12/30.
Billet & bloom grooving machine. L. C. Reis, 312,676, 8/13/30.
Electric arc welding method. J. C. Lincoln, 312,726, 12/18/29.
Method of electrically welding pipes. C. M. Thomson, 312,479, 1/22/30.
Casting machine for brake shoes. J. D. Travis, 312,751, 6/26/29.
Parting facing product for casting metals. B. F. Wallace, 312,754, 5/3/30.
Tube & rod forming machine. The American Fork & Hoe Co., 312,762, 8/16/29.
Blast furnace gas cleaning apparatus. H. A. Brassert & Co., 312,771, 10/-29/28.
Water cooled welding cable joint. The Edward G. Budd Mfg. Co., 312,776, 4/9/30.
Welding electrode. Same patentee, 312,779, 6/27/30.
Guide mechanism for welding machines. Same patentee, 312,780, 9/5/30.
Rotary furnace. The Canadian Westinghouse Co., Ltd., 312,786 & 312,787, 5/20/27.
Electric welding apparatus. Same patentee, 312,790, 8/4/30.
Pressure welding electrode. The Fansteel Products Co., Inc., 312,808, 1/17/30.
Process of producing articles made of magnesium-manganese alloys. I. G. Farbenindustrie Akt.-Ges., 312,815, 8/1/30.
Bearing metal. (*Pb-Ca-Sn-Hg-etc.*) The S & T Metal Co., 312,855, 5/-31/29.
Method of electrically welding tubular articles. The A. O. Smith Corp., 312,-861, 4/11/30.
Manufacture of electrically welded pipes. The A. O. Smith Corp., 312,862, 4/14/30.
Weldrod for electric arc welding. The A. O. Smith Corp., 312,863, 4/22/30.
Ingot mold. The Valley Mould & Iron Corp., 312,880, 7/2/30.
Method and apparatus for casting metals. The Wetherill-Morris Engineering Co., 312,885, 12/16/29.
Method and apparatus for electric welding. The Youngstown Sheet & Tube Co., 312,894, 5/7/29.
Process for recovery of base metals and salts from ores. E. A. Ashcroft, 312,928, 4/2/29.
Electric furnace charging apparatus. P. L. J. Miguet, 312,968, 3/22/29.
Welding machine. The Edward G. Budd Mfg. Co., 313,025, 7/4/30.
Metal reduction bomb. The Canadian Westinghouse Co., Ltd., 313,030, 12/29/28.
Method of carbonizing metals and alloys. Same patentee, 313,031, 12/31/28.
Production of metals from metal halides. I. G. Farbenindustrie Akt.-Ges., 313,056, 4/7/30.
Method of making steel abrasive materials. The Globe Steel Abrasive Co., 313,059, 2/10/30.
Apparatus for feeding wires through furnaces. The Niagara Wire Weaving Co., Ltd., 313,087, 2/10/30.
Aluminum alloy. (*Al-Cu-Cr-Mo-Ti.*) The Ruselite Corp., 313,104, 5/-12/30.
Process of manufacturing metallic beryllium or its alloys. Siemens & Halske Akt.-Ges., 313,109, 10/3/27.
Metal sheet rolling apparatus. The Wean Engineering Co., Inc., 313,121, 8/2/30.
Manufacture of elongated tubular articles (cast metal tubes). R. S. Waters, 313,138, 1/8/30.
Process of reducing tin, etc. E. A. Ashcroft, *et al.*, 313,413, 1/30/30.
Process of producing pure aluminum compounds (for production of aluminum metal). M. Buchner, 313,157, 2/27/29.
Device for refining and purifying metals. F. W. Corsalli, 313,161. 7/25/27.
Sintering machine. C. H. Mace, 313,196, 6/11/30.
Pack handling apparatus. The American Sheet & Tin Plate Co., 313,232 & 313,233, 1/10/30.
Hot mill catcher. Same patentee, 313,234, 1/28/31.
Production of finely divided metals. I. G. Farbenindustrie Akt.-Ges., 313,266, 4/8/30.
Continuous sheet steel normalizing furnace. F. A. Fahrenwald, 313,343, 4/12/30.
Tuyère. O. P. Wright, 313,344, 9/13/30.

Danish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for coating metallic bodies with tungsten or molybdenum "bronzes." Egyesült Izzolampa és Villamossági Részvénytársaság, 44,053, 7/21/30.
Process and apparatus for treating, particularly for coating the inner walls of hollow objects. H. J. Prins, 44,062, 1/10/30.
Magnetic material. Standard Electric A/S., 44,137, 10/4/26.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Rolling mill with grooved rolls. F. Moller, 707,613, 12/16/30.
Process for agglomerating and briquetting blast-furnace throat dust. A. Lang, 707,676, 12/6/30.
Improvements to metallic alloys. The Kinzokuzairyo Kankyujo, 707,693, 12/11/30.
Ingot turner. J. P. Kieffer, 707,967, 12/18/30.
Process and machine for filling molds and core boxes with sand. F. Rolff, 707,606, 12/16/30.
Improved process and machine for forging or stamping. Ford Motor Co., Ltd., 707,623, 11/17/30.
Process for casting metals. G. Pemetzrieder, 707,634, 11/20/30.
Machine for cleaning sheet metal prior to electric resistance-welding. P. Sourdis, 707,746, 3/20/30.
Automatic circuit breaker for metering energy supplied to an electric resistance-welding machine. S. A. des Anciens Etablissements Achard & Co., 707,940, 12/18/30.
Device for taking samples from billets, ingots, etc. United States Metals Refining Co., 707,703, 12/12/30.
Improvements to instruments for indicating temperature. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 707,937, 12/18/30.
Electrode furnaces controlled by means of a compressed fluid. S. A. Brown, Boveri & Cie., 707,595, 12/16/30.
Process for forming coatings by cathodic sputtering. M. Knoll, 707,671, 12/4/30.
Electrodes for electric furnaces. Cie. des Forges et Aciéries de la Marine et d'Homécourt, 707,729, 3/19/30.
New process for stamping plates for distillation and rectifying columns. J. B. J. Vidal, *et al.*, 707,769, 3/24/30.
Process and means for recuperation of heat in industrial thermal apparatus. Chaudronneries A. F. Smulders, 707,833, 12/15/30.
Improvements to conveyors for furnaces, etc. A. Smallwood, *et al.*, 707,851, 12/15/30.
Improvements to electric heating elements and to process for making them. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, Addition 38,754 (9th addition to 535,632 filed 5/18/21), 5/14/30.
Conveyor for sheet metal. Copperized Steel Ltd., 708,397, 12/26/30.
Improvements in the rolling of disks. Budd Wheel Co., 708,020, 12/11/30.
New light alloy. The Birmingham Aluminium Casting (1903) Co., Ltd., 708,178, 12/20/30.
Nitrided steel and process for making it. W. Kroll, 708,194, 12/22/30.
Process for making molybdenum carbonyl. I. G. Farbenindustrie Akt.-Ges., 708,379, 12/26/30.
Process for making finned tubing. A./S. per Kure Norsk Motor & Dynamofabrik, 708,005, 11/24/30.
Improvements to materials for facing sand molds for casting metals. B. F. Wallace, 708,018, 12/9/30.
Improvements to chill molds for casting pistons for internal combustion engines. The Borgo Piston Co., 708,041, 12/19/30.
Improvements in the fabrication of forged chains. Etablissements Doremieux Fils & Cie. E. Quinet, 708,067, 3/25/30.
Machine and installation for pickling. R. Joessel, *et al.*, 708,133, 4/2/30.
Improved plug for chill molds for casting pistons for internal combustion engines. The Borgo Piston Co., 708,183, 12/20/30.
Utilization of scrap metal of any nature. P. Selve, 708,243, 12/23/30.
Process for making porous or non-porous metal objects. I. G. Farbenindustrie Akt.-Ges., 708,259, 12/23/30.
Process for preventing the formation of "white rust" on zinc. Vereinigte Stahlwerke Akt.-Ges., 708,346, 12/24/30.
Improvements to vertical presses having a pivoting punch. Cie. Française des Métaux, 708,390, 12/26/30.
Improvements to the process and to the machine for making lead pipe. R. E. Roberts, 708,416, 12/27/30.
Electric welding machine. H. A. Schlatter, 708,417, 12/27/30.
Material for forming molds and cores for sand molds. O. Elmqvist, 708,455, 12/29/30.
Registering microdilatometer suitable for studying the transformations in alloys. S. A. de Commentry, Fourchambault & Decazeville, 708,109, 3/29/30.
Improvements in the fabrication of metal sheet, strip or wire. S. O. Cowper Coles, *et al.*, 708,420, 12/11/30.
Apparatus for the electrolytic deposition of metals. S. A. Waldberg, Addition 38,801 (1st addition to 702,855 filed 12/27/29), 4/8/30.
Process for the production of carbonyl compounds of molybdenum and tungsten. I. G. Farbenindustrie Akt.-Ges., 708,260, 12/23/30.
Improvements to methods of guiding machine tools using a template. Soc. la Soudure Autogène Française, 708,671, 4/3/30.
Improvements to machines and process for casting under pressure in metal molds. C. Pack, 708,754, 12/31/30.
Process for the production of metallic tungsten. I. G. Farbenindustrie Akt.-Ges., 708,595, 12/30/30.
Steel for making high-strength structural elements. Vereinigte Stahlwerke Akt.-Ges., 708,758, 12/31/30.
Improvements to alloys of aluminum and silicon. Aluminium Ltd., 708,848, 1/5/31.
Steel having a high elastic limit. Vereinigte Stahlwerke Akt.-Ges., 708,971, 1/8/31.
Process for making laminated metals by centrifugal casting. G. Pemetzrider, 708,578, 12/30/30.
Improvements to welded chains. Soc. La Soudure Autogène Française, 708, 961, 4/5/30.
Improvements to foundry molds and cores. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 708,798, 1/3/31.
Process for the simultaneous heat treatment of metal objects in several different localities. "Schmiedag" Vereinigte Gesenkschmieden Akt.-Ges., 708, 849, 1/5/31.
Method of making microscopical specimens for observing the surfaces of substances. Gunze Seishi Kabushiki Kaisha, 708,813, 1/3/31.
Improvements in electroforming. General Motors (France), 708,469, 10/6/30.
Process for recovering pure metals from alloys or metallic mixtures. Vatea Radiotechnische & Elektricitäts Akt.-Ges., 708,551, 12/29/30.
Controllable resistance heating element for electric heat-treating furnaces. E. F Russ, 708,843, 1/5/31.
Electrolytic process for cleaning wire, strip, etc. F. A. Herrmann, 708,954, 1/8/31.
Heat treating furnace. Poetter G. m. b. H., 708,486, 11/18/30.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Strip rolling mill. Engelhardt Achenbach sel. Söhne G. m. b. H., 527,389, 10/6/27.

Return guide for the rolled material passing between two adjacent roll stands. E. Behr, 527,390, 9/17/29.

Means for suspending the upper roll of rolling mills. A. Herrmann, 527,596, 11/20/29.

Roller bed with two or more adjacent runways for the rolled material. F. Krupp Grusonwerk Akt.-Ges., 527,761, 12/16/25.

Means for welding tubing. P. Schmatz, 527,610, 1/8/29.

Process for making pipes by helically winding a strip of sheet metal. California Corrugated Culvert Co., 527,391, 2/8/28.

Process for cold-squirting aluminum tubing. Süddeutsche Metallindustrie, 527,611, 11/23/28.

Process for making knives and forks. W. Stolz, 527,392, 6/13/30.

Decomposing ores containing titanium or niobium. I. G. Farbenindustrie Akt.-Ges., 527,615, 7/27/28.

Process for sintering dusty ores and metallurgical products. Vereinigte Stahlwerke Akt.-Ges., 527,773 (Addition to 472,916), 11/17/29.

Tap-hole plugging machine. E. Schiegries, 527,623, 2/4/30; 529,408, 2/-6/30.

Method of operating an electric steel furnace plant comprising two furnaces of different capacities. H. Röchling & W. Rodenhauser, 527,763, 1/17/26.

Process for removing a metallic deposit. Radio-Röhren Laboratorium Dr. Nickel G. m. b. H., 527,491, 9/10/24.

Electric resistance furnace whose resistance elements are held in bushings, Porzellanfabrik Ph. Rosenthal & Co. Akt.-Ges., 527,727, 11/29/28.

Method of controlling the motion of metal baths in ironless induction furnaces, Hirsch, Kupfer und Messingwerke Akt.-Ges., 527,452, 2/25/28.

Cupola forehearth. F. Schinke, 527,455, 7/31/29.

Cylindrical rotary drum furnace for melting metals and alloys. Badische Maschinenfabrik & Eisengiesserei vorm. G. Sebold u. Sebold & Neff. 527,732 (Addition to 520,174), 4/8/27.

Method and heating device for drying foundry molds. Allgemeine Elektricitäts Gesellschaft, 527,408, 9/26/30.

Device for preventing burning accidents at the interchangeable tuyères of shaft melting furnaces. R. Stotz, 527,571, 7/24/30.

Core binder. A. Stahn, 527,530, 1/12/28.

Process for making iron castings by the centrifugal method. Cie. Générale des Conduites d'Eau, 527,531, 11/13/24.

Shaking device with sieve frames, especially for foundries. V. J. Davis, 527,-572, 9/6/29.

Device for cleaning castings, using a freely movable jet of water. Badische Maschinenfabrik & Eisengiesserei vormals G. Sebold u. Sebold & Neff., 527,802 (Addition to 523,342), 2/25/27; 529,053, 4/15/27.

Production of solid lumps of metallic arsenic. W. Schärfe, 527,807, 12/23/28.

Crucible composed of conducting material, preferably graphite, to be used as bath container and as anode in fusion electrolysis. Siemens & Halske Akt.-Ges., 527,411, 3/15/29.

Process for the electrolytic deposition of heavy metals. M. Schlötter, 527,739, 11/10/28.

Process for making optical metal mirrors having high reflectivity. I. G. Farbenindustrie Akt.-Ges., 527,578, 4/28/29.

Bearing. E. Fitscher G. m. b. H., 527,744, 2/19/30.

Process for coating the inner walls of hollow sheet metal bodies with a rust-preventing metal. F. E. Krauss, 527,653, 5/29/30.

Machine for cutting moving material. Steel & Tubes, Inc., 527,424, 6/10/28; U. S. 6/10/27 & 4/21/28.

Machine for making bronze powder. Hartstoff-Metall Akt.-Ges. (Hametag), 527,536, 2/12/30.

Rolling mill having means for adjusting the pass. Engelhardt Achenbach sel. Söhne G. m. b. H., 527,856, 10/12/27.

Roller bed with individually electrically driven rollers. F. Krupp Grusonwerk Akt.-Ges., 528,036 (Addition to 512,123), 7/13/29.

Means for suspending the roof lining blocks of metallurgical melting furnaces. Wild-Barfield Electric Furnaces, Ltd., 528,276, 2/22/29; Great Britain 11/21/28.

Induction furnace for melting, annealing, hardening, etc. C. Lorenz Akt.-Ges., 527,946, 10/26/28.

Blast ducts for cupolas. F. Schinke, 528,066, 9/18/30.

Water-soluble core binder. A. Stahn, 528,172, 3/26/29.

Guide bolts for molding flasks. W. Stock, sen., 528,173, 9/6/29.

Process for making iron rolls. Gewerkschaft Kronprinz, 528,174 (Addition to 506,194), 4/17/30.

Process for improving a bearing metal alloy in which graphite or a similar ingredient is embedded. H. Borofski, 528,127, 1/4/27.

Process for corrosion-proofing aluminum-magnesium alloys containing about 10% magnesium. K. Schmidt, G. m. b. H., 528,025, 1/8/25.

Instrument for determining the change in length of test specimens. A. J. Amsler, 527,893, 3/24/29.

Electrolytic process for making anodes for electrolytic nickel-plating. Sächsische Blaufarbenwerke Verein, 527,827, 4/15/27.

Process for coating hollow surgical needles with chromium. Hessmer & Wercker, 527,903, 2/23/29.

Machine for dividing ingots. Hydraulik G. m. b. H., 527,988, 12/17/29.

Mounting for the table rollers of blooming and plate mills. Schloemann Akt.-Ges., 528,811, 8/19/30.

Method of removing the end of the billet from extrusion presses. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 528,671, 10/14/28.

Extrusion press for tubing. Hydraulik G. m. b. H., *et al.*, 528,672, 7/25/29.

Lead-cable press for making cables of different diameters. W. T. Henley's Telegraph Works Co., Ltd., 528,673, 4/12/29; Great Britain 6/28/28.

Process for manufacturing pipe connections. O. Reifurth, 528,674 (Addition to 495,952), 1/8/30.

Process for making corrugated sheets with accurately spaced corrugations. H. Syrowy, 528,487, 5/19/29.

Method of changing the shape of a hollow body by application of hydraulic pressure. United States Cast Iron Pipe & Foundry Co., 528,488, 6/26/29; U. S. 12/29/28.

Process for making very pure iron powder. I. G. Farbenindustrie Akt.-Ges., 528,463, 9/11/27.

Sand trough for sealing the throat closure against the shaft of blast furnaces. Kölsch-Fölzer-Werke Akt.-Ges., 528,828, 7/6/30.

Process for reducing iron ore with gases. I. G. Farbenindustrie Akt.-Ges., 528,346, 4/12/25.

Process for producing iron from ores, slag or other ferrous materials. E. Diepschlag, 528,678 (Addition to 470,015), 7/20/29.

Hand lever for opening and closing the doors of metallurgical furnaces. F. Krupp Akt.-Ges., 528,745, 7/23/30.

Auxiliary nickel alloy containing carbon and silicon, for the production of iron alloys containing nickel. The International Nickel Co., Inc., 528,746, 9/10/26.

Conductor for the coils of induction furnaces. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 528,690, 2/28/30.

High-frequency induction furnace for heating and melting charges of large transverse dimensions and small height. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 528,800, 7/18/29; U. S. 8/2/28.

Electric spot-welding machine. Edward G. Budd Mfg. Co., 528,605 (Addition to 499,349), 8/8/26; U. S. 8/15/25.

Device for blowing out foundry molds. W. Schwarz, 528,663, 12/20/29.

Process and device for making foundry molds. E. Moussiaux, 528,389, 5/-31/29.

Device for blowing out foundry molds with compressed air. W. Schwarz, 528,802, 12/20/29.

Die casting process and means for working it, using a low-pressure and a high-pressure blower. P. Mabieu, 528,388, 1/14/30, 12/7/29.

Process and means for improving and refining molten metals and alloys by shaking. F. W. Corsalli, 528,390 (Addition to 459,299), 7/1/26.

Device for refining or degasifying molten metals, especially iron, by jolting. C. Dechesne, 528,756 (Addition to 521,528), 6/20/25.

Removable partition for chill molds for compound casting. Vereinigte Stahlwerke Akt.-Ges., 528,524, 6/23/29.

Centrifugal casting mold for making annular castings. W. Bremicker, 528,391, 3/24/29.

Casting machine, using a centrifugal plate rotating in a stationary housing. G. Pemetzrieder, 528,392 (Addition to 525,225), 6/11/30.

Pouring trough, particularly for filling centrifugal casting molds. Cie. Générale des Conduites d'Eau, 528,525, 3/6/29; Belgium 3/6/28.

Process for annealing metal strip. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 528,615, 4/16/29.

Process for coating non-conducting objects with metallic coatings. U. Gottesmann, 528,766, 10/15/29.

Metal-cleaning and degreasing installation. M. Heller, 528,624, 2/8/30.

Adjusting device for roll housings. Schloemann Akt.-Ges., 529,128, 6/26/30.

Control valve for hydraulic presses. F. Krupp Grusonwerk Akt.-Ges., 528,889, 2/15/29.

Disk-rolling machine. Budd Wheel Co., 529,061 (Addition to 504,111), 5/14/25; U. S. 4/9/25.

Process for producing sponge iron from iron ores. F. Krupp Akt.-Ges., 529,-136, 10/12/28.

Process for preparing scrap metal for melting in electric furnaces, by removing the adhering oil. The Timken Roller Bearing Co., 529,074, 10/9/29.

Vertical electric bright-annealing furnace. Heraeus-Vacuumschmelze-Akt.-Ges., 529,194 (Addition to 480,691), 12/16/24.

Process for making magnetic materials having high permeability. Siemens & Halske Akt.-Ges., 529,241, 1/17/28.

Means for heating conducting crucibles, or metals in non-conducting crucibles by means of alternating current of any desired frequency. K. Fischer, 528,837, 3/4/30.

Method of cooling the inductor windings of electric induction furnaces. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 529,243, 7/13/30; U. S. 7/13/29.

Metal-armored, continuous carbon electrode for electric furnaces. J. Rees, 529,118, 6/6/25.

Process for making self-baking continuous electrodes. Det Norske A/S for Elektrokemisk Industri, 529,244, 9/27/28.

Scraper having two mutually insulated blades, for the welding-roller grooves o tube-welding machines. F. Stiehl, 529,119, 2/5/30.

Method of controlling the flame length in the hearth chambers of regenerative furnaces. H. Passauer, 529,144, 2/16/29.

Flask pins. L. F. Komm.-Ges., 529,153, 11/2/30.

Channel stone for conducting molten metal. Krämer & Co., 529,154, 2/22/30.

Process for the simultaneous production of two or more castings by the centrifugal method. G. Pemetzrieder, 528,881, 12/4/29.

Invar mold for casting pure metals or alloys, especially zinc and aluminum alloys. Felten & Guilleaume Carlswerk Akt.-Ges., 528,841, 12/24/29.

Process and mold for casting metals and alloys. Heraeus Vacuumschmelze Akt.-Ges., 528,882, 12/2/27.

Process for joining a metal object to a more refractory metal. Metallges. Akt.-Ges., *et al.*, 529,052, 6/23/25.

Process for making metal packing rings in one or several pieces. F. Bering, 529,253, 6/26/29.

Preparation of slimy ores for blast-roasting, and blast-roasting apparatus. Metallges. Akt.-Ges., 528,846, 6/29/29.

Production of volatilizable metals from ores, metallurgical products and residues of all kinds. F. Krupp Grusonwerk Akt.-Ges., 529,028 (Addition to 473,016), 11/6/25.

Production of metallic magnesium by reduction of magnesium compounds with carbon in the electric arc. Oesterreichische-Amerikanische-Magnesit Akt.-Ges., 529,160, 8/18/29; Austria 8/3/29.

Removal of zinc from metals and alloys, particularly from type metal. F Schweitzer, 528,927, 1/25/29.

Process for making goods similar to doublé wares. E. G. Bek, 528,885, 12/-12/24.

Process and device for making doublé and sheathed wires. Fr. Kammerer Akt.-Ges., 529,033, 4/6/30.

Roller bed or table particularly for rolling mills. F. Krupp Grusonwerk Akt.-Ges., 529,614, 2/22/30.

Welding machine for pipe elements. Vereinigte Stahlwerke Akt.-Ges., 529,-534, 4/12/28.

Process for making knife blades. Klöckner Werke Akt.-Ges., 529,799, 5/-26/29.

Method of protecting devices made of copper and copper alloys against corrosion by carboxylic acids. Soc. Chimique des Usines du Rhone, 529,693, 2/5/27.

High-frequency induction furnace. Siemens & Halske Akt.-Ges., 529,394 (Addition to 507,556), 12/9/27.

Means for regulating electric arc furnaces. Allgemeine Elektricitäts Ges., 529,307, 2/18/28.

Method of heating metal rings. Siemens-Schuckertwerke Akt.-Ges., 529,694, 8/24/26.

Process and means for making bimetallic ingots. Metallges. Akt.-Ges., 529,-350, 5/12/29.

Casting process for aluminum alloys. V. Fuss, 529,468, 5/18/29.

Device for loosening and moving the bottom plate of chill molds. Heraeus Vacuumschmelze Akt.-Ges. & W. Rohn, 529,496, 10/13/29.

Norwegian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Electric furnace. E. Bornand & H. A. Schlaepfer, 49,293, 11/19/28.

Electric furnace. A/S Moss Glasvaerk, 49,294, 12/31/28.

Process and machine for the centrifugal casting of metal ingots in rotating vertical chill molds. Mannesmannröhren-Werke Akt.-Ges., 49,297, 8/25/28.

Process for casting magnesium and its alloys in sand molds. I. G. Farbenindustrie Akt.-Ges., 49,298, 7/30/29.

Welding magnesium and its alloys. Same patentee, 49,305, 3/22/30.

Process for making welding wire. Vereinigte Stahlwerke Akt.-Ges., 49,329, 8/5/30.

Process and device for melting easily fusible alloys. C. Brackelsberg, 49,369, 11/6/29.

Fusion electrolysis process. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 49,373, 7/11/29.

Swedish Patents

Subject of Invention, Patentee, Patent No. and Filing Date:

Apparatus for the electrolytic production of light metals. Ges. für Chemische Industrie in Basel, 72,308, 7/22/30; Priority Dates 8/23/29 & 8/29/29.

Draw bench for hot-drawing seamless tubing. Rheinische-Metallwaaren u. Maschinenfabrik, 72,333, 7/29/30.

Die-casting machine. J. Polak, 72,348, 5/16/27.

Process for welding magnesium and magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 72,359, 4/29/29; Priority Date 6/12/28.

Process for producing pure iron. H. J. van Royen, 72,375, 12/6/27; Priority Dates 12/14/26 & 12/15/26.

Electric induction furnace not having an iron core. Allmänna Svenska Elektriska AB, 72,384, 11/30/28.

Protective device for electric furnaces. L. W. Wild, *et al.*, 72,385, 9/13/29; Priority Date 3/20/29.

White metal alloy. C. Philippossian, 72,395, 11/2/29; Priority Date 11/-3/28.

Process for soldering metal parts. N. V. Philips Gloeilampenfabrieken, 72,-408, 2/26/30; Priority Date 4/27/29.

Welding burner for highly explosive gas mixtures. "L'Air Liquide" S. A., 72,421, 1/20/30; Priority Date 2/8/29.

Process for producing metals. E. A. A. Grönwall, *et al.*, 72,433, 5/23/28.

Method of casting pipes in rotating molds. Sand Spun Patents Corp., 72,447, 9/2/25.

Device for stripping hollow patterns or castings from sand molds. C. B. Pike, 72,448, 12/28/28.

Cooling means for bright-annealing furnaces. Siemens-Schuckertwerke Akt.-Ges., 72,542, 11/5/28; Priority Date 3/26/28.

Electric annealing furnace. Same patentee, 72,555, 4/8/27; Priority Date 5/3/26.

Regulating device for inductive heating elements. H. Bollmann, *et al.*, 72,556, 11/22/28; Priority Date 12/7/27.

Swiss Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Tilting furnace. Siemens & Halske Akt.-Ges., 145,737, 1/8/30; Germany 1/19/29.

Joining electric furnace electrodes. Siemens Planiawerke Akt.-Ges. für Kohlefabrikate, 145,787, 4/11/30; Germany 8/1/29.

Process for producing aluminum. A. Pacz, 146,044, 12/31/28; Germany 1/7/28.

Process and machine for making welded tubing, especially precision tubing. Ges. der Ludw. v. Roll'schen Eisenwerke, 146,047, 1/25/30; Austria 2/1/29.

Device for hardening the flanks of screw and worm threads. F. Klopp, 146,049, 3/4/30.

Method and device for hardening moldboards for ploughs. Gebr. Ott, 146,050, 4/11/30.

Pipe-cutting burner. Carba Akt.-Ges., 146,110, 3/11/30.

Process for refining metals and alloys by the thermal method. Siemens & Halske Akt.-Ges., 146,311, 12/23/29; Czechoslovakia 12/27/28.

Foundry mold and process for making it. J. Durand, 146,312, 12/21/29; France 9/29/28.

Method and means for operating several equalized-pressure welding burners. F. Mangiameli, 146,313, 2/21/30.

Process and machine for making hollow bodies by welding together the two parts thereof. Budd Wheel Co., 146,314, 1/23/30; U. S. 1/26/29.

Process for making straight-walled pipe. G. A. Ferrand, 146,315, 1/2/30; France 2/1/29.

Process for making constructional elements which are to be highly stressed. Vereinigte Stahlwerke Akt.-Ges., 146,318, 3/22/30; Germany 5/17/29.

Process for bright-annealing metal objects, with exclusion of air. Akt.-Ges. Brown, Boveri & Cie., 146,319, 4/10/30; Germany 4/25/29.

Means for cooling metals under approximately constant pressure. Siemens-Schuckertwerke Akt.-Ges., 146,450 (Addition to 140,184), 8/1/29; Germany 11/15/28.

Process for protecting aluminum and its alloys against corrosion. Soc. Continentale Parker, 146,565, 11/9/29; France 11/10/28.

Process for forming an oxide layer on aluminum or aluminum alloy wires for coils. R. E. Müller, 146,566, 5/7/30; Germany 5/8/29.

Corrosion- and fire-resistant alloy steel. T. Czepl, 146,613, 6/17/30; Germany 2/6/30.

Process for making casting of an aluminum alloy having a considerable silicon content. Aluminium Industrie Akt.-Ges., 146,614, 3/11/30.

Process for producing metals by electrolysis of halide salt melts. I. G. Farbenindustrie Akt.-Ges., 146,615, 10/8/29; Germany 11/22/28, 4/26/29 & 5/1/29.

Molding machines. G. Zimmermann, 146,616, 3/10/30; Germany 3/14/29.

Jolting table. Boggild & Jacobsen, 146,617, 8/14/29; Germany 9/7/28.

Process for making castings of magnesium and magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 146,618, 11/20/29; Great Britain 12/19/28.

Two-piece die casting mold. S. Junghans, 146,619, 4/26/30.

Process for preparing coated objects, such as welding rods, electrodes, etc. La Soudure Electrique Autogène S. A., 146,620, 1/7/29; France 1/26/28.

Process for welding magnesium and its alloys. I. G. Farbenindustrie Akt.-Ges., 146,621, 3/17/30; Germany 4/26/29 & 12/14/29.

Process for welding by electric induction. E. Bornand & H. A. Schlaepfer, 146,622, 9/13/30.

Process and extrusion press for working difficultly deformable metals. P. Multhaupt, 146,623, 7/1/29; Germany 12/21/28.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

901 **Core Ovens.**—Bulletin No. 32 of the Foundry Equipment Company, Cleveland, Ohio, is devoted to their continuous conveyor core ovens. It shows a number of installations with complete descriptions, layouts and illustrations.

902 **Laboratory Furnaces.**—Catalog No. 30 of the Hevi Duty Electric Company, Milwaukee, Wisconsin, illustrates a number of their furnaces for laboratory and tool room use. They can supply almost any type of furnace or hotplate needed, including special furnaces for processes requiring higher temperatures than usual.

903 **The Brackelsberg Furnace.**—This German furnace was introduced to American foundries by the Whiting Corporation, Harvey, Ill., because they believe that it produces gray iron of higher quality than is usually obtained from present methods of manufacture. They have prepared a pamphlet which gives in great detail the physical properties of gray iron produced in the furnace, showing micrographs and giving numerous tables.

904 **Electric Furnaces.**—The Hayes "Certain Curtain" electric furnace was developed in 1926 to fill the demand for a positive furnace atmosphere control. It is designed for heat treating at temperatures between 1850 and 2500° F. A pamphlet which describes the new principle of atmosphere control which is embodied in this furnace can be obtained from the C. I. Hayes, Inc., 129 Baker Street, Providence, R. I.

905 **Silver Solder.**—The "Handy Book of Silver Solder" has been compiled by Handy & Harman, 57 William St., New York, N. Y., to present the results of tests the company has been making for the past five years. They have created a number of standard compositions which are listed in this book together with their description and prices. The same company has also issued two bulletins—No. 1, entitled "How to Use Handy Silver Solders" and No. 2 which describes their refining headquarters.

906 **Cutting Metals.**—Ramet—tantalum carbide—closely approaches the diamond in hardness, has a tensile strength of 250,000 lbs./in.^{2} and withstands shock and impact remarkably well and can be ground to a fine cutting edge. The Fansteel Products Company, North Chicago, Illinois, has issued an attractive leaflet describing this product which is offered in a wide range of styles and sizes which will be found adaptable to most turning operations.

907 **Heat Treating Furnaces.**—Bulletin No. O-3 of the Ryan, Scully & Co., Philadelphia, Pa., describes a type of oil-fired heat treating furnace which meets industrial requirements and contains unusual features with reference to rugged construction, ease of operation, control of temperature and over-all low cost of upkeep. Their bulletin No. 11 describes their portable box type high temperature electric heating furnaces for heat treating, forming, forging, etc. Bulletin No. 14 discusses their electric tempering baths for oil or salt bath mixtures.

908 **Ovens.**—Catalog No. 100 of Lydon Bros., Jersey City, N. J., lists and describes their various types of ovens, from the small laboratory oven which is electrically heated to the large gas-fired tunnel type. The catalog is well-illustrated and attractively gotten up.

909 **Nitriding.**—The Hevi Duty Electric Co., Milwaukee, Wis., has sent out their bulletin 830 which is entitled "Essentials of Successful Nitriding." It describes the process and equipment.

910 **Hardening of Steel.**—The Hump method of hardening of steel is outlined in Catalog No. 90 of the Leeds & Northrup Co., Philadelphia, Pa. In this method the hardener can see directly when the critical point of the actual tool or piece is reached, the quenching point is charted definitely above the critical, the method is more accurate than former methods, and tools or parts hardened by this method are longer-lived. The same company publishes a leaflet describing an instance where the Hump method was used and the results obtained.

911 **Stainless and Heat Resisting Steels.**—The Subsidiary Manufacturing Companies of the United States Steel Corporation are producing a comprehensive line of stainless and heat resisting steels, now available in the form of finished and semi-finished products. These alloys are all of the relatively low carbon type and may be broadly classified under two main headings: Chromium alloy steels; Chromium-nickel alloy steels. The corporation has issued a 35-page booklet describing them.

912 **Special Furnaces.**—The Surface Combustion Corporation, Toledo, Ohio, has prepared a series of leaflets discussing a number of installations of their furnaces. Each of these is a special furnace designed and built by the company. The installation is illustrated in each case and operating data are given.

913 **Furnaces for Treating Steel.**—Catalog No. 4 of the Bellevue Industrial Furnace Co., Detroit, Mich., lists and illustrates stock sizes of their furnaces and accessories designed to supply standard equipment for all methods of metal heat-treating. They are adapted for oil or for gas, or to meet individual conditions or preferences. This is an 88-page catalog and is profusely illustrated.

CONSTANCY!

THAT'S WHY A 100-FOOT INVAR TAPE ALWAYS MEASURES 100 FEET

Most metals won't "stay put" under varying conditions of heat and cold. However, Invar, a Nickel-iron alloy is a notable exception. Containing approximately 35% Nickel, it has a reputation for constancy...for exceptionally low expansibility. That's why a 100-ft. Invar surveyor's tape...in tropic sun or arctic cold...always measures a hundred feet.

Invar is a Nickel alloy with a scientific past and a bright future. Extensively used for scientific instruments, temperature regulating devices, etc., Invar is being adopted for machinery parts operating at high temperatures. When used with aluminum alloy pistons in automotive and aircraft engines, Invar overcomes excessive expansion and wear, prevents seizing, high oil consumption and allows ample clearance at all times between the piston and cylinder wall. In addition to low expansibility, Invar possesses these important mechanical properties: maximum stress, 78,500 to 85,000 p. s. i.; elongation, 40 to 45%; reduction of area, 60 to 65%.

Information concerning Nickel alloys of the Invar type will be gladly sent upon request.

Method of using INVAR for controlling expansion of non-ferrous alloy piston. Clearances between piston and cylinder wall as low as 0.003" are feasible with a 4" diameter piston.

THE INTERNATIONAL NICKEL COMPANY, INC.

Miners, refiners and rollers of Nickel. Sole producers of Monel Metal

67 WALL STREET, NEW YORK, N. Y.

● Nickel alloyed with other metals—steel, stainless steel, cast iron, brass, bronze, aluminum, etc.—insures dependable mechanical properties and one or more of the following improvements: (1) Greater impact and fatigue strength. (2) Greater resistance to heat, corrosion and wear. (3) Better workability. (4) Improved color and appearance.

Nickel ALLOYS PERFORMS BETTER LONGER

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Fifty-seven section editors and abstractors cover over 400 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstracts appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important. An improvement we hope to make in the METALLURGICAL ABSTRACTS in the near future is the cross-indexing of articles, which belong under several sections. Some of the sections are descriptive and some are self-explanatory and we have so labeled them.

CLASSIFICATIONS

0 (General). Under this heading we classify all abstracts which are of interest to the metallurgical industry in general. Compare this with Section 20—miscellaneous.

1, 2, 3 (Properties of Metals, Non-Ferrous and Ferrous Alloys). An article goes under one of these heads when the properties are emphasized and not the method of determining them.

4 (Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys). This takes articles on weather resistance, resistance to acids, etc., and protection against them.

5a (Structure of Metals & Alloys—Metallography & Macrography). An article would go in this group if it discussed the microscopic or macroscopic study of metals and alloys, or the determination of constitutional diagrams, critical points, etc.

5b (Structure of Metals & Alloys—Structure and X-Ray Analysis). This group includes articles dealing with the structure of metals and alloys as determined by X-ray analysis and X-ray examination.

6 (Physical, Mechanical & Magnetic Testing). If an article emphasizes the method of determining the properties of metals rather than the properties them-

selves it belongs in this section. The abstracts on fatigue appearing under this section are prepared with the coöperation of the Fatigue Research Committee of the American Society for Testing Materials.

7a (Electro-Chemistry—Electroplating). This will include articles on the electrolytic plating of metals.

7b (Electro-Chemistry—Electrometallurgy). This relates to the electrolytic recovery and refining of metals.

8 (Metallic Coatings Other than Electroplating). Articles on galvanizing, metal spraying or dip coating would come in this group.

9 (Industrial Uses and Applications). If the application of the metal is stressed rather than the properties the article belongs in this section.

10 (Heat Treatment). If heat treatment in general is discussed the article would be classed under section 10; if, however, any distinct operation is stressed it would go under the corresponding subhead.

11 (Joining of Metals and Alloys). The explanation for this group is similar to that for section 10.

12 (Working of Metals & Alloys). We feel that the divisions in this group are self-explanatory to men in the metals industries. We might say, though, that an article is classified under 12j (Cold Working) only when it will not fit under one of the other heads—for instance, an article on cold rolling would be put under 12c, rolling.

13 (Defects). This section includes articles dealing with inclusions, segregations, cracks, pinholes, blowholes and failures.

14 (Chemical Analysis). If the method of analysis is emphasized the article goes here.

15 (Historical & Biographical). Self-explanatory.

16 (Economic). Articles in this group are devoted to economic trends, savings, cost estimates, etc.

17 (Plants & Laboratories) This section includes descriptive articles.

18 (Machinery & Supplies). This includes descriptive articles.

19 (Bibliographies). Self-explanatory.

20 (Miscellaneous). This takes in all scattered articles which do not belong anywhere else.

21 (Laboratory Apparatus). Purely descriptive articles belong here. If results or processes are given they would go under 6 or 14.

22 (Foundry Practice & Appliances). This is self-explanatory.

23 (Furnaces & Fuels). This takes in descriptive articles. Otherwise they go under 10, heat treating, 10b, annealing, etc.

24 (Refractories & Furnace Materials). This section is hand-in-hand with 23. Furnace men should read both of them.

25 (Gases in Metals). This is self-explanatory.

26 (Inspection). This includes articles dealing with inspection, pure and simple—not X-ray or microscopic analysis.

27 (Effects of Elements on Metals and Alloys). Articles dealing with the effect of the addition of different chemical elements to metals and alloys are included in this group.

28 (Instruments & Controllers). Descriptive.

29 (Effect of Temperature on Metals and Alloys). This section is prepared in conjunction with the Joint High Temperature Committee of the A. S. T. M. and the A. S. M. E.

30 (Leaching). Self-explanatory.

31 (Reduction Metallurgy). This would include articles on blast furnace practice.

32 (Non-metallic Coatings for Metals and Alloys). Articles discussing painting, enameling, lacquering, etc., belong here.

◆ ◆ ◆ ◆ ◆

It has been our purpose in this outline to make our scheme of classification apparent to our readers and so, perhaps, make the abstract section more useful. If you have any questions pertaining in any way to the abstracts, write to us. We shall be glad to answer them in detail.

The classification number at the end of each abstract will be of assistance in mounting them on file cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

GENERAL (0)

Important Materials Used in the Manufacture of Steel for Castings. W. C. HAMILTON. *The Octagon*, Vol. 35, May 1931, page 6.
A review of the various ferro-alloys used in the manufacture of special alloyed steels, their method of production and analysis. Ha(0)

Dr. Honda Honored for Inventions. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 19, Apr. 1931, pages 88–90.
Dr. Honda writes of three matters of metallurgical interest (1) the merger of all Japanese Steel Works, (2) a dinner in honor of certain Japanse inventions given by the Emperor; one of these inventions being K. S. or Cobalt magnet steel whose properties are described, (3) quantitative measurements of austenite and martensite in quenched carbon steels and effect of tempering, shown by a curve. WLC(0)

Treatment of Stainless Steels. R. H. KASPER. *Modern Machine Shop*, Vol. 3, Apr. 1931, pages 20, 22, 24, 26, 48.
Four different kinds of steels are described as to their chemical analysis, physical properties and the heat treatment required to bring about the best results. The best manner for forging, machining, punching, forming and drawing, grinding and polishing is discussed. Ha(0)

Quicksilver. C. N. SCHUETTE. *U. S. Bureau of Mines Bulletin* 335, 1931, 168 pages.
Schuette discusses (1) prospecting, development and mining, (2) metallurgy and (3) economics of Hg. The mechanically operated furnace has largely replaced the shaft furnace. The factors influencing this change are discussed. The consumption of Hg by uses (determined by direct inquiry of consumers) is reported. AHE(0)

Committee for Aluminum and Light Metal Alloys. Designation of the Age-Hardening Phenomenon. (Ausschuss für Aluminium und Leichtmetallegierungen. Bezeichnung des Vergütungsvorganges.) G. MASING. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 35–36.
Resolution, in agreement with the Verein deutscher Eisenhüttenleute, to replace the misleading designation "Vergütung" (improvement) used in ferrous metallurgy by the designations "Ausscheidungshärtung" (Precipitation hardening) and by "Aushärtung" (hardening out). The first term will preferably be applied in scientific discussions, while the second term, lacking a clear conception and limitation, will be used in the shop. An inquiry showed that most of the members of the Committee decided on the first designation, but both designations will be used for the present. EF(0)

The Contribution of Science to the Iron and Steel Industry. ARTHUR D. LITTLE. *Yearbook American Iron & Steel Institute*, 1930, pages 45–62.
Includes discussion. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 791. (0)

The Metallurgy of the Non-Ferrous Metals. WILLIAM GOWLAND. Charles Griffin & Co., Ltd., London, 1930. Cloth, 6½ × 9 inches, 633 pages. Price $15.00.
It is becoming increasingly difficult to compress the important facts in any broad metallurgical field into a single volume.
To be up-to-date in every branch of a broad field is more than can be expected from any author. General metallurgical textbooks dealing with principles, rather than processes and plant equipment, do not become outmoded so rapidly as those which tell chiefly what industry is doing. The latter class soon tend to become of greater historical than metallurgical value. Gowland's Non-Ferrous Metallurgy, was, however, so well done that it long held its position as a standard reference book. But even this is trending toward greater historical than present-day value.
The revision of Gowland for the fourth edition is stated in the preface to differ from the previous edition chiefly in changes in the sections on refractories (mostly from Sosman's monograph on silica), copper, platinum, cadmium, tin and aluminum. That on mercury might well have been rewritten also to include reference to the work of Duschak.
The section on electrolytic zinc also fails to give the reader much insight into modern practice.
If we look at the chapter on aluminum which, Bannister states, "has been largely rewritten in view of the advancement made in the metallurgy of this metal" as a sample, we find 15 pages containing these references since 1920, with no reference to the Hoopes process, one page on duralumin, with no reference to any other heat-treatable alloy and no mention of heat-treated castings. Contrast this with 1238 pages in the two volumes of the Aluminum Industry by Edwards, Frary and Jeffries, also published in 1930. How can a University professor hope to keep up with details in a score of metallurgical industries, all growing rapidly, and revise a general reference or handbook so it becomes nearly enough up-to-date to be a satisfactory source of information? The day of such books as Gowland is passing. Instead, we need small textbooks on principles, and a whole shelf of handbooks, each one revised often by specialists, for detailed reference. No very useful purpose is served by revisions such as this fourth edition of Gowland. There is probably no better single book attempting to cover this broad subject, but the task of covering so much ground between a single pair of covers has become impossible of accomplishment.—H. W. Gillett (0)-B-

Recent Developments in Nickel Iron and Steel. CHARLES MCKNIGHT. *Yearbook American Iron & Steel Institute*, 1930, pages 195–221.
Includes discussion. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 687. (0)

Tool Steel from the Consumer's Standpoint. H. G. KESHIAN. *Metal Progress*, Vol. 20, Aug. 1931, pages 46–48.
A paper to be presented in greater detail before the Boston Convention of American Society for Steel Treating in September 1931, and to be published in the Transactions later with discussion. Lack of quantitative data on the qualities of tool steel places the designer under a serious handicap. Methods of selection of tool steel are given as (1) Tradition, (2) Personal Experience, (3) Recommendation of Steel Makers and (4) Service Tests. The first two methods of selection give the designer no quantitative guide for his work. The third as shown by quotations from catalogs of steel makers is only vaguely qualitative. Service tests are of real value as "the proof of the pudding." They, however, entail considerable expense, different operators may get different results and unnoticed changes in conditions of test result in contradictions. A quantitative numerical value for such properties as wear and shock resistance, cutting quality, shrinkage, fatigue values and other properties are to be desired. The difficulties in such determinations are numerous but their prospective value offers incentive to overcome the difficulties. WLC(0)

Brobdingnagian Bridges. OTHMAR H. AMMANN. *Technology Review*, Vol. 33, July 1931, pages 441–444, 464.
Discusses the spectacular achievements of modern bridge builders: the Hudson River (George Washington) bridge, the Sciotoville bridge over the Ohio river, Hell Gate bridge, the Kill van Kull bridge, the Quebec Cantilever bridge, Manhattan bridge and others. Discusses the feasibility of a span two miles long, with consideration to type, quality of material, erection and the possibility of making bridges beautiful as well as strong. MAB(0)

New Research Objectives—Lower Costs and Greater Consumption. ARTHUR D. LITTLE. *Chemical Markets*, Vol. 28, June 1931, pages 584–586.
An address. The economic value of research is indicated by reference to the aluminum, leather, dye, plastic and other industries. WHB(0)

PROPERTIES OF METALS (1)

The Investigation of Rhenium. (Die Erforschung des Rheniums.) OTTO HUPPERT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 23, 1931, page 666.
The 75th element of the periodic system was discovered in platinum ores in 1925 by X-ray spectrographic methods. It was named Rhenium (Re) while element 43, also unknown before that date, was found simultaneously and called Masurium. Rhenium belongs to the group of manganese and, today, can be produced in any quantity at a price of about $3.50/g. Rhenium metal is a deep black powder of high volume; its melting point has been determined as 3440° C. (a little lower than for W). Mechanically, it differs widely from tungsten. In the sintered state, it is rather brittle; but heated, it can be forged and rolled; a wire is flexible as copper wire. A rhenium wire with a core of tungsten of 0.030 mm. diameter showed a tensile strength of 50.6 kg./mm.² The crystal lattice shows a hexagonal structure. Atomic weight is 186.31; density, 20.53; measurements of electric conductivity gave a specific resistance twice as high as W. Rhenium colors the Bunsen flame a pale green; it has some characteristic bands in the green range of the spectrum. The technical applicability of the new metal is being investigated at present. Ha(1)

Electrical Resistivity of Italian Aluminum Wire. (Relazione sulle misure eseguite nel Laboratorio di Elettrochimica ed Elettrometallurgia della R. Scuola di Ingegneria di Milano sull'alluminio trafilato, crudo, prodotto in Italia.) O. SCARPA. *La Metallurgia Italiana*, Vol. 23, Feb. 1931, pages 102–105
Electrical resistivity was determined on 300 samples of aluminum wire made in Italy. The values in microhms/cc. at 20° C. ranged from 2.79 to 2.93. Only 4% were below 2.82, and only 5% above 2.89. The maximum frequency was at 2.845, the arithmetical mean 2.851. No figures are given on temperature coefficient of resistivity nor for the chemical analysis of purity. The average specific gravity was 2.705 at 20° C. The value 2.845 is stated to correspond to 60.6% of the volume conductivity of domestic copper. The samples were probably hard-drawn. HWG(1)

Iron Gives Up Its Innermost Secrets. R. L. DAVIDSON. *The Pure Iron Era*, Vol. 9, 1931, pages 16–17, 23.
Shows diffraction patterns of iron. Ha(1)

Titanium. E. P. YOUNGMAN. *Information Circular* 6365, *United States Bureau of Mines*, Oct. 1930, 39 pages.
The subject is discussed under the following headings: properties, utilization, history, ores and minerals, identification, mode of occurrence, mining and concentration, deposits, world production, domestic production, imports, exports, prices, metallic alloys, pigments, and lists of dealers. Over 40 footnote references are given. AHE(1)

Zirconium. Part I. General Information. E. P. YOUNGMAN. *Information Circular* 6455, *U. S. Bureau of Mines*, June 1931, 30 pages.
The properties, uses, occurrence, concentration, preparation, production, markets and prices, etc., of zirconium metal, its alloys and its oxide are discussed. Seven recent patents are abstracted and 25 footnote references are given. AHE(1)

The Nickel Industry. A. J. WADHAMS. *Metal Progress*, Vol. 19, March 1931, pages 92–98.
The author describes the occurrence of nickel, its recovery from the ore and the uses of its various alloys as well as those of pure nickel and its salts. WLC(1)

Note on Applications of Data on the Thermal Conductivity of Metals. M. S. VAN DUSEN (Bureau of Standards). *Preprint* for A. S. T. M.–A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 545-549.
In many thermal conductivity problems, transfer resistance is so high through a joint that attempts to increase heat flow by using a metal of higher thermal conductivity are futile. In heat transfer through a metal wall between condensing vapor on one side and a boiling liquid on the other, thermal conductivity may come in. It is also important in automotive engine design. It comes in in heating and quenching of steels, and in molds for casting. Diffusivity is the important factor, and is usually nearly proportional to conductivity. Heat capacity per unit volume is more important than specific heat. A unit volume of Al has about the same heat capacity as one of any other metal. In any problem attention should be directed to the magnitude of the various resistances to heat flow before worrying about the conductivity of any metal part. No quantitative data are included in the paper. HWG(1)

Some Series in the Extreme Ultra-Violet Spark Spectra of Copper. F. C. CHALKLIN (University of Sheffield). *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Oct. 1930, pages 711–721.
Theoretical arrangement of many of the critical potentials of copper in a series. RHP(1)

On the Plasticity of Metals. ZAY JEFFRIES. *Mechanical Engineering*, Vol. 53, Apr. 1931, pages 262–266.
Presented at the 87th meeting of the American Association for the Advancement of Science, Cleveland, Ohio, December 31, 1930. Plasticity is defined as "the quality by virtue of which a substance may undergo a permanent change in shape without rupture." Metals are crystalline, and plastic flow is the result of the movement of one position of a crystal with reference to another along crystallographic planes. Industrial metals are useful to us because of their high plasticity, without which metal-working processes could not be carried on. Some of the headings: Plastic Deformation of Single Crystals; Preferred Orientation Common in Industrial Wrought Metals; Small Loads Required to Fracture Single Crystals; Rate of Loading an Important Factor; The Wonderful Nature of Plasticity in Metals; Possibility that Free Electrons Are Essential for Metallic Plasticity; Face-Centered Cubic Metals Retain Plasticity at Very Low Temperatures. The Effect of Systematic Surface Treatment on the Photoelectric Emission from Metals. R. F. HANSTOCK. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Nov. 1930, pages 937–944.
Gives results of research on the photoelectric emission from metal surfaces in a vacuum at intervals during the process of polishing, the surface being initially in an annealed state. Materials tested were Cu, Ag, Au and Pt polished with steel and nickel. All the metals give curves of similar shape. The photoelectric current increases as the metal is changed from annealed to a polished state. RHP(1)

Heat-Treatment, Ball-Hardness, and Allotropy of Lead. F. HARGREAVES. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 149–174.
Includes discussion. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 897. (1)

On the Hardness of Electrodeposited Metals and on the Change in Hardness in Relationship to Hammering. (Ueber die Härte elektrolytisch hergestellter Metalle und die Aenderung der Härte als Funktion des Hämmerns.) GUICHARD. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, pages 205–206.
Briefly reviews a lecture delivered at the International Congress of Mining, Metallurgy and Applied Geology, Liege, June 1930. EF(1)

NEW PRODUCTS

New Sheet Metal Tester

The Wazau sheet metal tester sold by the Baldwin-Southwark Co., Philadelphia, Pa., is a deep drawing press for drawing cups (as shown in Fig. 2) from circular sheet blanks. The male die (1 in Fig. 1) of 30 mm. diameter is motor driven and the drawing force exerted by it is measured by a hydraulic capsule, indicating the load on dial 2.

Fig. 1

There are two ranges of sensitivity of 10,000 and 20,000 lbs. for the standard type of the tester, which is built in higher capacities, if desired. On the paper strips 3, a record is made of drawing force. The die 1 is attached to the upper crosshead 4, which is driven by a reversible motor, 10.

The deep drawing speed normally amounts to about 4″ per minute, but can be adjusted to other values on request.

The middle crosshead 5 carries the hold-down or blankholder, which is adjusted by hand, because it has to make small movements only. It is of particular advantage that in the Wazau sheet metal tester the pressure of the blankholder can be varied at will and measured, while in normal testers, no check of the blank holder force is possible. The blank holder loads are indicated on dial 6 and recorded on paper strip 3. Both the drawing and the hold-down force are recorded in function of the depth of draw. In this way all important variables can easily be studied and the records leave no doubt whatsoever.

The hold-down pressure is not only indicated and recorded, but can be maintained at any definite value desired, by means of a special load maintainer. This device consists of a dead weight accumulator 8 and hand pump 9. The innovation is important in that all uncertainties of tight or loose fitting of the hold-down are eliminated and the trend in practical drawing is closely imitated.

It is advisable to qualify sheets by arbitrarily selecting a certain blank diameter and drawing cups with different blank holder loads. Two things may then happen: first, failure occurs at a certain blank holder load, which thus forms a criterion, together with the initial blank diameter. If two sheets show the same qualities in this way, there may still be a difference in drawing forces permitting clear differentiation. The second case occurs when the sheet does not fail even at the highest blankholder load available. The high drawing capacity indicated hereby may then be tested by using a larger initial blank diameter and repeating the first method of test until failure occurs.

The entire procedure is autographically recorded in every step and in addition to such data as depth of draw, blank holder and drawing force, the inspection of cups drawn furnishes useful information.

Tests of this kind are recommended for testing sheet material as per the attached table that shows a series of tests on one steel in 5 different stages of treatment. No. 11 could be drawn from a blank 2.44″ diam. up to 7700 lbs. blank holder load, while No. 12 failed as soon as the blank holder load exceeded 1100 lbs. No. 13 showed almost the same behavior as No. 11, but it required higher drawing forces (see last two columns). No. 14 is better than No. 12 in that it could be drawn up to 2200 lbs. blank holder load. No. 15 is not much different from No. 12, but slightly harder to draw (higher drawing loads).

The order of materials as to drawing capacity determined from this actual series of tests is: 11, 13, 14, 12, 15. It may be mentioned that these results checked very well with practical drawing experience although no ordinary "ductility tester" could give such clear and correct discrimination.

Fig. 2.

Another method of test consists in using the same blank holder load all the time and gradually increase the blank diameter until the sheets fail. The highest diameter furnishing good cups together with the drawing force may be taken as a measure of drawing capacity.

The tester can also be used to determine the best lubricant as well as radii of fillets, clearances and so forth, in other words those factors involved in the drawing process not depending on the material itself but on the design of the drawing machine.

Sheet Tests Group 3. Samples 11–15.

Material	Thickness	Die thickness	Specimen	Sample broke		Draw finished		Deep draw. Force (Max.)	
				blank diam. inch	blank holder load (lbs.)	blank diam. inch	blank holder load (lbs.)	lbs. Load	lbs./in² Stress
No.	inch	inch	No.						
			11–1			2.44	5500	8010	53900
11	0.0382	0.0394	11–2			2.44	7700	8070	54300

			15–4			2.44	1100	6930	61800

Diam. of male die: 1.182″.

On the Wazau Sheet Metal Tester simnltaneous measurements of the following quantities are made:

Initial bank diameter.
Blankholder load.
Deep drawing load.

The first criterion is the blank diameter. Since the tester applies a male die of 1.182″ diameter, the ratio of blank diameter to die diameter gives a measure of depth of draw. The depth of draw is also indicated on the recorder paper strip and can in addition to that be measured on the finished cup.

Fig. 3 Sample of autographic record on Wazau Sheet Metal Tester (1/2 nat. size)

It is obvious from experience with other sheet metal testers that the measurement of depth of draw alone is not sufficient to discriminate between materials of different drawing quantities. For this reason, the Wazau tester permits obtaining additional information through the blank holder load.

PROPERTIES OF NON-FERROUS ALLOYS (2)

Dimensional Stability of Heat-treated Aluminium Alloys. J. D. GROGAN & D. CLAYTON. *Metal Industry*, London, Vol. 38, Apr. 10, 1931, pages 379–382.

Condensed from paper read before Institute of Metals, March 12, 1931. It was found that secular changes which occur after the normal aging process is substantially completed on "Y," Duralumin and "2L5" alloys, were negligibly small. No secular change occurred after machining aged specimens. Considerable dimensional changes occurred when material quenched in cold water was machined, but quenching "Y" and Duralumin in boiling water reduced these changes to relatively small proportions. PRK(2)

Beryllium-Containing Aluminum Alloys. (Berylliumhaltige Aluminiumlegierungen.) GEORG MASING & LISEL KOCH. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 15–24.

The wear resistance of an aluminum piston alloy with 12% Cu on a steel disc was almost doubled by the addition of 4 to 8% Be. The wear of the steel disc increased in the same amount. The tensile properties of Y alloys and piston alloys cast in sand and iron molds are influenced rather unfavorably than favorably by additions of 0.05 to 2 and 8%. The refinability of these alloys is not influenced by Be additions. Several % Be added to silumin increases the elongation if refining by sodium is applied at the same time. This is due to the favorable influence of Be on the structure by forming a ternary eutectic of about the following composition: 13% Si, 1% to 1.5% Be, the remainder Al. Tables and microphotographs are reproduced. Ha(2)

The Alloyability of Beryllium with Calcium and Magnesium. (Ueber die Legierbarkeit des Berylliums mit Calcium und Magnesium.) WILH. KROLL & ERNA JESS. *Wissenschaftliche Mitteilungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 29–32.

Microscopic examination has shown that boiling magnesium does not dissolve beryllium. In boiling calcium, however, a metallic body originates, consisting of a calcium-free core of Be and a mantle of a Ca-Be alloy of about 71% Be and 27% Ca. Under certain conditions, beryllium-containing magnesium alloys could be made, all of which showed, macroscopically as well as microscopically, numerous segregations of beryllium By diluting these high percentage alloys with Mg, other melts were obtained which also showed the beryllium segregations. All of these alloys had bad aging and mechanical properties. A table of numerical values and the thermal treatment is given. Ha(2)

Ternary Alloys of Lead. S. J. NIGHTINGALE. *British Non-Ferrous Metals Research Association, Development Report* D 3, 1929, 12 pages.

The properties of Pb alloys containing (a) 0.25% Cd and 0.5% Sb and (b) 0.25% Cd and 1.5% Sn are compared with those of pure lead as regards their utility for the manufacture of pipe. The tensile strength of the alloys is 1.62 tons/in.^{2} compared with 0.9 ton/in.^{2} for pure lead, the ductility 52–55% against 80%, and the fatigue limit 0.74–0.57 ton/in.^{2} against 0.18. The alloys are on the whole more resistant to corrosion than is lead and withstand a considerably higher bursting pressure, so that a lighter pipe can be used for the same service than is the case with lead. The working and soldering properties of the alloys are equally as good as those of lead and, taking into account their superior properties, are relatively less costly than lead. They do not undergo intercrystalline corrosion or fatigue. (2)

"Everdur," a Copper Alloy with High Mechanical Properties and Great Resistance to Corrosion. ("Everdur," lega di rame con caratteristiche meccaniche elevate a grande resistenza alla corrozione.) L. GIROLA. *La Metallurgia Italiana*, Vol. 23, May 1931, pages 383–389. 7 figures, 5 references.

General discussion of this Cu-Si-Mn alloy and its properties, as manufactured by the Società Metallurgia Italiana. HWG(2)

A New Silicon-Zinc-Copper Alloy. Parts 2 and 3. E. VADERS. *Metal Industry*, N. Y., Vol. 29, Apr. 19, 1931, pages 155–156; May 1931, pages 196–198.

Tin added to silicon-zinc-copper alloys would increase their value as bearing alloys. These alloys have same tone characteristics as bronzes for making bells. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 898. PRK(2)

A Study of Tin-Base Bearing Metals—II. G. B. KARELITZ & O. W. ELLIS. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 2, 1930, *Machine Shop Practice*, pages 87–99.

Includes discussion. The paper deals with the mechanism of wiping of babbitt linings, with certain phenomena observed during the casting of tin-base alloys, and with the effects of cold work on them. It is shown that wiping of babbitts is a result of the upper layer of the lining's reaching the solidus temperature, when the constituent with the lowest melting temperature liquefies, the babbitt becomes "mushy," and is therefore wiped by the journal. The appearance of the castings of various chemical composition is discussed, and the variation in hardness and microstructure due to cold work is given. See also *Metals & Alloys*, Vol. 1, May 1930, page 527. (2)

Elektron. *Metal Industry*, London, Vol. 38, Apr. 3, 1931, pages 356, 367.

There are two main groups of Elektron or magnesium base alloys: those weldable by oxy-acetylene flame and those not weldable. This metal can only be worked around 300° C. PRK(2)

Bearing Alloys. R. T. ROLFE. *Transactions, Manchester Association of Engineers*, 1929–30, pages 14–97. Includes discussion and 41 figs.

If lubrication always kept bearing surfaces apart, the nature of the bearing surfaces would be immaterial, but the oil film may break down and give metal to metal contact. Information as to the best alloys for use in such conditions is best obtained by making tests in the dry or only slightly lubricated condition. A bearing metal had best be hard if it is given a mathematically perfect fit. As this can seldom be approached, the usual method is to use a somewhat plastic matrix in which hard grains are embedded. This will squeeze down to a better surface. Except for small bearings, babbitt metal must be backed up by a stronger shell. Lead base alloys can be used for rather high temperatures if the heat is frictional, but in auto bearings, affected by heat from other sources than the bearing itself, the softer alloys do not serve so well. The Sn-Sb-Pb eutectic (53, 4 and 43%, respectively) melts at 177° C. and many automotive engineers object to the presence of any Pb in a Sn base babbitt. Unusual compositions, used in a vessel of the German Navy, the *Baden*, contain 1.7 to 2.3% Cu, 0.6% Pb, 3.5 to 6.5% Hg, balance Sn. The Hg is in solid solution in the tin matrix. The requirements for a babbitt are that it be readily melted, poured and machined, should have high compressive strength at working temperatures, low wear, low coefficient of friction and some plasticity. At one extreme of composition, there are no hard crystals in the matrix, at the other, the hard crystals touch each other, and crack under load instead of bending down in the matrix. Either extreme is bad, anything between may suit some service conditions. Adhesion of babbitt to gun metal, cast iron and steel was experimentally determined. Gun metal gave the same results smooth machined or rough machined. Smooth machined steel gave better adhesion than gun metal, but rough machined steel gave worse. Adhesion to machined cast iron was very poor. Comments are made on methods of lining bearings. The Pb base and the bronze bearing alloys are discussed. Annealed gun metal, free from the δ-constituent, wears readily and is not useful for bearings. Non-plastic Zn base bearing alloys have a limited use. The whole bearing should be made of the alloy as it is difficult to line shells with it. HWG(2)

PROPERTIES OF FERROUS ALLOYS (3)

Iron Chromium, Iron-Chromium-Nickel and Related Alloys. Report of A. S. T. M. Committee A-10. J. STRAUSS, Chairman. *Preprint* No. 17 for June 1931 Meeting, *American Society for Testing Materials*. 3 pages.

Atmospheric corrosion tests of these alloys, and the preparation of standard samples and methods of chemical analysis, are being considered. Cooperative acid immersion, copper sulphate stain, and salt spray tests are being carried out in 15 laboratories. Work on methods for determination of elastic and impact properties, and study of grain growth and embrittlement of low carbon plain chromium steels is contemplated, and welding is being looked into. HWG(3)

Welding of Corrosion Resisting Steels. WM. SPRARAGEN. *Welding*, Vol. 1, Nov. 1930, pages 897–900.

Discussion of the physical properties of 4 groups of alloy steel: (1) chrome irons, (2) chrome steels with over 0.2% C, (3) chrome-nickel irons with less than 0.2% C, (4) chrome-nickel steels with more than 0.2% C. Their weldability is considered and brief mention is made of certain precautions necessary in welding. Ha(3)

Steel Personality. B. F. SHEPHERD (Ingersoll-Rand Co.). *Metal Progress*, Vol. 19, Feb. 1931, pages 51–58.

A paper presented before the Western Metal Congress, San Francisco, Feb. 16, 1931, and published with discussion in the Transactions. The author defines "timbre." He shows hardening irregularities in tool steel, effect of timbre on service life, necessity for control of timbre, difference in timbre in products of several manufacturers, effect of abnormality, and that timbre exists not only in tool steel but in various alloy steels. Hardenability tests are described and discussed, illustrated by photographs. Micrographs show abnormality features of three steels. Effect of furnace practice on timbre, and variability in response to heat treatment in steels are discussed. WLC(3)

Thermodynamics of a Heat-Treated Steel. F. G. SEFING. *Michigan Engineering Experiment Station Bulletin*, No. 37, Vol. 6, May 1931, 13 pages, 9 references.

Study of storing of energy in steel during heat-treatment. Strips of 1.26% C, 0.37% Mn, 0.22% Si, 0.022% P, 0.012% S, 0.38% Cr steel were quenched from 1380° F. into water at 70° F. and tempered at 122° to 1382° F. They were dissolved in a $FeCl_3$-NH_4Cl solution in a calorimeter, without gas evolution. The undissolved residue is said to be nearly equal to the combined weight of the carbon and the Fe_3Si of the samples. No proof is adduced that Fe_3Si was in the residue. The total heat evolved in cal./g. ranged from 894 to 875. At draw temperatures up to 392° F. from 13 to 20 cal./g. more were evolved than on that annealed at 1392° F. With one specimen drawn at 350° F. slightly out of line, from 482° F. up, the excess heat evolved gradually decreased from 8 cal./g. to zero. Accuracy to 2 cal./g. is claimed. Length changes on quenched and tempered cylinders of the same steel were measured immediately and again after 10 months. The results were not especially consistent. HWG(3)

Strength of Rectangular Flat Plates under Edge Compression. LOUIS SCHUMAN & GOLDIE BLACK. *Report* No. 356, *National Advisory Committee for Aeronautics*, 24 pages.

Flat, rectangular plates of duralumin, stainless iron, Monel metal, and nickel were tested under loads applied at two opposite edges and acting in the plane of the plate. The edges parallel to the direction of loading were supported in V grooves. The plates were all 24″ long and varied in width from 4″ to 24″ by steps of 4″, and in thickness from 0.015″ to 0.095″ by steps of approximately 0.015″. There were also a few 1, 2, 3 and 6″ wide specimens. The loads were applied in the testing machine at the center of a bar which rested along the top of the plate. Load was applied until the plate failed to take any more load. The tests show that the loads carried by the plates generally reached a maximum for the 8-or 12-inch width and that there was relatively small drop in load for the greater widths. This is explained by the fact that when the plate buckles, since the greatest deflection occurs at the center, its vertical chords will shorten more there than at the ends. In consequence there will be less load on the plate at the center and more toward the ends where it is better supported to resist bending and can continue to take load after buckling has occurred. In this way, the load carried by plates of a given thickness would tend to be constant for all plates wider than that at which the maximum load is reached. Deflection and set measurements perpendicular to the plane of the plate were taken and the form of the buckle determined. The number of buckles was found to correspond in general to that predicted by the theory of buckling of a plate uniformly loaded at two opposite edges and simply supported at the edges. (3)

Some Physical Properties of Hardened Tool Steel. J. V. EMMONS (Cleveland Twist Drill Co.). *Preprint* No. 35 for June 1931 Meeting, *American Society for Testing Materials*, 30 pages, 14 references.

Torsion tests were made on specimens with 3/16″ diameter, 3″ test length on a steel of 1.12% C, 0.19% Mn, 0.30% Si, 1.07% Cr, oil quenched from 1450° to 1850° F. by 100° intervals, and drawn at 212° F. and from 350° to 750° F. at 50° intervals. The toughness (angular deformation in torsion test) varied greatly with the heat-treatment. Greatest toughness was found at 1750° F. oil 450° F. Although this gave 62.5 Rockwell C, the torsion specimen twisted through more than 360° before breaking. The "coefficient of toughness," the product of ultimate torque, in lbs. at 1 in. radius, times the angular deformation in degrees, varied from 6,000 for the highest quench and lowest draw up to 136,000 for the 1750–450° F. treatment. Other high values and the corresponding Rockwell C figures were 1550–350° F., 72,000, 62.9; 1650–350° F., 74,000, 65.6; 1650–400° F., 104,000, 63.6; 1650–450° F., 88,000, 61.4; 1750–400° F., 71,000, 63.3; 1750–450° F., 136,000, 62.5; 1750–500° F., 95,000, 59.7. Toughness is a long way from being proportional to drawing temperature as is usually assumed, nor is toughness inversely proportional to hardness. The microstructures are correlated with the mechanical tests and theoretical explanations of the phenomena discussed. The Rockwell hardness of the martensite may be explained on the basis of the size of submicroscopic particles of ferrite alone. Maximum toughness is thought to be at the point where carbide particles are in an early stage of growth and exert least resistance to slip interference, maximum strength at a later stage when they exert greatest resistance. If part of the martensite is decomposing to give carbide particles of one of these sizes and part to those of the other, great strength and toughness may be met in the same specimen. The torsion test method is advocated for determination of toughness in steels too hard and brittle for other types of test to reveal differences in toughness. HWG(3)

The Tensile Properties of Cast-Iron Sample Rods Cast Upright or Horizontally. (Ueber Festigkeitswerte von stehend und liegend gegossenen Gusseisen-Probestäben.) K. L. ZEYEN. *Krupp'sche Monatshefte*, Vol. 12, Apr. 1931, pages 57–62; *Giesserei*, Vol. 18, Feb. 27, 1931, pages 177–180.

The bend test is very often used for cast-iron because of its simplicity and cheapness. The sample rod can be cast either horizontally or vertically. Tests showed that the figures for vertically cast rods are better than those of horizontally cast rods. The tensile strength was more uniform for the vertically than for the horizontally cast rods. Some other tests corroborated the fact that additions of nickel and chromium improve the tensile strength of cast-iron. 9 references are cited. Ha(3)

High Elastic Limit Steels. Correspondence from C. H. DESCH, Sheffield, England. *Metal Progress*, Vol. 18, Nov. 1930, pages 85–86.

The writer describes certain developments in high elastic limit steel for ship building and method of test. WLC(3)

Relation between Magnetic Properties, Impact Strength and Hardness. H. STYRI (S K F Industries). *Preprint* No. 33, for June 1931 Meeting, *American Society for Testing Materials*, 12 pages.

A 1.03% C, 0.33% Mn, 0.27% Si, 1.50% Cr, 0.32% Ni steel was oil quenched at 800° to 875° C., and water quenched from 800° to 845° C. These specimens were tested, undrawn and drawn at 150°, 180° and 210° by 4 different magnetic methods, by Rockwell hardness and Charpy impact. The magnetic tests showed a fair degree of correlation with the other tests. Uniformity of heat-treatment within commercial tolerances can be checked magnetically with a reliability and accuracy equal to the usual mechanical methods of control. HWG(3)

Filling Their Niche. R. A. ZIMMERMANN. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 35–36.

Describes a few of the stainless steels made by the U. S. Steel Corporation in collaboration with the Fried. Krupp Works in Germany. Ha(3)

Steel. Report of A.S.T.M. Committee A1. J. B. YOUNG, Chairman. *Preprint* No. 9 for June 1931 Meeting, *American Society for Testing Materials*, 26 pages.

Progress reports on various committee and sub-committee activities. Changes are proposed in several specifications now reading that the steel shall be made by either or both the Bessemer or open-hearth process, to read "by one or more of the following processes, open hearth, electric furnace, or acid-bessemer." Elongation in 2″ for structural silicon steel is put at 1,600,000 divided by tensile strength. Details of boring and rough-turning for locomotive axles, shafts, and similar forgings are given. Silicon in heat-treated carbon steel helical springs is set at 0.15% minimum and the former 0.30% maximum limit removed. Comments on steels suitable for fusion welding are made. It is stated that while higher carbon content steels are successfully welded, present commercial practice limits carbon to 0.30% in open-hearth and 0.15% in Bessemer. Transverse welds in seamless steel pipe are made up to 0.35%. Proposed tentative specifications are offered for normalized and tempered alloy steel for forgings. On forgings not over 14″ diameter or thickness, 7″ maximum wall, properties on Class A are: 80,000 tensile, yield point 0.67 × tensile, elongation in 2″, 28%, reduction 56%. For Class B, 90,000; 0.62 × tensile, 22%, 42%. Compositions stated to give these properties (composition not required) are: Class A, 0.20–0.30% C; 0.80–1.00 Mn; 2.50–3.00 Ni; Cr not over 0.40; V not over 0.05; Class B, 0.42–0.57% C; 0.70–0.95 Mn; not over 0.25 Ni; not over 0.40 Cr; not less than 0.15 V. Those for flange and firebox steels for forge welding require, Grade A, flange 45,000 tensile, yield 0.5 × tensile, and not less than 24,000, elongation in 8″, 1,500,000 ÷ tensile, in 2″, 1,600,000 ÷ tensile. Grade A firebox, same except elongations are 155,000 and 1,650,000 ÷ tensile. Grade B, flange 50,000; 0.5 × tensile, and not less than 27,000, elongation 8″, 1,500,000 ÷ tensile, 2″, 1,600,000 ÷ tensile. Grade B, firebox, same as flange except elongations, which are as in Grade A, firebox. HWG(3)

Permeability of Hipernik Reaches 167,000. T. D. YENSEN. *Electric Journal*, Vol. 28, June 1931, pages 386–388.

Hipernik is a refined iron-nickel alloy, made by removing small amount of impurities, chiefly oxygen, from the ordinary 40–60 alloy. A difference in the amount of aggregate impurities of a few hundredths of 1% accounts for differences in magnetic properties of several hundred percent. Curves compare hipernik with 4% silicon-iron. A maximum μ = 167,000 was obtained from a lot of hipernik, the base of which was manufactured in a commercial steel plant and the punchings from which were annealed in a commercial type furnace. Hipernik is being used in rapidly increasing quantities as cores for instrument transformers. The high permeability and the low loss reduce the ratio errors and phase angle deviations to negligible quantities. WHB(3)

Mechanical Properties of Nickel Steel at Elevated Temperatures. E. PIWOWARSKI & H. NIPPER. *Foundry Trade Journal*, Vol. 43, Nov. 20, 1930, page 360.

Abstract translation of article in *Giesserei*, No. 14, 1930. Gives method and results of investigation. Steels used were melted in basic open-hearth furnace. Composition of the steels:

% C	% Si	% Mn	% P	% S	% Ni	% Cr
0.33	0.36	0.88	0.043	0.030	....	....
0.35	0.31	0.88	0.017	0.025	1.54	0.23
0.35	0.31	0.82	0.017	0.026	300	0.20

Impact hardness of steels decreases with increase of temperature until a minimum value of about 400° C. is reached, then hardness increases up to 600° C. and then it rapidly decreases. Tensile strengths increase from room temperature to 200° C., maximum value at 300° C. Elongation and reduction of area show maxima at between 100° and 200° C. and minima at 300° C. VSP(3)

The Direct Buoyancy Method and the Density of Molten Metals, Especially of Iron Alloys at Temperatures Up to 1600° C. (Ueber die direkte Auftriebsmethode und die Dichte schmelzflüssiger Metalle, insbesondere von Eisenlegierungen bei Temperaturen bis 1600° C.) ERICH WIDAWSKI. Doctor's Thesis. Published by Leo Voss, Leipzig, 1930, 16 pages.

The density of materials, especially of metals in the liquid state, can be very exactly determined by measuring the buoyancy of another material, such as a ceramic body, in it. Certain precautions must be observed and the vessel containing the molten metal must be so arranged that it can be evacuated in order to eliminate errors by gases rising from the melt. The apparatus built for this investigation is described and the theory of the measurement briefly developed. Determinations have been made for tin, copper and copper-tin alloys, iron and steel in liquid state with a carbon content from 0.0 to 4.2% and, in addition, the cubic expansion of refractory materials are given. The volume of Fe-C alloys is found smaller than that computed from the law of mixtures which seems to point to the existence of a compound FeC_3 in the liquid state. Silicon increases the specific volume of liquid Fe-C alloys by 0.0010 cm.^{3}/g. for a Si addition of 1%. Ha(3)

Influence of Rolling and Annealing on the Strength of Thick Sheets. (Einfluss der Walz- und Glühbehandlung auf die Festigkeitseigenschaften von Grobblechen.) K. WALLMANN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 21, 1931, pages 368–369.

Tests were made on 3 German steels and one American steel for structural purposes to find the influence of the degree of change in rolling, rolling end-temperature, annealing temperature and cooling speed on tensile strength, yield point, elongation, reduction of area, notch toughness, and aging. The conclusions are, briefly: great change in rolling and low end-temperature always increase elongation and yield point. Soft steel should not be rolled below 900° C. because it decreases the notch toughness. High rolling temperature will not fully replace subsequent normalizing, although it may reduce the necessity for annealing. Elongation and reduction of area are increased only slightly by annealing. Annealing offers, however, a great advantage if tensile strength or hardness is to be reduced in alloyed or carbon-rich steels to obtain better workability, or if the harmful effect of a cold working is to be eliminated. The tendency to aging becomes a little more pronounced by annealing even if the steel is cooled rapidly. In any case, delayed cooling results in deterioration of the material. Good qualities can be obtained only by quick cooling in air. Ha(3)

Weather-OMeter
and Metal Break Down

Metals and their various alloys in industrial use often are chosen for their weather resisting factors. Containers—whether storage tanks or tank cars or trucks—must frequently withstand arctic cold and tropic heat and safely preserve such widely divergent products as oils—gasoline—acids—alkali.

When any of these questions confront the metallurgist he turns to the Weather-Ometer. It gives him accurate pre-knowledge of the weather resistance limitations of metals under consideration. And in many instances he can foretell with equal accuracy, by Weather-Ometer Tests just how these same metals will be acted upon by the liquids they hold.

Corrosion in metals and alloys, whether from weathering or industrial use factors, can be measured by the Weather-Ometer. Let us explain application. Send for our new bulletin MA-10.

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Combating Corrosion in the Oil Industry. V. V. KENDALL & F. N. SPELLER (National Tube Co.). *Metal Progress* Vol. 19, Feb. 1931, pages 40–45, 113.

Being part of a paper presented before the Western Metal Congress, San Francisco, Feb. 16, 1931, and published in full in the Transactions as "Recent Developments in Corrosion Prevention of Ferrous Metals," with discussion. Accomplishments in corrosion prevention are recounted, addition of 0.25% copper to steel, de-aeration and water conditioning, film-forming inhibitors, suitable coatings for protection against soil corrosion, paints and lacquers for outside protection, new alloys and protective films for protection in the oil industry where corrosion losses are equivalent to 1¢/gallon on the gasoline production. The efforts of the American Petroleum Institute have been very helpful in emphasizing the problem and getting results. Corrosion conditions in the producing fields are described and discussed. Service tests on special steels are reported. Each application requires individual study. WLC(4)

An Introduction to Corrosion Resisting Alloys. CHARLES A. SCHARSCHU (Allegheny Steel Co.). *Metal Progress*, Vol. 19, May 1931, pages 46–49.

The author discusses chromium iron stainless alloys with diagrams showing the effect of 14% and 18% chromium on the iron-carbon diagram. Cutlery applications and heat treatments of higher carbon varieties, with physical properties obtained are given. WLC(4)

The Time Factor in Anodic Passivation of Metals. WILLIAM JAMES SHUTT & VINCENT JACKSON STIRRUP. *Transactions of the Faraday Society*, Vol. 26, Part 2, Nov. 1930, pages 635–642.

Experiments made with a gold anode in acid chloride solution (2N) and with Swedish iron in 2N H_2SO_4 are described. Measurements of the time of passivation and of the time of recovery from passivation were made. The rate of recovery was found to be independent of the strength of the passivating current, while the time of passivation was found to be dependent on both current density and temperature. The results are felt by the authors to be most readily explained on the basis of the oxygen theory elaborated by Muthmann and Freunburger and are very completely discussed in the light of this theory. OWE(4)

Rust Protection of Wrapped Parts. BERNARD JEFFS. *Houghton's Black & White*, Vol. 3, Dec. 1930, pages 18–21.

The importance of maintaining a bright surface on many metal products for sales purposes (tools, precision instruments, etc.) is pointed out and the different treatments in use for anti-friction bearings, razor blades, etc., are described. The selection of the rust preventive has to take into account whether or not an oily, greasy film is objectionable. Ha(4)

Rust Prevention during Shut-Downs. BERNARD JEFFS. *Houghton's Black & White*, Vol. 3, Mar. 1931, pages 16–17; Apr. 1931, pages 17–21; June 1931, pages 14–15.

Attention is called to the fact that lubricating oils are not rust preventives. In the case of scientific instruments, delicate parts, etc., a rust preventive which imparts a hard, dry, tenacious, non-porous film should be used; for tools, a non-drying grade should be employed. Ha(4)

Corrosion Test for Research and Inspection of Alloys. WILLIAM R. HUEY (E. I. duPont de Nemours & Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1126–1143.

Paper presented before the 12th Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The author stresses the need for an accurate corrosion test. The development of composition, and the influence of heat treatment on the corrosion resistance are discussed. A test designed to accurately differentiate between minor changes is described and data obtained by its use are given. WLC(4)

The Initial Corrosion Rate of Steels. H. O. FORREST, B. E. ROETHELI & R. H. BROWN. *Industrial & Engineering Chemistry*, Vol. 22, Nov. 1930, pages 1197–1199.

Concluded from this study, are the following: Oxide-free surfaces of Cr-Ni steels have finite and high initial rates of corrosion which are nearly equal to that of ordinary steel. Cr and Cr-Ni steels resist corrosion in water because of the formation of resistant oxide or hydroxide films on the surface of the metal. Differences in corrosion resistance of steels and steel alloys are due to differences in the physical and mechanical properties of the films formed. 7 references. MEH(4)

Consider Your Wear Problem as a Machining Problem. H. W. GILLETT. *Ceramic Age*, Vol. 16, Dec. 1930, pages 317–320.

The author considers the problem of wear as a type of machining or grinding or, in general, as the removal of metal, and tries, from this point of view, to find the proper materials to resist a particular wear. Hardness and toughness are the properties which every wear-resisting material must possess in a combination to suit a particular case. The various materials at present on the market are discussed and their properties described. Ha(4)

The Chemical Resistivity of Pure Aluminum against Fatty Acids at 80° to 100° C. Normal Operating Temperature. (Ueber die chemische Beständigkeit von Reinaluminium gegen Fettsäuren bei 80–100° C. betriebstechnischer Arbeitstemperatur.) WILLI CLAUS. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 44–47.

Chemical analysis, metallographic and technological tests proved that pure aluminum is practically entirely proof against attack by fatty acids both solid and liquid. A pure aluminum sheet would lose 1 mm. thickness only after more than 10,000 days. Ha(4)

Gmelin's Handbuch der anorganischen Chemie. Eisen. Part A (3). 8th edition. Verlag Chemie, Berlin, 1930. Paper, 7 × 10 inches, 273 pages. Price 40 RM.

This new installment of the volume on iron of Gmelin's Handbook of Inorganic Chemistry deals in 3 main chapters with the passivity of pure and technical iron, the chemical behavior and corrosion and the production of technical iron.

In particular, the first 2 chapters will be of interest for the modern metallurgist who has corrosion problems in his daily work. The first chapter on the passivity of pure and technical iron, written by one of the outstanding German experts in this field, considers the problem from a strictly scientific standpoint which makes it understood that the literature on the subject has been considered in a most comprehensive manner.

It was not possible to deal in this handbook with the corrosion problem from its manifold practical aspects on a large scale. Certainly the 3 authors of the chapter on "Chemical Behavior and Corrosion" have been wise not to do so, but to concentrate their efforts, in searching the literature, on the presentation of a picture which puts in the foreground the course of the reactions in corrosion attack. The difficulties in writing this chapter really seem to be insurmountable. Our gratitude goes to the authors who have done so well in managing them.

The last chapter on the production of technical iron contains one outstanding achievement, inasmuch as it deals in detail with the direct processes of steel making. There will be found the most complete review ever published on all of the many direct steel processes which have been suggested and tried in recent years. Not less than 87 pages are devoted to this subject.—G. Neuendorf (4)-B-

·ILLIUM·

Oxygen as a Factor in Submerged Corrosion. E. C. GROESBECK & L. J. WALDRON (Bureau of Standards). *Preprint* No. 45 for June 1931 Meeting, *American Society for Testing Materials*, 13 pages, 19 references.

Apparatus, wholly of glass and rubber, was used in which tap and distilled water of controlled oxygen content and controlled pH was circulated over the specimens. The pH was controlled by introducing CO_2 for the lower pH and by addition of a trace of NaOH for pH 8. Dissolved oxygen was varied from 1 to 25 cc./liter. Open hearth iron, 0.03% Cu; low carbon steel, 0.08% Cu; copper-bearing low carbon steel, 0.22% Cu; and open hearth iron with 0.43% Cu and 0.07% Mo were studied. The corrosion increased with increasing dissolved oxygen in tap water of pH 7.8 to 8.0. The Cu-Mo iron was not tested in this series. With oxygen above 5 cc./liter the copper-bearing steel showed an advantage, but, as in the case in practice with ordinary city, brackish and mine waters of lower than 5 cc./liter, had no appreciable advantage at lower oxygen concentration, though the corrosion was the less the higher the copper. With higher oxygen, the copper-bearing material was superior by a significant amount. In distilled water with varying pH and varying oxygen, the corrosion rate increased with increase in oxygen in water of pH 5 to 6. In that of pH 4.5, 7 and 8 it increased to a maximum with increase in oxygen and then decreased, apparently due to a passifying action. The materials with 0.22 and 0.43% Cu showed lower corrosion rates than those with lower copper. HWG(4)

Proper Care of Brine Aids Prevention to Corrosion. R. C. DOREMUS. *Heating, Piping and Air Conditioning*, Vol. 3, May 1931, pages 372–377.

Commercial zinc dust has been used to some extent as a corrosion retarder in sodium and calcium chloride brines. The pH value is maintained at 7.5 to 8.0 in such cases. If no zinc is present and the problem is simply to protect the iron and steel the pH should be kept around 9.0 to 9.5. The heavy brines have less corrosive effect on metals than the lighter ones. In sodium chloride brines the use of disodium phosphate (100 lbs./1000 ft.^{3}) reduces the corrosion from approximately 100 to 5%. The charge of phosphate must, however, be renewed once a month. This type of retarder is only practical in sodium chloride brines. Sodium chromate forms a retarder for either sodium or calcium chloride brines. Normal chromate is not easily obtained, therefore sodium dichromate is substituted. This is an acid forming chemical and therefore must be neutralized with alkali to form a neutral chromate and maintain a neutral brine condition. It is customary to use 100 lbs. of sodium dichromate and 35 lbs. of caustic soda/1000 ft.^{3} of brine. WAT(4)

Oxidation of Superheater Tubes by Pure and Impure Steam. (Oxydation der Ueberhitzerrohre durch reinen und unreinen Dampf.) R. STUMPER. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Feb. 1931, pages 41–43.

Tests on scaled superheater tubes are presented. Gives physical chemical ideas on the oxidation of iron by steam and the recent investigations made. Urges further research. MB(4)

Investigation at the Platinum-Hydrogen Electrode. (Untersuchung an der Platin-Wasserstoffelektrode.) M. THALINGER & M. VOLMER (Technische Hochschule, Berlin). *Zeitschrift für physikalische Chemie*, Sec. A, Vol. 150, Oct. 1930, pages 401–417.

The anodic behavior of a hydrogen electrode with bright platinum corresponds to that of metal electrodes as Fe, Cr, Ni, etc., which are subject to passification. The only difference is that the passification phenomenon concerns the hydrogen ions instead of the metal ions. The passivity proved to be a poisoning of the platinum surface by oxygen. The surface film cannot be identified optically. EF(4)

On the Corrosion Phenomena. Seventeenth Communication. Straumanis' Attempt to Interpret the Difference Effect. (Ueber Korrosionserscheinungen. 17. Mitteilung. M. Straumanis' Versuch einer Erklärung des Differenzeffekts.) A. THIEL (University of Marburg). *Zeitschrift für physikalische Chemie*, Sec. A, Vol. 151, Nov. 1930, pages 103–104.

Controversial criticism on Straumanis' interpretation of the phenomenon of the difference effect. EF(4)

Report of Committee A-5 on Corrosion of Iron and Steel. *American Society for Testing Materials, Advance paper* No. 13, June 23–27, 1930, 24 pages.

The Corrosion of the Tin-Plate Container by Food Products. *Department of Scientific Research, Food Investigation, Special Report* No. 40, 94 pages, price, 1s. 6d., net.

Corrosion is one of the main sources of deterioration and loss, for all classes of foodstuffs, whether fish, meat, vegetables or fruit, tend to attack the iron and tin of which the can is made. While the attack may be so severe as to cause actual perforation of the can by small pin holes, the heaviest losses are due to "hydrogen-swells" or "springers," as cans are called in which sufficient hydrogen has been evolved through corrosion to cause the ends to bulge outwards. A third effect of corrosion, and a very insidious one, for it cannot be detected until the can is opened, is discoloration, which may be serious in the case of certain meats, marine products and colored fruit. RR(4)

Cadmium and Zinc as Protection Agent. (Cadmium und Zink als Rostschutzmittel.) *Oberflächentechnik*, Vol. 8, Feb. 3, 1931, page 22.

A critical review of Dr. Patterson's paper on comparative resistance to corrosion of cadmium and zinc coatings exposed under equal conditions to various corrosion agents, which was published in *Chemical Age*, Vol. 23, No. 579, Metallurgical Section. The corrosion tests showed that cadmium as well as zinc, if the coatings are perfect, is suitable for inside-of-building purposes; they behave practically equally. Zinc is superior to cadmium under atmosphere corrosion (outside) and inside of buildings containing corrosive atmosphere. The steel involved contained 0.18% C and was electroplated in zinc sulphate and cadmium cyanide bath. ER(4)

Corrosion of Malleable Iron. F. W. WOLF & L. A. MEISSE (Ohio Brass Co.) in Symposium on Malleable Iron Castings. *Preprint* No. 30 for June 1931 Meeting, *American Society for Testing Materials*, pages 62–75.

Tensile specimens of basic open-hearth steel, ingot iron, wrought iron, all bare, malleable iron, bare and galvanized, and malleable iron with 1% Cu were exposed over 2 years in smoke jacks in a locomotive roundhouse. Comparing the round tensile bars after 25 months' corrosion, the strength in lbs./in.^{2}, figured on original area before corrosion, was ingot iron 27,000, wrought iron 29,000, galvanized malleable 35,000, bare malleable 38,000, bare malleable with 1% Cu 44,000, 0.26% O.H. steel 46,000. The steel started out with 66,500, the others with 45,000 to 49,000. The malleable with 1% Cu showed the lowest loss of strength or of weight. This was checked with another 19 month test on malleable without Cu, with 1/4, 1 and 2%. The attack decreases with increase in Cu up to 1%. Further increase to 2% brings no further advantage. In acid mine water, the higher the copper the worse the attack. HWG(4)

Pipe-Line Currents and Soil Resistivity as Indicators of Local Corrosive Soil Areas. E. R. SHEPARD. *Bureau of Standards Journal of Research*, Vol. 6, Apr. 1931, pages 683–708.

The present tendency in the protection of pipe lines against soil corrosion is away from a uniform coating for the entire length of the line and toward the application of coatings selected with respect to the corrosive character of the soils involved. This calls for a knowledge of varying soil conditions and a means of locating local corrosive soil areas. Such areas, commonly termed "hot spots," are prevalent in many types of soils and it is in these regions that pipe lines suffer the greatest deterioration. The location of such corrosive areas is a matter of considerable importance, both with respect to the selection of coatings for new pipe lines and the reconditioning of old ones. An extensive investigation on a dozen pipe lines ranging from the gulf coast to southern Kansas revealed an apparent correlation between pipe-line currents, soil resistivity and corrosion. Galvanic currents of measurable magnitudes were found to be flowing on all pipe lines examined. As a rule, lines were found to be collecting current in areas of normal and high soil resistivity and losing current in areas of low resistivity. Many cases of abrupt loss or discharge of current occurred in soils of unusually low resistivity. In such areas the pipe lines were found to be badly corroded. Although no direct relation was found to exist between electrical resistivity of soils and their corrosiveness, abrupt changes in resistivity and unusually low resistivity were found to be significant with respect to corrosion. Soils having a resistivity of about 500 ohm-cm. or less were invariably found to be highly corrosive. A better relation between resistivity and corrosiveness exists in alkaline than in acid soils. The technique of surveying pipe lines for galvanic currents is discussed and a piece of apparatus for simply and quickly measuring soil resistivity is described. (4)

Behavior of Sheets of Aluminum, Copper, Zinc and Iron in Contact with Wet Lithopones. (Verhalten von Blech aus Al, Cu, Zn and Fe in Berührung mit feuchter Lithopone.) *Report of the Material Testing Laboratory of the V. A. W., Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, page 52.

Pure aluminum was not corroded while all other materials showed very strong corrosion. The corrosion products were so firmly encrusted that the loss of weight could not be determined. Ha(4)

Corrosion and Metal Protection in Steam Power Plant Equipment. IV. (Korrosion und Metallschutz im Dampfkraftwerk.) R. STUMPER. *Korrosion und Metallschutz*, Vol. 7, Feb. 1931, pages 25–28.

A boiler tube failure from a gas fired furnace using a hard H_2O was investigated metallographically. A deposit of $CaSO_4$ was found to exist throughout the entire length of the tube. Sections of the tube were cut from the tube at the point of failure and at a point some distance from the blowout. Microscopic examinations of the metal surface of both sections revealed decarburization of the outer side of the section which failed, and indicated that the temperature of the inside of the tube had been between the Ac_1 and Ac_3 points, while temperature conditions in the other portions of the tube had apparently been such as to cause no changes in the microstructure. The conclusion was reached that localized overheating due to an impinging flame had caused the failure. (4)

New Method of Determination of Corrosion of Metal Sheets by Motor Fuels. (Neue Methode zur Feststellung der Korrosion von Metallblechen durch Motorenkraftstoffe.) WAWRZINIOK. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, May 1930, pages 65–69.

Liquids at rest attack metals differently from moving liquids. Tests to determine the corrosion in motor liquid fuels must, therefore, be conducted under proper motion. The test arrangement is described. The duration of the test should be from 15 to 30 days. The strongest action was exerted by distilled water, in which tin and aluminum showed up best. In absolute alcohol, brass and aluminum behaved the best. Ha(4)

Practical Methods in Corrosion Prevention. GUY V. THOMPSON. *Refrigerating Engineering*, Vol. 19, Mar. 1930, pages 87–90.

This paper recounts experiences in putting into application the reports of the Corrosion Committee of the American Society of Refrigerating Engineers. Disodium phosphate and zinc dust were used in ice plants where the cans were handled and sodium dichromate in closed systems and where the basket system of can removal was used. In treating a tank with disodium phosphate, the pH value was first adjusted slightly below the neutral point (HCl was used to reduce and caustic to raise the pH) and 100 lbs. disodium phosphate per 1000 cu. ft. sodium brine added. Although this treatment cleared the brine and gave considerable protection, it was necessary to renew the treatment every thirty days and if the brine for any reason gets above the neutral point, the treatment is of no value and the cans begin losing galvanizing and become heavily coated. Because of these difficulties of maintaining the treatment, it was discontinued. Zinc dust was tried (50 lbs. zinc dust/1000 ft.^{3} brine put in in a slurry) with the result that it cleared the cans, coils and tank from rust and scale as efficiently as the phosphate but did not give the protection desired. Sodium dichromate was then used on two New York A-P plants of 160 tons capacity. 100 lbs. sodium dichromate /1000 ft.^{3} calcium brine were added and the pH brought to 7.5 by the addition of caustic. It was found that the further addition of caustic to bring the pH to 9.5 as recommended resulted in precipitation and that the better figure was pH 7.5. About 95% protection was obtained. The use of sodium dichromate for open systems is subject to the danger of chrome itch but it was found that if proper cleanliness was observed, no trouble resulted, only one case of slight infection in twenty-four plants treated was obtained. Leakage of ammonia into the brine makes a very corrosive mixture for galvanizing and the author recommends throwing away the brine if very much acid is required to neutralize the ammonia. After treating 75 plants of various sizes and types since 1926, the author recommends 125 lbs. sodium dichromate/1000 ft.^{3} of calcium brine and 200 lbs./1000 ft.^{3} of sodium brine. A pH of 7 or slightly above is recommended. A high pH value attacks the galvanizing. A warm brine is corrosive and the treatment is added before any salt or calcium as otherwise the galvanizing would be attacked in spots. Corrosion prevention in ice plants is a question of local conditions and if trouble develops it is necessary to apply remedies immediately. In the discussion it was brought out that while sodium silicate will clear the brine it does not stop corrosion. VVK(4)

Preventing Scale Deposition and Corrosion in Boilers. *Industrial Chemist*, Vol. 6, Dec. 1930, page 494.

Notes on the methods and results of the N.O.C. process, by means of which scale can be removed in the form of flakes, or prevented from depositing, by means of a small current passed through the outer vessel. The cost of operation is about equal to that of burning one 100-watt lamp for each boiler, and the process is very efficient. MPB(4)

Stainless Steels for Automotive Parts. M. J. R. MORRIS. *S. A. E. Journal*, Vol. 28, Feb. 1931, pages 204–209.

Author shows that stainless steel should be divided into 3 classes, according to whether they are to resist corrosion under atmospheric, wet or heat conditions. Every trace of scale, iron oxide and contact with iron that might oxidize must be eliminated from the surface to prevent staining, which will extend far beyond the contamination. Basic compositions of steels in the 3 classes are tabulated, and the physical properties of a few of them are given. A bibliography of articles and books on stainless steels is appended. MFB(4)

Metallography & Macrography (5a)

Classifying Hardened Tool Steel Fractures. Correspondence from E. Oehman, Stockholm, Sweden. *Metal Progress*, Vol. 19, June 1931, pages 88–89.

Method of classifying and grading tool steel devised by Dr. Ragnar Arpi is briefly described. WLC(5a)

Etching Nickel and Its Alloys. W. A. Mudge. *Metal Progress*, Vol. 18, Dec. 1930, pages 72–73.

The author accompanies a description of flat and electrolytic etching reagents with 5 micrographs of nickel alloys showing the action of the reagents described. WLC(5a)

Constitutional Diagram Iron–Oxygen System. C. H. Mathewson. *Metal Progress*, Vol. 19, Apr. 1931, page 83.

A full page chart of this constitutional diagram is taken from the manuscript of a paper received Feb. 13, 1931, for the Transactions, "Evolution of the Iron-Oxygen Constitutional Diagram" by Mathewson, Spire and Milligan. WLC(5a)

Application of Cementation Methods of the Systems: Sb–Cd, Zn–Cd, Pb–Cd, Sn–Cd and Bi–Cd. Wl. Loskiewicz. *Przeglad Techniczny*, Vol. 69, June 25–July 2, 1930, page 508–513.

A cementation method as described elsewhere (Przeglad Gorniczo-Hurniczy, 1929, page 583) was employed in investigating the cementing characteristics of the systems Sb–Cd, Zn–Cd, Pb–Cd, Sn–Cd and Bi–Cd, on which cementation below the eutectic temperature forms permanent openings at the junction. By cementation at temperature above the eutectic temperature, the eutectic is formed followed by fusion at the junction, and therefore the absence of permanent openings. Tests carried out below the respective eutectic temperatures showed no evidence of cementation, while those cemented 3% above the eutectic temperature showed fusion and qualities of the eutectic. Methods employed are discussed. In the Sb–Cd system, CdSb is formed at the junction, while in the other systems investigated, eutectics were formed in every case. In the system Bi–Cd, there exists a fusion in a stable form and in the other systems, tests corroborate the existence of such fusion. GLC(5a)

A Note on the Constitution of the Cadmium-Zinc Alloys. D. Stockdale. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 75–82.

Includes discussion. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 844. (5a)

Microscopic and Thermal Investigations of Al-Sb-Mg Alloys. (Mikroskopische und thermische Untersuchung von Al-Sb-Mg-Legierungen.) E. Loofs-Rassow. *Aluminium, Hauszeitschrift der V. A. W. und Erftwerke A. G.*, Vol. 3, Jan.-Mar. 1931, pages 20–32.

Alloys of aluminum and manganese with additions of antimony have proven particularly resistant to sea water; their properties, however, have not yet become entirely known. The present investigation discusses first the binary systems Al–Mg, Mg–Sb and Al–Sb, and then the ternary system Al–Sb–Mg from which it can be concluded that the addition of Sb produces the formation of a new structural element Mg_3Sb_2, antimonide of magnesium, which is only slightly soluble in Al; with increasing temperature, the solubility increases. Tables and micrographs illustrate the results. Ha(5a)

On the Art of Metallography. Francis F. Lucas (Bell Telephone Laboratories, Inc.). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 421, 1931, 36 pages.

The Howe Memorial Lecture before the American Institute of Mining & Metallurgical Engineers, Feb. 1931. The first part of the lecture consists in a description of microscopic methods. It is pointed out that competent technicians as well as good equipment are necessary to obtain the full possibilities of the microscope. The objective is the most important part of the microscope. Methods for testing objectives are given. The structures of heat treated steels are discussed in the second part of the lecture, and the marked advances in the rendering of detail resulting from the authors work are described. Real images of detail that measure but a few hundred atom diameters have been developed, and clearly defined details of structure that are by actual measurement only a fraction of the wave length of the light used have been clearly defined. Numerous small cracks have been observed in hardened steels, and it is suggested that these cracks may account for the erratic fatigue results obtained with such steels. The cracks observed were as small as 2.86×10^{-3} in., which is only 16% of the dominant wave-length of light used. The measured length of the cracks ranged upward from 11.44×10^{-6} in. The minimum widths of the cracks were therefore of the order of 250 atom diameters. As a conservative estimate, the enlargement by etching was by a factor of 10, which means that the actual width of the smallest visible crack is probably of the order of 25 atom diameters. Contains 8 references. JLG(5a)

The So-Called Heterogeneity of Martensite. E. Maurer & G. Riedrich. *Iron Age*, Vol. 126, Dec. 11, 1930, page 1775.

Abstract translation of article in *Stahl und Eisen*, Oct. 9, 1930. Discusses the cause of irregular distribution of precipitated cementite in steels tempered at 1100° to 1200° F. See *Metals & Alloys*, Feb. 1931, page 34. VSP(5a)

The Kinetics of Recrystallization. (Zur Kinetik der Rekristallisation.) R. Karnop & G. Sachs. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 86–92; *Zeitschrift für Physik*, Vol. 60, 1930, pages 464–480.

Electrolytic Cu was cast, turned to a specimen with a conical section, annealed at 480° C. for 1/2 hour, stretched in a testing machine, and the reduction at various points measured, so as to give a specimen with a known graded degree to reduction (3 to 18%). The specimens were then annealed for various times at 284°, 341° and 370° C., and examined for recrystallization. At 370° C. it occurred in 2 minutes at 14% reduction, and in 800 minutes, at 3%. At 341° C. in 5 minutes at 14% reduction, and in 1000 minutes, at 5%. At 284° it took about 30 minutes at 18%, and over 1000 minutes at 11%. The curves for percentage reduction (cartesian scale) against annealing time in minutes (logarithmic scale) are almost a straight line for 284°, but slightly concave toward the percent reduction axis for the higher temperatures. Similar plotting of the rate of growth of grains during recrystallization gives again nearly a straight line for the lower temperature, and slightly curved ones for the higher temperatures. The growth of crystals in the recrystallization of Al was similarly studied. Various mathematical expressions are given for the kinetics involved, for which the original should be consulted. HWG(5a)

Polishing Procedure for Minerals. (Aus der Praxis des Erzanschliffes.) Werner Gründer. *Metall und Erz*, Vol. 28, March 1931, pages 143–147.

Contains 2 references. A detailed procedure is described for polishing specimens of minerals and coal for microscopic examination. A flat specimen is preferable to one polished in relief. Rough grinding is done on No. 80 or No. 200 carborundum at 1600 r. p. m. for 5 to 10 minutes. It is better not to grind the edges of minerals, as most of them are brittle and are liable to crack. The second step is polishing on emery paper mounted on a disk revolving at 500 to 800 r. p. m. This operation should take about 1 hour. Good results are obtained by wetting the specimen with a mixture of 4 drops water, 7 cc. lubricating oil and 5 g. emery. In this case the disk speed should be 300 r. p. m. The specimen is then washed with xylol or toluol. Final polishing is done on billiard table cloth at 500 r. p. m. using a mixture of 1 part MgO and 3 parts Al_2O_3. The specimen should be turned constantly during polishing. Eight photomicrographs are given. CEM(5a)

The AMINCO Automatic Metallographic Polishing Machine

Patent Applied for

THIS new machine is based upon a similar one, developed by the U. S. Bureau of Standards' engineers, to effect a standardization of methods employed in polishing specimens for microscopic examination. To their design we have added several improvements of our own and can now supply the machine as pictured above, ready for use in the laboratory. It produces a remarkably high polish, free from pits and "comet-tails", such as occur on specimens that are hand polished and showing perfect formation of inclusions, with practically no rounding-off of edges of the cracks. It accomplishes this automatically, polishing three specimens at the same time, without requiring the constant attention of a high-salaried technician. This new machine will very quickly save many times its cost in any metallurgical laboratory. A bulletin describing it in detail will be sent to you promptly, upon request.

774 Girard St., N. W. Washington, D. C.

The Macroexamination of Steel. M. G. Yatsevitch. *Army Ordnance*, Vol. 11, Jan.-Feb. 1931, pages 297–305.

This 7200-word article almost amounts to a text book—brief but up-to-date. Thorough discussions on preparation methods, consideration of objects of tests, etc. Examples given. Three excellent tables on quantity of reagents, etching times, etc. Discussion of interpretation of picture revealed on surface of metal. MFB(5a)

Thermal Analysis and Dilatometry. H. Scott (Westinghouse Elec. & Mfg. Co.). *First Communications of the New International Association for the Testing of Materials.* Group A, Zurich, 1930, pages 339–344. 14 references.

General discussion of the applicability of thermal analyses, dilatometry and magnetic and electrical methods to metallurgical problems. HWG(5a)

Critical Ranges in Pure Iron-Carbon Alloys. The A_3 and A_{cm} Ranges, and the Merging Point of A_3 and A_2. R. H. Harrington (General Electric Co.) & W. P. Wood (University of Michigan). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 632–658.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion, 13 references, 24 micrographs. 32 steels prepared by the methods of E. D. Campbell of 0.000–1.500% carbon. Diagrams show the critical points obtained on heat treated specimens, on cooling specimens, and an average of the 2 curves. Space diagrams showing the possible rearrangements when γ iron changes to α are given. 6 critical curves are shown representative of the carbon range studied. WLC(5a)

The Electrolytic Decomposition of Cementite and Austenite. H. A. Schwartz, G. H. Guiler & H. H. Johnson (National Malleable and Steel Castings Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 718–728.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion and three references. Compositions and nature of the electrolytic residues from cementite and austenite are studied and discussed. WLC(5a)

A Study of the Tungsten-Carbon System. W. P. Sykes (Cleveland Wire Works, General Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 968–992.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion and is illustrated with 27 micrographs and 6 X-ray spectrum, 5 references. The author presents a tentative constitutional diagram of the system tungsten-carbon for the tungsten rich end, up to 11% carbon. WLC(5a)

A Thermodynamic Study of the Equilibria of the System Antimony-Bismuth and Antimony-Lead. Chu-Phay Yap. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 397, 1931, 24 pages.

A thermodynamic study of the Bi-Sb system indicates that the horizontal position of the solidus as determined by thermal methods may result from the reaction $\beta(Sb_2\text{-}Bi_3) \rightleftharpoons \alpha(Sb_2\text{-}Bi_2)$, these expressions indicating solid solutions. The formation of the phase Bi_3 in solid solution in Sb_2 may result from a peritectic reaction. The heats of fusion of Bi and Sb are calculated as being 14.2 and 20 cal./g., respectively. Analysis based on the variation of solid solubility of Sb in Pb and the slope of the liquidus and solidus indicates that the Sb in solution in the lead suffers an allotropic transformation at about 150° C. It appears that in the liquid lead-rich solution Sb is monatomic, and that in the solid solution above 150° C. it is diatomic, while below this temperature it is monatomic. Contains 14 references. JLG(5a)

Progress of Microscopy. H. Wrighton (Woolwich Arsenal, England). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 366–368.

Very brief reference to recent British advances. HWG(5a)

Fundamentals for the Use of Alloyed Steels. R. Whitfield. *Iron & Steel Industry & British Foundryman*, Vol. 3, Aug. 1930, pages 347–350.

The influences of alloy additions upon the transformation point and the properties of pearlitic, troostitic, martensitic and austenitic steels are discussed. CHL(5a)

Thermal Analysis of Iron-Manganese Alloys. F. M. Walters, Jr. & Cyril Wells. *Mining & Metallurgical Investigations U. S. Bureau of Mines & Carnegie Institute of Technology, Mining & Metallurgical Advisory Boards*, 4th Open Meeting, Oct. 17, 1930, 6 pages.

Thermal analyses were made in a gradient furnace on Fe-Mn alloys containining 1.7, 4.4, 7.2, 10.2, 13.1 and 16% Mn with an average of 0.02% C. A sudden change in thermal disturbance was observed in alloys containing 13 and 16% Mn. (5a)

Influence of Nickel on the Chromium-Iron-Carbon Constitutional Diagram. V. N. Krivobok & M. A. Grossman. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 808–836.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion and 3 references. The paper is amplified by 29 micrographs, and numerous diagrams and figures. The extent to which nickel widens the austenite field is illustrated in analogues of iron-carbon diagrams, the "iron" being an alloy with 18% chromium and the added nickel. Nickel widens the range of temperature in which austenite is stable, the range of carbon content in which it is stable is also widened and the carbon range where ferrite and austenite together are stable is narrowed. Magnetic and hardness data are given with a discussion of the precipitation of the carbides at 1200° F. WLC(5a)

Austenite Decomposition and the Change in Magnetic Properties. Harley S. Van Vleet & Clair Upthegrove. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 729–759.

Manuscript received July 29, 1930. 12 references to the literature. The authors have investigated the relation between magnetic properties and retained austenite in 5% tungsten magnet steel. The austenite was decomposed by tempering and by quenching in liquid air. The findings show that more austenite was retained in the specimens quenched from higher temperatures indicated by the greater density change upon quenching and by the secondary hardness effect during tempering. Bars show decreasing density with more drastic quenching medium. A tempering range of 977–1121° F. most readily decomposed the austenite. The effect of the two methods of decomposing the austenite on the physical and magnetic properties are:

Property	Tempering	Liquid Air Treatment
Density	decrease	decrease
Hardness	increase	decrease
Maximum induction Bm	decrease	increase
Residual induction Br	increase	increase
Coercive force Hc	increase	decrease
Product Br × Hc	increase	increase
Quotient Br/Hc	decrease	increase
Maximum of permeability B/H	decrease	increase

LEITZ-OGRAPH

Your Metal Samples as a guarantee for unfailing and reliable results

LEITZ MICRO-METALLOGRAPH "MM"
(Inverted Microscope with Camera)

Preparing the metal sample in a faultless manner is the first step toward a perfect micro-analysis

The "Guthrie-Leitz" Automatic Polishing Machines, of ONE-, TWO-, and FOUR-Spindle Type, by means of a magnetic holding and oscillation device, produce these results in an automatic manner, eliminating all elements of human equation. These Automatic Polishing Machines represent a distinct labor saving device, thereby repaying their cost in a short time.

As the next step toward an unfailing micro-analysis, the microscope equipment should be perfect mechanically as well as optically.

The Leitz Micro-Metallograph "MM" possesses all the required qualifications to render a microscopic image of unequalled brilliancy, definition and flatness of field.

STRUCTURE OF METALS & ALLOYS (5)

Structure & X-ray Analysis (5b)

X-ray Investigation on the System Sulphur–Selenium. (Röntgenographische Untersuchung im System Schwefel-Selen.) F. HALLA & F. X. BOSCH (Technische Hochschule Vienna). *Zeitschrift für Physikalische Chemie*, Sect. B, Vol. 10, Oct. 1930, pages 149–156.

The most important data concerning the structural arrangement of the rhombic solid solutions of Se and S were determined by X-ray investigation. EF(5b)

X-Ray Studies of Quenched Steels. Correspondence from A. WESTGREN (Stockholm). *Metal Progress*, Vol. 19, Mar. 1931, pages 87–88.

The writer describes technique and results of X-ray studies of Öhman at University of Stockholm in analyzing the tetragonal phase in quenched carbon steel. WLC(5b)

Suppressions in Alloys of Manganese. Correspondence from A. WESTGREN (Stockholm). *Metal Progress*, Vol. 19, Feb. 1931, pages 86–87.

The writer reports with diagrams certain complex tendencies noted in an X-ray study of systems Fe–Mn and Cu–Mn by Öhman and Persson at the University of Stockholm. WLC(5b)

X-Rays Detect Twin Crystals in Alpha Iron. N. P. Goss (American Steel & Wire Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1238–1245.

Three references are cited. Previously it was found that low carbon steel drastically cold-rolled and heat treated showed a new orientation developed during annealing. This study shows what conditions of cold work and heat treatment are necessary to develop this new orientation. WLC(5b)

X-Ray Investigation of the System Sulphur–Selenium. (Röntgenographische Untersuchung im System Schwefel-Selen.) F. HALLA, E. MEHL & F. X. BOSCH. *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 12, May 1931, pages 377–386.

Space lattice and pattern of mixed crystals of Se and Te were determined by X-ray investigation. The unit cell contains 32 atoms and yielded the following parameters: $a' = 8.48$ A. U., $b' = 13.34$ A. U., $c' = 8.33$ A. U. and $\beta = 67° 30'$. The density = 2.833. EF(5b)

X-Ray Testing of Large Boilers in Service. (Röntgendurchstrahlung im Grosskesselbetrieb.) A. HERR. *Zeitschrift Verein deutscher Ingenieure*, Vol. 74, Oct. 11, 1930, pages 1432–1433.

An arrangement is described whereby large tanks, drums, etc., are tested by X-rays on site. The X-ray tube is installed in the interior and exposures on films taken on the outside. One exposure lasted 30 min. at 145 KV. The films were 15 × 40 cm. Ha(5b)

Space Lattice of Cementite. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 18, Nov. 1930, pages 87–88.

Dr. Honda reports determinations of Fe_3C space lattice dimensions by Shimura at Tokio as, a = 4.511, b = 5.047, c = 6.738 A. U. Diagram is given. Fe_3C has a simple orthorhombic lattice with 4 molecules to the cell. WLC(5b)

X-Ray Inspection of Welded Pipes and Pressure Equipment. H. R. ISENBURGER. *Heating, Piping and Air Conditioning*, Vol. 3, April 1931, pages 304–305.

With the growing use of welded materials in high-pressure, high-temperature services the need for a means to prove the soundness of the structure appeared. X-rays are being used to meet this need. The article describes the set-up and shows photographs of the results obtained. WAT(5b)

X-Ray Examination of Steel Gas Flasks. (Röntgenprüfung von Stahlgasflaschen.) C. KANTNER. *Autogene Metallbearbeitung*, Vol. 23, Oct. 15, 1930, pages 317–324.

The continuous examinations of steel flasks for gases during their manufacture and the equipment necessary are discussed. Tests are described and economy investigated. Numerous photographs of X-ray pictures illustrate the defects found in finished flasks. Continuous supervision of the filled flasks by means of X-ray is found to contribute to the safety of plants and storage. The cost of the examination for one flask, including materials, amortization of equipment, electrical energy and overhead, were, in one case, found to be Mk. 2.38 ($0.59). Ha(5b)

X-Ray Testing of Compressed Gas Flasks. (Röntgenprüfung von Druckgasflaschen.) C. KANTNER & A. HERR. *Autogene Metallbearbeitung*, Vol. 24, June 1, 1931, pages 167–171.

Continuing a previous investigation, additional material has been collected to show defects in manufacture and violations of rules in manufacturing. A portable installation for shop tests is described. The whole X-ray outfit costs RM 6500; 15 flasks could be tested in one hr., including the taking of 15 exposures. The expenses for the testing of one flask amounted to RM 1.43, inclusive of films and chemicals. Ha(5b)

X-Ray Investigation of Coagulation Phenomena of Colloidal Gold. (Röntgenographische Untersuchung des Koagulationsvorganges bei kolloidalen Gold.) P. SCHERRER & H. STRAUB. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 154, May 1931, pages 309–321.

The coagulation of highly dispersed gold solutions is investigated by means of X-rays and the conditions were established leading to collective crystallizations of the primary particles. The effect of inhibitors was furthermore studied. EF(5b)

X-Rays in the Steel Industry. H. H. LESTER (Watertown Arsenal). *Journal of the Franklin Institute*, Vol. 211, May 1930, pages 567–579.

General discussion. Increasing demand for better steels will be met largely by improvements resulting from basic information obtained by means of X-ray diffraction studies. X-ray inspection eliminates unsound metal and aids in developing manufacturing technique that will produce sound metal. MS(5b)

Radiography by the Use of Gamma Rays. R. F. MEHL, G. E. DOAN & C. S. BARRETT. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1192–1237.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion, and 12 references. The authors detail the technique developed for the use of γ-rays for the radiography of much thicker steel specimens than it is possible to examine with ordinary X-rays. The technique and results presented are discussed. WLC(5b)

X-Ray Study of Grain Size in Steels of Different Hardness Values. W. A. WOOD. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Dec. 1930, pages 1073–1081.

Measures the broadening effect of 10 samples of stainless steel having the same chemical composition but of different hardness. Discusses the relation between measured grain size and hardness. Hardness varies inversely as the superficial area of the grains. RHP(5b)

Crystal Structure in the System Copper–Bismuth. WILLIAM F. EHRET & RAY D. FINE. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Oct. 1930, pages 551–559.

A series of alloys from pure Cu to pure Bi was examined as to structure. All the alloys examined were heterogeneous, showing clearly the superimposed patterns of Cu and Bi. The lattices of Cu and Bi remained unchanged in their alloys. This indicates very low mutual solubility. The lattice constant of the face-centered unit cube of Cu is $A_0 = 3.607 \pm 0.004$ A. U., and Bi 4.749 ± 0.005 A. U. RHP(5b)

X-Ray develops correct welding technic

HERE we show radiographs of two welds made by the same individual but with two different welding methods. The fact that one shows as a perfect weld, proves that with a given method one may become skilled when the x-ray is used as a means of developing a correct technic.

Leading manufacturers are now using the x-ray extensively to check on ***methods*** before production is begun. Thus manufactured products worth thousands of dollars are saved from the scrap heap. Why not investigate? Let us send you a copy of "Industrial Application of the X-Ray." For convenience, use the coupon. We will gladly collaborate with you in tests to show what use your firm can make of the x-ray.

The procedure usually followed is to increase the blank holder load using blanks of the same diameter until failure occurs.

While it may be possible that two sheets can be drawn from the same maximum diameter, one of them may stand a higher blank holder load than the other. This one would have to be called the better sheet for drawing purposes.

If the two sheets mentioned would, however, show failure at exactly the same blank holder loads there is still a chance of differences in deep drawing forces. It seems logical to call that one the better sheet which requires smaller drawing forces to give the same cup under identical conditions.

Nickel Manganese Steel Welding Rod

The following claims are made for the AMSCO Nickel Manganese Steel Welding rod:

Perfect welds can be made by relatively unskilled operators. When the rod is melted in the atmosphere and applied to ferrous metal articles, it exhibits the essential characteristics of standard heat treated manganese steel, namely toughness, ductility, resistance to abrasion and hardening under cold working.

The high nickel content (approximately 5%) overcomes any tendency of the metallic manganese content of the rod to oxidize and prevents embrittlement under slow cooling, which the rather high carbon content might cause in the absence of the high nickel content.

The patent claims granted on this welding rod are very broad covering ranges of all principal elements as follows:

Iron	90.00% to 25.00%
Manganese	5.00% to 25.00%
Carbon	0.50% to 2.00%
Nickel	0.25% to 50.00%

The preferred formula designated as "A" in the patent is as follows:

Iron	about 80.00%
Manganese	14.00%
Carbon	1.30%
Nickel	5.00%
Silicon	0.35%

This may be compared with an actual analysis taken of a recent rolling of a carload of AMSCO Manganese Steel welding rod now in stock:

Iron	about 80.00%
Manganese	13.72%
Carbon	1.22%
Nickel	5.00%
Silicon	about 0.50%

Micro-Indicator Stand with Vee-Block Table

A modification of their Micro-Indicator Stand U-3 is being offered by the Société Genevoise d'Instruments de Physique through their agents, the R. Y. Ferner Company, Investment Building, Washington, D. C., in which a vee block is furnished as the table, adapting it to the support of small cylindrical pieces, from $^1/_8$" to 2" in diameter, as shown at left of illustration, for the measurement of their diameter or roundness.

Larger pieces, up to a maximum of 6" in diameter, can be checked on a large flat table $4^1/_8$" diameter as shown at right. This table is case hardened and lapped and is provided with cross grooves to eliminate dust on the surface and provide for a good contact with the standard flat gage blocks when they are wrung onto it to establish the zero setting of the instrument.

An adjustable square is also furnished, for attachment to the column of the stand, which serves as a stop piece against which cylindrical test pieces can be rolled to the correct position for reading on their diameter. The micro-indicator used in these measurements has adjustable tolerance marks which can be set at any desired point up to .003" either side of the zero. The indicator is also provided with a lifting clip by which the contact plunger can be raised for the insertion of the work piece beneath the spherical or flat contact anvil without the necessity of rolling or sliding the piece under the anvil each time with resulting wear of the contact surface. These facilities make rapid inspection of parts an easy matter.

The micro-indicator can be supplied graduated to $^1/_{2000}$, $^1/_{5000}$, $^1/_{10,000}$ or $^1/_{20,000}$ inch per division according to the grade of accuracy demanded. The instruments are guaranteed to read accurately to 1% of the total range of the dial which varies from .02 to .006 inch according to the manner of graduation.

New Normalizing Oven

Normalizing sylphon devices has presented a serious and intricate problem to manufacturers for many years. Many types of ovens, including crude homemade equipment, have been used without success.

While uniformity seemed apparent, the sylphon switches in operation gave very unsatisfactory service. Stresses and strains had not been properly removed in the normalizing process.

Recently, a midwestern electric refrigerator manufacturer selected the type S oven of the Despatch Oven Co., Minneapolis, Minn., which has an electric heating system externally mounted, and a recirculating ventilating system.

The oven has sufficient capacity for 1800 sylphon units at one time which are loaded on trucks and pushed into the oven. After parts are in the oven at a constant temperature for a sufficient length of time, they are removed. Normalizing is done uniformly and quickly.

The oven is a new development for this type of work. It has the double wall panel construction with highly efficient rockwool insulation between. Oven can be knocked down and moved whenever desired.

A 6 k.w. heating system is mounted in a separate chamber on top of the oven. An electric fan forces air through this heater and down into heat ducts in the oven. By proper graduation of ports in the ducts correct distribution of the heat is secured.

The air is then uniformly circulated around the parts in the oven by means of a recirculating ventilating system. Other ducts, properly located in the oven and also graduated, are interconnected with the electric fan which forces air through the heater. By this system, the temperature in the oven is maintained within ± 4° F. in all parts and normalizing is uniform and thoroughly done.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Magnetic State of Platinum. (**États magnétiques du platine.**) P. COLLET & G. FOËX. *Comptes Rendus*, Vol. 192, Apr. 20, 1931, pages 930–932.

Collet and Foëx describe the results of tests on 4 samples of platinum, which were apparently identical in character when otherwise examined but which showed distinct differences in the magnetic state when tested by magnetic measurements of the highest precision. In particular, reference is made to a change in magnetic state at a temperature about −110° C. This particular sample of platinum in the initial series of experiments gave a value of 12 magnetons, a value which was never reproduced in subsequent experiments. OWE(6)

Electrical Testing of Materials without Destruction of the Material Tested. (**Werkstoffprüfung mit Hilfe des elektrischen Stromes ohne Zerstörung des zu prüfenden Werkstoffes.**) M. FINK. *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 85, July 1930, pages 329–332.

Refers to the testing method of Sperry, The method, developed in the U. S. A., is described at length and illustrated. EF(6)

The Microcharacter. CHRISTOPHOR H. BIERBAUM (Lumen Bearing Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930 pages 1009–1025; *Metal Progress*, Vol. 18, Nov. 1930, pages 42–44.

Paper presented before the Twelfth Annual Convention of the Society Chicago, Sept. 1930. Includes discussion the author describes his "Microcharacter hardness tester" used for testing the hardness of small areas and very thin sections. Method of operation is detailed and curves are shown of results on nitrided and carburized cases. WLC(6)

Stresses in Fillets. E. F. GARNER. *Product Engineering*, Vol. 2, June 1931, pages 259–261.

Concentrated stresses in fillets may cause the birth of "fatigue cracks," especially in brittle materials. Even low-carbon steels subjected to vibratory stresses may fail because of high stresses in small fillets or sharp corners. Curves and tables are given for the calculation of the stresses. This calculation is illustrated by an example. Ha(6)

Endurance of Electroplated Parts Studied. Correspondence from C. H. DESCH, Sheffield, England. *Metal Progress*, Vol. 19, Apr. 1931, pages 92–93.

Notes on the effect of electroplating various metals on the fatigue resistance of the plated parts. WLC(6)

Torsional Testing of Wire. ALEX. GLAZUNOV. *Wire & Wire Products*, Vol. 6, Apr. 1931, pages 130–131, 149–150.

The importance of the torsional test for wires is pointed out as being greater than bending or tensile tests. The following suggestions are submitted: (1) The torsion or twisting test shall be considered as important in the selection of wires for specific purposes. (2) An optional minimum of twists shall be adopted for particular grades of wires. (3) The load under which the number of twists is to be determined shall be expressed in % of the average of the actual tensile strength for each grade of wire under examination. (4) The testing load for torsion shall be conventionally 1, 2 or 3% of the actual tensile strength of the wire. (5) The ruptured end of the tested specimens shall be smooth and the distribution of twists over the entire length of the sample shall be absolutely uniform. A testing machine is described and convenient dimensions for sample and load proposed. Curves and tables show the relation between load and number of twists until rupture occurs. Ha(6)

The Notch Toughness of a Few Aluminum Alloys Especially at Low Temperatures. (**Ueber die Kerbzähigkeit einiger Aluminiumlegierungen insbesondere bei tiefen Temperaturen.**) W. A. GÜLDNER. *Zeitschrift für Metallkunde*, Vol. 22, Dec. 1930, pages 412–416.

Conclusion of previously published article (See *Metals & Alloys*, Vol. 2, Feb. 1931, page 37). The influence of velocity of test, of the width of the test piece, and of the depth of the notch, all at −190° C. was studied. The relations between these conditions is exposed mathematically and graphically, and discussed at length with comparison to Fe alloys. RFM(6)

Testing of Materials, Principles and Recent Research Results. (**Ueber die Prüfung der Werkstoffe, Grundsätzliches und neuere Forschungsergebnisse.**) OTTO GRAF. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 2, 1931, pages 537–542.

A general discussion of short-duration tests for determining the guarantees given for building materials, steel, concrete, wood. All tests should follow, as closely as possible, actual service conditions. 25 references are given. Ha(6)

Stress Distribution in Bolted Structures. (**Ein Beitrag zur Frage der Spannungsstörungen in Bolzenverbindungen.**) G. BIERETT. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 15, 1931, pages 3–39.

Tests of stress distribution about bolt holes and elsewhere in a large eye-bar for a bridge. The highest load applied was about 11,000,000 lbs. Higher stresses than the tensile strength of the material in ordinary tests can be resisted, if plastic deformation is hindered. Failure depends on the "Trennfestigkeit" of the material as well as its tensile strength. The maximum unit load resisted by the eye-bar was equivalent to the tensile strength of the steel after stretching 18%—i. e., the effective strength was 16% higher than that of the original annealed steel in the tensile test. HWG(6)

On the Effect of Cold-Working on the Density and Electric Resistance of Metals. T. UEDA. *Kinzoku no Kenkyu*, Japan, Feb. 1931, pages 53–71; *Science Reports of Tohoku University*, Vol. 19, 1930, pages 473–498.

Specimens of steel, copper and brass, 5 mm. in diameter and 200 mm. in length were annealed thoroughly. They were stretched by testing machine and electrical conductivity was measured in machine oil. Density was calculated from the external force applied. The results were as follows: The density gradually decreases with the increase of stress, and its rate is constant up to the yield point, beyond which it rapidly increases. The discontinuous decrease of density at the yield point decreases as the carbon content increases, and almost vanishes at 0.9% C. This is due to the decrease of plasticity with the carbon content, or the formation of minute cavities caused by internal slipping is not so great as in the case of low carbon steels. In the case of copper and brass, the density decreases almost linearly to the yield point and then rapidly decreases. The cause of these changes may be explained in the same way as in the case of carbon steels. The specific electrical resistance of Armco iron and 0.2% carbon steel increases linearly up to the yield point, at which a discontinuous increase of resistance is observed, and afterward, it increases linearly. As the content of carbon increases, the increase of the specific resistance below the yield point diminishes, and at that point the specific resistance decreases instead of increasing as in the former case. Beyond the yield point, the specific resistance increases but the total increase becomes less as the carbon content increases. The initial increase of specific resistance is due to the decrease of free electron caused by the decrease of density by applied force. The rapid increase above the yield point is principally due to the minute cavities in metals. In low carbon steels, the specific resistance abruptly increases and in high carbon steels, abruptly decreases at the yield point. This phenomenon is explained as follows: At the yield point, the metal undergoes a great amount of internal slipping, this causing minute cavities and resulting in an increase of resistance. On the other hand the yielding reduces the initial strain and causes a decrease of resistance. Thus, during the yielding, two opposite effects on the electric resistance are concurrent. In low carbon steels, the initial slipping is considerable and the specific resistance increases; in high carbon steels, the internal slipping is not caused so freely and hence the resistance decreases. Wear Resistance of Nitrided Nitralloy. V. O. Homerberg & J. P. Walsted. *Metal Progress*, Vol. 18, Dec. 1930, pages 68–71.

Wear is defined and its nature analyzed. An apparatus for wear testing is described. Tests of nitralloy against itself, gray cast iron, white cast iron, Monel and 3 bronzes were made. Results indicate great possibilities for nitrided material in machine and engine parts subject to severe conditions of wear or difficult to lubricate. WCL(6)

Sharpness Tests for Different Razor Blades. Correspondence from K. Honda, Sendai, Japan. *Metal Progress*, Vol. 19, Mar. 1931, pages 88–89.

The writer describes equipment for testing sharpness of razor blades and gives results of such tests on 21 blades made in 6 different countries. WLC(6)

Aging Notch-Toughness and Etching of Force-Effect Figures. (Alterungskerbzähigkeit und Kraftwirkungsfiguren-Aetzung.) H. Jungbluth. *Krupp'sche Monatshefte*, Vol. 12, May 1931, pages 106–112.

More recent investigations have proved the reliability of the theory that a certain relation exists between the figures of action of force and the aging and notch-toughness of a steel. Numerous tests are described in detail and 26 references are cited. Ha(6)

The Notched-Bar Impact Test, a Further Résumé in the Light of Present Knowledge. J. M. Lessells, Chairman A. S. T. M. Sub-Committee on Impact Testing. Appendix IV to *Preprint* No. 4, Report of A. S. T. M. Committee E-1 on Methods of Testing for June 1931 Meeting, *American Society for Testing Materials*, 3 pages, 4 references.

The ability of the impact test to reveal faulty material is now evident. The results of Mailänder and Moser on effect of dimensions of test specimen are briefly discussed. HWG(6)

Fatigue Tests of Low-carbon Steel at Elevated Temperatures. Progress Report. H. F. Moore & N .J. Alleman (Univ. of Illinois). Appendix 1 to Report of Joint Research Committee on Effect of Temperature on the Properties of Metals. In *Preprint* No. 29 for June 1931 Meeting, *American Society for Testing Materials*, 8 pages, 3 references.

Fatigue tests were made on a normalized 0.17% C, 0.42% Mn steel in a rotating spring testing machine at 550°, 800° and 1200° F., at 2500 and 200 r. p. m. Creep tests on this material were reported previously by Kanter and Spring (Proceedings A. S. T. M. Vol. 30 Pt. I, 1930, page 110). The test at 550° F. gave a clearly-marked endurance limit at 39,000 lbs./in.², well above the 30,000 lbs./in.² found in room temperature tests. At 800° F. the endurance limit was not determined, fracture occurring in 100 million cycles at 2500 r. p. m. at 28,000 lbs./in.². Under these conditions at 200 r. p. m. fracture occurred in a few million cycles. Time occupied by the endurance test rather than the number of the cycles of stress seemed to determine failure. At 1200° F. fractures occurred at 6000 lbs./in.², in the endurance tests no endurance limit was obtained and time was again the important factor in failure rather than number of cycles. The stresses at which failure occurred at 800° and 1200° F. were higher than the stresses for 1% flow in 10,000 hrs. in a static creep test. It seems probable that at 800° F. or above, the criterion for failure is the rate of creep rather than the fatigue properties. Details of the apparatus and methods used are given. The work is not yet complete. HWG(6)

The Significance of Crystal Structure for the Evaluation of the Elastic Limit and Fatigue Strength of Elektron Metal. (Die Bedeutung des Kristallaufbaues für die Beurteilung der Elastizitätsgrenze und Dauerfestigkeit von Elektron Metal.) W. Schmidt. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 54–57.

It is pointed out that since Mg (or Elektron Metal) is hexagonal in structure its yield point will be much more affected by crystallite orientation than that of cubic metals. Unpublished research by E. Schmid and G. Siebel has shown that *the threshhold shearing stress for slip in a pure Mg single crystal is 0.116 kg./mm.²*. If, however, the metal lattice in the single crystal is so oriented that the plane of slip is perpendicular or parallel to the direction of tension *fracture without elongation takes place at 7–9 kg./mm.²*, a 4000–5000% greater tension. Upon elongation Mg thus slips at a low stress, but rapidly hardens until finally the strengthened crystallites are all similarly oriented for slip. The behavior of Al is fundamentally different, a difference of only 85% between easiest slip and fracture obtaining. Al possesses the possibility of slipping in several planes and thus but little reorientation on deformation is necessary to make the deformation nearly uniformly distributed among the crystallites. The tension-elongation diagram for Mg (Elektron Metal)—thus shows a low elastic limit with the stress rising rapidly from 6 kg./mm.² at the elastic limit to approximately 21 kg./mm.² at an elongation of 0.05% and slowly thereafter, whereas with Al (duralumin) the stress rises slowly from 17 kg./mm.² at the elastic limit to 21 kg./mm.² at an elongation of 0.05%, and thereafter runs parallel to the curve for Mg. It is pointed out that any chosen conventional limit of elongation for the yield point in these two metals is artificial and useless, and that the whole stress-elongation diagram should be considered. An example is given in the design of a turbine bracket wheel of Elektron Metal. The importance of fatigue and of the mechanical hysteresis loop is emphasized. Hysteresis loops are given for duralumin stressed in (static) tension and also in torsion (dynamic) and for Elektron Metal in torsion (dynamic) and for both duralumin and Elektron Metal in torsion (dynamic) after a preliminary bending fatigue. The Elektron metal shows a damping capacity (internal friction) greater than duralumin. RFM+EF(6)

Porter's Method for the Calculation of the Natural Vibration Frequency of Crank Shafts. (Verfahren von Porter zur Bestimmung der Eigenschwinungszahlen von Kurbelwellen.) K. Schlaefke. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 28, 1931, pages 404–405.

In order to reduce the usually rather tedious process of determining the torsional vibrations of crankshafts, Porter separates the shaft into few individual masses which are connected by massless pieces of the shaft or by pieces of uniform mass. The greater simplicity of this method as compared with the method of Wydler is illustrated by an example. Ha(6)

Methods of Testing. Proposed Definitions of Terms Relating to. F. B. Seely, Chairman, A. S. T. M. Sub-Committee on Elastic Strength of Materials. Appendix III to *Preprint* No. 4, Report of A. S. T. M. Committee E-1 on Methods of Testing, for June 1931 Meeting, *American Society for Testing Materials*, 3 pages.

Since a true elastic limit test, by the method of loading and releasing stress is seldom made, and the observed "proportional limit" depends on the sensitivity of the extensometer used, a new definition is proposed to bring out a method that will be universally applicable to the measurement of the property involved. The term "yield point" is to be abandoned for general use, since it applies only to materials that do have a sudden yield, like structural steel. Instead, the term "yield strength" is to be used, and the percentage of permanent set obtained at that load recorded. The terminology is to be, for example, yield strength (set = 0.1%) = 52,000 lbs./in.² Whatever value of set is adopted, it is to be stated. The yield strength may be obtained by plotting a stress strain diagram and drawing a line parallel to the elastic line, offset by the amount of set. The intersection of this line with the stress-strain curve shows the yield stress. If the nature of the material is known by prior tests, extensometers or dividers may be used for rough work. Umpire tests require the diagram. The elastic limit and proportional limit are limiting values of yield strength in which the set is not measurable, and hence, is considered to be zero. HWG(6)

Fourth Report of the Wire Ropes Research Committee. W. A. Scoble *Proceedings Institution of Mechanical Engineers*, No. 2, Mar. 1930, pages 553–602.

Large ropes are less efficient than small ones when tested under corresponding conditions. Compares 6-strand rope with 19, 24 and 37 wires per strand. On the largest pulley, of diameter 56.5 times that of the rope, there was little difference in performance. On smaller pulleys, the 6 × 24 was only slightly better than the 6 × 19, but the 6 × 37 showed a distinct superiority. More rapid bending of the rope does not reduce the endurance when the inertia effect of the pulley is eliminated. An increase in the length of rope bent, at least up to about 8 times the length of the lay is accompanied by a reduction of the number of bends which cause failure. Bending a rope through any angle over a pulley produces the same destructive effect until the angle of lap is reduced to 20° below which the endurance increases very rapidly. Accelerated elongation gives a warning of the approach of rope failure, but the indication is not always distinct with 6 × 37 ropes. Judged from the aspect of fatigue, all ropes show better performance on small pulleys than that indicated by the properties of the wire. On larger pulleys, the bending stress is reduced but the tension carried does not increase as rapidly as would be expected from consideration of fatigue alone. Present tests of wire are incomplete and unsatisfactory. Includes appendix and discussion. Results of tests made in Germany on the bending of wire ropes are given in the appendix. An account of these experiments appeared in *Zeitschrift Verein deutscher Ingenieure*, Mar. 20, 1929. RHP(6)

Speed of Tension Testing of Metallic Materials, Proposed Requirements for. J. H. Smith, Chairman, A. S. T. M. Sub-Committee on Effect of Speed of Testing. Appendix II to *Preprint* No. 4, Report of A. S. T. M. Committee E-1 on Methods of Testing, for June 1931 Meeting, *American Society for Testing Materials*. 3 pages.

Rate of application of stress in tensile tests up to the yield strength should be:

Structural Steel	24000 ± 5000 lbs./in.²
Monel Metal	2000 ± 5000 lbs./in.²
Brass and Copper	12000 ± 3000 lbs./in.²
Aluminum and Its Alloys	8000 ± 2000 lbs./in.²

Methods for determining the rate of increase of stress are described. HWG(6)

Recent Machines for Testing Vibrations. (Neure Schwingungsprüfmaschinen.) W. Späth. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Jan. 17, 1931, pages 83–85.

Vibration measuring apparatus exerts on the body, to be tested for vibrations, artificial periodic forces for which the point of attack, direction of attack, magnitude and frequency can be selected at will. The actions of these forces are recorded in resonance curves from which important characteristics, i. e., natural frequency, logarithmic decrement of damping, magnification factor, swinging mass, dynamic spring constant, etc., can be determined numerically. A few of such machines for the investigation of bridges, soil and other purposes are briefly described. 9 references are cited. Ha(6)

Good Selectivity Is Required for Magnetic Analysis. Sigfrid Spech (Ferrous Magnetic Corp.). *Steel*, Vol. 87, Dec. 18, 1930, pages 48, 50.

In magnetic analysis as usually conducted, much confusion arises from intermingling of the phenomena connected with the peculiarities of the apparatus for testing and those characteristic of the test specimen. Among the first can be mentioned the lack of coincidence between the theoretical and actually found-in-practice plane of the maximum magnetic flux, asymmetry in the angular relations between the axis of the coil and the lines of force, and non-symmetrical distribution of the magnetic characteristics on both sides of the center of the coil. By the use of several symmetrical induction systems strictly identical in their constants a considerable selectivity can be achieved in the separation among different observations permitting the identification in test specimens of grain size, the presence of segregations, non-metallic inclusions, cracks, seams, flows and other defects, as distinguished from stresses and strains. A hypothesis of the mechanism of testing is advanced. JDG(6)

The Determination of the Elastic Constants. (Die Bestimmung der elastischen Konstanten.) G. Berndt. *Zeitschrift für Instrumentenkunde*, Vol. 50, Nov. 1930, pages 624–638; Dec. 1930, pages 679–692.

The points covered are: (1) The Hertz definition; (2) Examination of the Martens mirror equipment; (3) Determination of the elongation λ', dilatation ϵ' and modulus of elasticity E with telescope and scale; (4) Determination of λ' and ϵ' with auto-collimation-telescope; (5) The immediate determination of the ratio of transformation; (6) Determination of the reduction of area with the instrument according to Sieglerschmidt; (7) Modified instrument applied; (8) Measurements on 9 steels (plain C, low Ni and Ni-Cr-steels and 18/8 Cr-Ni-steel); (9) Literature. EF(6)

Contribution to the Behavior of Materials Submitted to Dynamic Stress. (Beiträge zum Verhalten von Werkstoffen bei dynamischer Beanspruchung.) A. Esau & E. Voigt. *Zeitschrift für technische Physik*, Vol. 11, Mar. 1930, pages 78–81.

Refers to investigations on damping properties and on modulus of elasticity in dependence on temperature. EF(6)

Testing of Hardened Material and Enameled Pieces for Uniformity of Their Hardness and Quality of Surface Respectively by Cloud-Burst Test. (Prüfung gehärteter Werkstücke und emaillierter Gegenstände auf Gleichmässigkeit ihrer Härte bez. ihrer Oberflächenbeschaffenheit nach dem "Kugelregen"—Verfahren.) E. Franke. *Oberflachentechnik*, Vol. 7, Aug. 19, 1930, pages 151–153.

Not only the degree of hardness but also the uniformity of hardness is of great importance. The usual test methods of Brinell, Rockwell, scleroscope and the scratch method of Martens do not give a perfect indication as to the uniformity. A method by Herbert called cloud-burst test, permits testing the whole surface of the piece simultaneously. A great number of steel balls of 3 mm. diameter are dropped from a certain height onto the piece to be tested. With properly adjusted height dependent on the prescribed degree of hardness of the test material the test pieces remain perfectly undamaged while those of unsatisfactory hardness or showing soft spots are more or less roughened by the rain of little balls. The roughened places can be clearly recognized on the smooth background. The test lasts 1 to 2 minutes. The same test is very well suited also for enameled pieces; the height from which the balls are dropped is most appropriately about 1 to 1.5 m. without injury to the enamel. Several illustrations and a list of 5 references are given. Ha(6)

Magnetic Properties. Report of A. S. T. M. Committee A-6. T. Spooner, Chairman. *Preprint* No. 13 for June 1931 Meeting, *American Society for Testing Materials*, 8 pages.

The Committee is strongly opposed to the adoption of the series of magnetic units proposed by the U. S. Sub-Committee of the International Electro-technical Commission on February 16, 1931, in view of the confusion and complexity that would ensue, but favors its suggestion of the term "oersted" instead of "rowland" for the unit of magnetic force. A proposed method of alternating current test at low induction is appended. HWG(6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A. S. T. M. Research Committee on Fatigue of Metals.

Brittle Fracture in Metals. B. H. HAIGH. *Engineering*, Vol. 130, Nov. 28, 1930, pages 685–686; Dec. 5, 1930, pages 717–719; Dec. 12, 1930, pages 752–753.

From lectures delivered at King's College, Nov. 1930, under the auspices of the Armourers and Braziers Company of the City of London. Reviews various types of brittle fractures. Different types are discussed and illustrated by photographs. Brittle fractures are due to triple tension, manner in which material is loaded or to fatigue. When a metal is exposed to tension in three mutually perpendicular directions, failure occurs without warning. Reviews various tests best fitted to develop triple tension including the Erichsen test, notched-bar test, Docherty's variation of the notched-bar test, and a test of Dr. Schurinning for determining the effect of speed in notched-bar tests. Final lecture is discussion of brittle fractures due to fatigue. Reviews early methods of fatigue testing. Recent tests show that heating has little to do with development of fatigue but if temperature of bar steadily increases, ultimate failure results. Curve is given showing results of tests made to determine effect of chemical action on fatigue of brass. Other curves show results obtained with Cu-Ni alloys. LFM(6f)

High-Frequency Fatigue Tests of Light Alloy Sheet Material. Sub-Committee on Metals. 16th Annual Report, *National Advisory Committee for Aeronautics*, 1930, pages 37, 38.

Preliminary data are given on results with the novel air-driven high-frequency apparatus at the Bureau of Standards for endurance limits of light alloys. The specimens are tested in vibration at frequencies of 215 to 310 cycles/second. The number of cycles to which the tests were carried is not stated.

Symbol	Material	Endurance Limit lbs./in.²
MAH	Mg alloy with 4% Cu, 0.4% Mn, as rolled, longitudinal and transverse	5000–6000
2SH	Commercial Al, cold-rolled, longitudinal and transverse	10000
3SH	Al alloy with 1¼% Mn, cold-rolled, longitudinal and transverse	12000
17ST	Duralumin 4% Cu, ½% Mg, ½% Mn, quenched and aged, longitudinal	15000
25SW	Al alloy, 4½% Cu, 0.8% Mn, 0.8% Si, quenched and aged, longitudinal	11000
51SW	Al alloy, 1% Si, 0.6% Mg, quenched and aged, longitudinal	10500
51ST	Al alloy, 1% Si, 0.6% Mg, quenched and aged, longitudinal	13000

In the symbols H = hard rolled, W = aged at room temperature, T = maximum heat-treated temper. The typical tensile strengths are about as follows, in lbs./in.²

MAH	43000
2SH	24000
3SH	29000
17ST	58000
51SW	35000
51ST	48000

HWG(6f)

Endurance of Sand-Cast Light-Metal Alloys. (Die Dauerfestigkeit der Leichtmetall-Sandguss-Legierungen.) W. SARAN. Published by Pfeffer & Balzer, Darmstadt. 1931, 87 pages, 56 figures, 17 references.

Endurance limits of various sand cast light alloys were determined within what the author thinks to be ± 5% of the true value, in the usual rotary bending test, in repeated torsion, and in a tension-compression or axial loading test. For the last a Schenck machine operating at 30,000 cycles per min. was used. The rotary bending and the torsion tests were at 3000 cycles per min. Tests were carried to 30–50 million on rotary bending, but only to 20 million on the tensile-compression tests and only to about 15 million on torsion. The S-N curves are not plotted logarithmically and the reader will have to replot in order to form his own judgment as to whether a true endurance limit was approached. The discrepancy between the rotary and the tension-compression tests is not satisfactorily explained as, beside the type of test, the cycle frequency and the number of cycles to which the test was carried, were also different. Saran is apparently not very sure of the accuracy of his tension-compression results, stating that they depend on the assumption that the modulus of elasticity has been correctly determined by static test for use in calculating the dynamic test. Rise-of-temperature observations, after the Lehr method, were made, but gave results wholly at variance with the endurance data. Test bars were turned from 0.7″ or 0.8″ diameter castings. All were made in dry sand except K. S. See Wasser, alufont and elektron which were cast in green sand. The alufont was quenched from 490° in water and aged at room temperature. Beside the data given below, static bend and torsion tests and studies of the hysteresis loops on repeated torsion were made. All the endurance data agree in showing low endurance values for the heat-treated alufont, not withstanding its higher tensile strength, that the Mg alloy was superior to the Al alloys in endurance, and that, of the Al alloys, the 6% Cu alloy has the best endurance properties except for silumin in torsion. Saran concludes that none of the "accelerated" tests, rise of temperature, change in rate of deflection or change in power consumption, are of any value in endurance testing of these alloys.

The Static and Fatigue Properties of Brass. J. B. KOMMERS. *Preprint* No. 48 for June 1931 Meeting, *American Society for Testing Materials*. 14 pages, 1 figure, 5 tables, 2 references.

Tensile, compression, Rockwell hardness and rotary beam fatigue tests were made on 80–20, 70–30 and 60–40 brass. The first and last contained 0.09% and the other 0.02% Pb. All contained 0.02–0.03% Fe, and the last 0.01% Sn. They were tested in cold-drawn condition, annealed at 527° and 1100° or 1300° F. and after compressing 20% after the high temperature anneal. Endurance limits (number of cycles to which tests were carried not stated) ran from 21,000 to 30,000 lbs./in.² The best values were at the 527° F. draw, though on 80–20, the 1100° F. anneal was as good. 60–40 had the highest endurance limit. Though the tensile strengths are higher in the cold-drawn condition, and cold work increases the endurance limits, the increase is not proportional and the brasses can be over-drawn so that the endurance drops. Cold work followed by the 527° F. anneal gives best endurance. Endurance is not proportional to any static property in these materials and cannot be predicted. HWG(6f)

Fatigue Stresses with Special Reference to the Breakage of Rolls. FREDERIC BACON. *Proceedings South Wales Institute of Engineers*, Vol. 47, Apr. 10, 1931, pages 141–335.

The behavior of rolls is greatly affected by fatigue. The hair crack markings on the freshly fractured faces of a broken roll are fatigue fractures. The alternating fatigue limit of the gray Fe core of a good roll is about 5 tons/in.² just below the mottle. The limits of the mottle are possibly lower due to the composite structure. In a new roll, the outer surface of the chill carries the greatest stress. The fatigue limit of chilled or white cast Fe is about 8 tons/in.² A week's work is roughly equivalent to 20,000 stress cycles. The superposition of a constant torque (T) will make no difference on the fatigue life of a roll subjected to alternating bending moment (M) provided T/M (ultimate tensile strength/alternating fatigue limit) is less than 2. T/M for the leading bottom roll of a train of 4 mills is less than 1.3, therefore there should be no difference between bottom and top rolls. The major principal stress in the leading bottom roll of a train of 4 mills is 30% higher than in a top roll, therefore bottom rolls should fail first if this were the criterion of failure. Hair cracks may form and not spread unless a certain critical depth (about the thickness of chill on a new roll) is exceeded. A mathematical investigation of stress ratios in revolving beams of lenticular section when compared with the hair crack markings actually found on the fractured faces of broken rolls and shafts shows that hair cracks tend to terminate in elliptic curves of uniform crest stress ratio. Curves have been constructed enabling the stress ratios to be evaluated from the hair crack markings on broken rolls. The imperfect elasticity of cast Fe is not sufficiently pronounced at stresses up to ½ its tenacity to seriously invalidate the ordinary equations of elastic bending, permitting the use of such equations for calculating fatigue stresses. At stresses above ½ the tenacity, strain increases much more rapidly than stress and the stress-strain curve in tension bends over much more than the stress-strain curve in compression. Hence the neutral axis drifts to the compression side. Thus, the distribution of stress assumed in the ordinary formulae for elastic bending is widely departed from. The error is large, differs according to whether the section is round or rectangular and will vary with sponginess of the Fe and intensity of stresses. The modulus of rupture for round test bars varies between 1.8 and 2.0 according to the equation $M_r = 1.1\ u + 9.5$ tons/in.² For cast irons of medium strength (the modulus of rupture on square bars/the modulus of rupture on round bars) = 0.89. For a given gray cast Fe the strength falls off with increase of section provided the smallest section shows no sign of chill. A 30-in. roll may be 3 times stronger but break under ½ the deflection of a 20-in. roll. An extensive bibliography is appended. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 80. AHE(6f)

Requirements of the Repeated Impact Test. (Zur Frage der Beanspruchung Beim Dauerschlagversuch.) S. BERG. *Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, Verein deutscher Ingenieure*, No. 331, 1930, 28 pages, 53 figures, 15 tables, 82 references.

Mathematical and experimental study of the actual stresses, and the distribution of stresses in notched bars for repeated impact testing, with different types and depths of notches. The notch factor is also studied by a model consisting of a pile of rubber sheets into which projections are pressed, corresponding to the shape of the notch. The deformation of the layers of rubber is thought to give some indication of the stress distribution in a bar with that shape of notch. An interesting table shows, for a 0.14% C steel, cold worked to 0, 5, 9, 13 and 17% reduction, unannealed and annealed at 140°, 210°, 280°, 350° and 420° C., the number of blows to fracture on the repeated impact test, and the area of the final fracture, left after the advancing cracks from each side had progressed up to final fracture, and compares these figures with the notch toughness calculated from that final area and the work required to break it, and with notch toughness determined by single blow impact in the usual manner. Strengthening against repeated impact (number of blows required) increases, in unannealed material, as cold working increases but then decreases on the annealed specimens as the annealing temperature rises to 350° C. on the specimens reduced 5% and 9%, and to 280° C. on those reduced 13% and 17%. It then rises at the higher temperatures. The single blow impact test shows the final rise in all but the specimens with 9% reduction, but the dip in the curve is less marked than on the repeated impact test. HWG(6f)

Fatigue Strength of Carbon- and Alloy-Steel Plates as Used for Laminated Springs. R. G. C. BATSON & J. BRADLEY. *Engineering*, Vol. 131, Mar. 20, 1931, pages 405–406.

Condensed from paper read before the Institution of Mechanical Engineers, Feb. 20, 1931. Conditions of surface layer of spring steel plates cause fatigue resistance of complete laminated springs to be lower than mechanical properties of material would indicate. Fractures of laminated springs may be due to very low limiting ranges of stress obtained from unmachined plates compared with those from machined specimens. Deleterious layer could be removed by machining 1/16 in. from the surface. "Surface effect" was found to be produced by hardening and tempering. Only very slight improvement was obtained by heat treating spring plates after a thin layer had been machined from the surface of the rolled material. Tables are given summarizing results of tests made. LFM(6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Production of Electrolytic Iron Printing Plates. C. T. THOMAS & W. BLUM. *Metal Cleaning & Finishing*, Vol. 2, July 1930, pages 597–598.

From paper presented before American Electrochemical Society, May 29–31, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 796. MS(7a)

Purification and Analysis of Alkali Cyanides. M. R. THOMPSON. *Bureau of Standards Journal of Research*, Vol. 6, June 1931, pages 1051–1059.

Alkali cyanide is an essential constituent of solutions used to electroplate with certain metals, including gold, silver, copper, cadmium, zinc and their alloys. This paper summarizes the results of other investigators on the laboratory preparation of alkali cyanides of high purity, and considers several volumetric methods which have been used for the analysis of the product. Particular attention is given to the titrations with mercuric chloride (Hannay), nickel sulphate (Lundell) and silver nitrate (Liebig-Deniges). In the present work, potassium and sodium cyanides were synthesized from liquid hydrocyanide acid and the appropriate hydrogen or ethoxide in ethyl alcohol solution. No difficulty was found in thus producing potassium cyanide of high purity, but the sodium cyanide was always less pure. This difference was traced to the reactions and solubility relations for potassium and sodium salts in ethyl alcohol. Methyl alcohol was found to be suitable for recrystallizing cyanides in certain cases, as the alkali salts are more soluble in it. When applied to the potassium cyanide, the silver nitrate (Liebig-Deniges) method of analysis was found to be the most accurate. WAT(7a)

Commercial Control of Silver Plating. A. E. THURBER. *Monthly Review American Electroplaters' Society*, Vol. 18, Jan. 1931, pages 4–17.

Paper with discussion. A general discussion of the control of plating as it is affected by the properties of the base metal, by the finishing operations of forming, grinding, buffing and polishing. A method is described for testing the paper used in packing for sulphur content since even as low as 0.0004% is liable to form silver sulphide tarnish. The factors for insuring uniformity and high efficiency are discussed and the influence of racking or wiring arrangement is pointed out. In the discussion, some practical points are brought in comparison with European practice. Ha(7a)

Plating on Radiator Shells. OLIVER P. WATTS. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, page 1060.

Abstract of paper read before the American Electrochemical Society See abstract in *Metals & Alloys*, Vol. 1, Dec. 1930, page 912. MS(7a)

The Deposition of Bright Zinc-Cadmium Alloys from Cyanide Baths. C. J. WERNLUND. *Monthly Review American Electroplaters' Society*, Vol. 17, Dec. 1930, pages 4–9.

The brightest and most pleasing deposits are obtained with anodes containing from 8 to 15% cadmium. A preferred bath concentration is:

$Zn(Cu)_2$	75.0 g./l.	or	10 oz./gal.
NaCN	37.5 g./l.	or	5 oz./gal.
NaOH	90.0 g./l.	or	12 oz./gal.
CdO	3.0 g./l.	or	0.27 oz./gal.

under the following operating conditions:

Anodes	8 to 15% Cd, balance Zn
Anode current density	6 to 10 amp./ft.^{2}
Cathode current density	13 to 60 amp./ft.^{2} (20 to 40 preferred)
E. M. F.	1 to 3 as required
Cathode current efficiency	90 to 100% (based on Zn)

The deposit is a successful rustproof coating and has a very great resistance to corrosion. It can also be deposited on malleable and cast iron and adheres well to steel. Ha(7a)

Silvery Platings. H. WHITEHEAD. *Product Engineering*, Vol. 2, Apr. 1931, page 171.

An entirely silver-like finish on smaller articles such as jewelry, household appliances, etc., can now be obtained by plating with palladium or rhodium, or with a co-deposition of nickel and cobalt, or by platinum. The metals of the platinum group are particularly resistant to tarnishing since their melting point is high. Ha(7a)

Some Theoretical and Practical Aspects of Cadmium and Zinc Plating. S. WERNICK. *Preprint, Electroplaters' and Depositors' Technical Society*, London, Apr. 15, 1931, pages 129–152; *Metal Industry*, London, Vol. 38, May 22, 1931, pages 531–533; June 5, 1931, pages 579–581.

The intrinsic protection against corrosion of iron and steel is greater in the case of zinc coating as compared with cadmium coating. But the rate of sacrificial corrosion of the coating is much less in the case of cadmium, making the latter more durable. Cadmium and iron are so close in the electromotive series that under certain conditions the protection provided is negligible. The color of zinc deposit from sulphate bath is superior to that from cyanide bath. The color of cadmium deposit is whiter. Due to the ductility of cadmium deposit it retains protective value when subjected to mechanical treatment. But cadmium is softer than zinc, and therefore has less resistance against abrasive wear. Due to its ready oxidation, cadmium is not suited as a base for japan and enamel finishes. The reaction of cadmium to 14 common chemicals is considerably less than that of zinc. Corrosion tests conducted in sodium chloride and ammonium chloride media indicate that there exists a minimum thickness of cadmium deposit which will provide satisfactory protection. A point of inflection is found on the curve connecting thickness of deposit with durability which suggest a minimum thickness of 0.0002" for rust prevention, and 50% more is recommended for practical applications. Aside from thickness, the cadmium deposit must be fine grained which is obtained only by accurate control of bath composition and plating conditions. Following are recommended for the bath: Cadmium content 3%, free cyanide 100% over the combined cyanide, alkali content 1.5 to 3%, current density not over 15 amp./ft.^{2}, temperature not over 30° C. PRK+LCP(7a)

Production Nickel Plating at Low pH. C. E. CLINDININ. *Monthly Review, American Electroplaters' Society*, Vol. 18, Mar. 1931, pages 11–24.

The author gives the results of his experience with the General Spring & Bumper Corporation. Among the advantages of plating at a low pH: (1) price saving because nickel as anode is cheaper than nickel sulphate; (2) easier to obtain anodes of a given high purity than is the case with nickel salts; (3) cost of handling is lower. Discussion brought out a great number of practical questions. MFB(7a)

A Silver-White Alloy Plate. COLIN G. FINK & KIHOUGH H. LAH. *Monthly Review American Electroplaters' Society*, Vol. 18, Jan. 1931, pages 29–34.

A silver-white cobalt-nickel alloy can be deposited by the proper selection and arrangement of the nickel and cobalt anodes. The cathode was of brass. The experimental work is described. The whitest plates were 55 to 75% Ni and 45 to 25% Co. The hardness test gave 250 Bierbaum units for alloys from 100 to 25% Co. The corrosion was found to be least for about 50% cobalt, with a loss of 0.51 mg./in.^{2} See also "The Deposition of Nickel-Cobalt Alloys," *Metals & Alloys*, Vol. 1, Dec. 1930, page 910. Ha(7a)

The Economical Heating of Plating Vats by Gas. *Metal Industry*, London, Vol. 38, May 22, 1931, pages 525–526.

For economical heating of vats, improved burners of large heating capacity should be used and vats should be placed in brick settings. PRK(7a)

Electrolysis. (Elektrolyse.) P. GERHARDT. *Oberflächentechnik*, Vol. 7, Sept. 2, 1930, pages 161–162; Sept. 16, 1930, pages 171–173; Oct. 7, 1930, pages 181–182; Oct. 21, 1930, pages 191–192.

The purpose of electrolysis is to disintegrate, by means of an electric current, an electrically conductive solution such as the watery solution of an acid, a base, or a salt, or a molten liquid; to dissociate them by discharge of its positive and negative components. The conductivity depends on the mutual mobility of the molecules and the disintegration products of the latter as well as on the temperature. The behavior and dissociation phenomena are explained in general and illustrated by a few more or less complex electrolytes. The electrical units for electrolysis are explained; it is shown how current and dissociation voltage can be calculated. A table of dissociation voltages for a number of electrolytes is given. Nernst's law for the e.m.f. required for a metal to pass an ion from its surface into the solution is explained; the anodic phenomena and normal potentials are discussed; and the influence of temperature explained. The more recent reviews on the nature of electrolysis seem to replace the older dissociation theory of Ostwald (because of its failure for strong electrolytes) by a new equilibrium theory. This equilibrium must exist in the system between the ions on one side, on the other between the ions and the agglomeration formed by them. This view was corroborated, to a certain extent, by the recently acquired knowledge of the nature of ions. The solution molecules are under the influence of exterior electric fields and interact with the ions according to their mutual charge and their distance. Ha(7)

Chromium Plating of Tools and Gages. LT. WILLINK. *Monthly Review American Electroplaters' Society*, Vol. 18, Apr. 1931, pages 32–44.

Some practical information on chromium plating at the Frankford Arsenal. Chrome plating of tools and gages has resulted in great savings. Ha(7)

Chromium Plating, Its Application in the Ceramic Industry. HARRY C. WOLFE. *Ceramic Age*, Vol. 16, Dec. 1930, pages 315–317, 322–323.

The author distinguishes between lustrous plating of a thickness of 0.000005 to 0.00001 in. and hard plating for wear and resistance to abrasion of 0.003 to 0.005 in. In the ceramic industry, hard plating of mixers, glass collecting rods, pump plungers, dies, etc., increases their life many times. Ha(7a)

How to Plate Aluminum Die Castings. HAROLD K. WORK (Aluminum Co. of America Laboratories). *Metal Progress*, Vol. 19, Apr. 1931, pages 68–70.

The author describes methods of plating aluminum base die castings with various metals and their applications. WLC(7a)

High-Output Nickel Baths and Conversion of Old Nickel Baths to Higher Output. (Hochleistungs-Nickelbäder und Umstellung alter Nickelbäder auf höhere Leistung). *Oberflächentechnik*, Vol. 7, Dec. 2, 1930, pages 223–225.

For very high current densities (10 amp./dm.^{2} and more) the bath must operate under increased metal contents and temperature and, besides, moving of the cathode and stirring of the electrolyte becomes necessary. Means for obtaining this end are described. The working temperature should be 60° C. The proper ratio between concentration, temperature and density is of great importance. For fast deposits, the danger of formation of pores exists and this prevents the formation of the homogeneous covering necessary for protection against corrosion. The changes to be made in the old baths to obtain higher outputs are discussed. Proper concentration is given for high outputs, 35–40 kg. nickel salt for each 100 l. Ha(7a)

Galvanic Metal Deposition with Superposition of Alternating Current. (Galvanische Metallabscheidung mit Wechselstromüberlagerung.) GALVANICUS. *Oberflächentechnik*, Vol. 7, Nov. 4, 1930, pages 201–214.

Certain experiments have been made recently to determine the effect of an alternating current on the deposition of metal when it is superimposed on a direct current. It can be stated that such superposition has a depolarizing effect. The alternating current reduces the anodic and cathodic polarization and the electro-chemical passivity. This action is illustrated by the example of nickel-plating. The superposition of alternating current resulted, here, in a much more uniform deposit with a less changeable structure. The mechanical properties were better than when deposits were made by direct current. Microscopic examination revealed certain differences between deposits in chloride and sulphate electrolytes; these are discussed at length. The reduction of the cathode polarization in chloride solutions for a ratio of d. c. to a. c. of:

1: 2 amounts to about 0.10 volt
1: 4 amounts to about 0.18 volt
1:10 amounts to about 0.22 volt

For sulphate solutions, the effect is about the same. This method also makes the use of pure nickel anodes possible while with d. c., impure anodes are necessary because pure nickel is not dissolved fast enough. The superimposed a. c. improves the dissolution so that pure metal can be used. This method may become especially useful for alloy deposits. Tests with nickel-zinc alloys showed a greatly increased nickel content in the deposited material with increasing ratio of a. c. to d. c. The respective test curve is reproduced. This method has found a wider industrial use in the electric refining of gold where the a. c. has to improve the solution at the anode. In conclusion, it is said that this process gives good promise for industrial application, although at present the laboratory stage is not fully overcome. Ha(7a)

Acetamide and Formamide as Solvents for the Electrodeposition of Metals. L. F. YNTEMA & L. F. AUDRIETH. *Journal American Chemical Society*, July 1930, pages 2693–2698.

Zinc, cadmium, lead, tin, cobalt and nickel were deposited electrolytically from solutions of their salts in formamide. Current densities were of the order of 0.02 to 0.04 amp. /cm.^{2} and temperature 100° C. The same metals and also thallium were deposited from acetamide solutions under similar conditions. Metals higher than zinc in the e. m. f. series were not deposited from solutions in either solvent. MEH(7a)

The Use of Brighteners in Plating Solutions. JOE HOEFER. *Monthly Review, American Electroplaters' Society*, Vol. 18, June 1931, pages 23–29.

Includes discussion. Paper before Chicago branch of American Electroplaters Society, Annual Meeting, January 1931. Most brighteners used in plating baths are colloids which act as an elastic membrane around metal ions in the baths. This membrane prevents deposition of large groupings of metal ions with the result that the crystals in the cathode deposit are small. This membrane also causes cathode polarization, although polarization itself has no direct bearing on crystal formation at the cathode. Experimental data are given to show that small amounts of glue and cadmium chloride increase the voltage of sulphate copper bath and nickel bath, respectively.

Bath	Brightener	Concentration mg./l.	Bath Voltage	Cathode Current Density amp./ft.^{2}	Character of Deposit
Sulphate Copper	Glue	0.0	0.76	21	Large crystals
		0.1	0.82	21	Small crystals
		0.2	0.83	21	Small crystals
Cold Nickel	Cadmium Chloride	0.0	1.9	10	Fine crystalline
		0.1	2.0	10	Smooth, fine crystalline
		0.15	2.2	10	Smooth, fine crystalline
Hot Nickel	Cadmium Chloride	0.0	2.5	35	Crystalline
		0.15	2.8	35	Finer crystalline

LCP(7a)

The Treatment of Cyanide-Alkali Baths in Electroplating. (Ueber die Behandlung cyankalischer Baeder in der Galvanotechnik.) Laboratory of Langbein Phanhauser Works in Leipzig. *Oberflächentechnik*, Vol. 8, Jan. 20, 1931, page 13.

The above company is one of the leading electroplaters in Germany and has the following suggestions to offer in regard to handling cyanide-alkali baths. First of all, in preparation and regeneration of bath, the use of cheap double salts must be avoided because they contain large amounts of potassium or sodium. If they are used, the current efficiency is not only impaired but also the quality of copper coating, due to the excessive amount of hydrogen evolved at cathode. Whenever potassium or sodium carbonate happens to be present in large amounts, the new bath must be made up, or they can be readily removed in cold winter days by allowing the bath to cool 5° C. below zero. The deposited crystals of sodium carbonate can then be removed by iron shovels. Second, cast anodes must be used; whenever rolled anodes are used, they must, prior to service, be thoroughly annealed. Third, if there is an abundant development of anodic slime in the brass or copper bath, the excessive use of ammonium chloride must be avoided. ER(7a)

Plating Household Specialties. C. L. Etchison (Everedy Co., Inc.) *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, pages 693–696.

Deals with the procedure of the Everedy Co., Inc., Frederick, Md., in burnishing, tumbling, polishing, cleaning, and Ni, Cd, Cu and brass plating articles such as strainer sets, screen door grilles, bottle cappers, siphon fillers, etc. MS(7a)

Deposition of Nickel-Cobalt Alloys. C. G. Fink & K. H. Lah. *Metal Cleaning & Finishing*, Vol. 2, Oct. 1930, pages 867–868.

From paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 910. MS(7a)

Electrodeposition of Nickel and Chromium on Zinc Die Castings. Samuel Gordon. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 765–766.

Castings are polished to a very good, non-porous surface and are cleaned electrolytically by immersion in a good commercial cleaner for 15 sec. at 1500° F. They are rinsed in cold H_2O and flash plated in a brass solution containing 1 gal. H_2O, $4^1/_3$ oz. NaCN, 3 oz. $Cu(CN)_2$, 1 oz. $Zn(CN)_2$, 2 oz. Na_2CO_3, and 1 qt./100 gal. solution, NH_4OH. If Ni is to be deposited directly, the parts are cleaned, rinsed and dipped in 20% HF. After rising in H_2O, the articles are plated for 4–5 min. at 800° F. in a bath consisting of 1 gal. H_2O, 6 oz. $NiSO_4$, 2 oz. $NiSO_4.(NH_4)_2SO_4$, 4 oz. NaCl, 2 oz. $MgSO_4$, 2 oz. $Na_2SO_4.10H_2O$, and 1 oz. H_3BO_3. Solution should have pH of 6.8. Articles are then rinsed in cold and hot H_2O, dried in sawdust and color buffed. They are then Cr plated for 3–5 min. at 90° F. using a c. d. of 75 amp./ft.^{2}, in a bath containing 1 gal. H_2O, 48 oz. CrO_3, 1 oz. $Fe_2(CrO_4)_3$, and $^1/_2$ oz. C. P. Na_2SO_4. They are washed in cold and boiling H_2O, dried at 200° F. and color buffed. MS(7a)

Electroplating Automobile Bumpers in a Full Automatic Plating Machine. J. M. Mayers. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, page 722–724.

Describes a machine in which the bars are suspended horizontally. The anodes are bent to approximately the same curvature as the bumper, thus giving even current distribution. The bumpers are held in the rack inclined at about a 45° angle with the face of the bar toward the anodes. About half of the vertical parts of the anodes are above the bumpers. Only a 24 in. lift is necessary in the transfer mechanism. A tank only 36 in. deep is required. MS(7a)

Gold Solutions. O. Sizelove. *Monthly Review American Electroplaters' Society*, Vol. 18, Apr. 1931, pages 45–50.

Three methods of depositing gold are described and the compositions of the electrolytes given: the cyanide method, the salt water method and the immersion method. For obtaining green gold, largely an alloy of gold and silver, sometimes cadmium, a cyanide bath is operated at 95° to 100° F. White gold is obtained by adding nickel to the cyanide gold solution, and copper for 14 carat gold. Rose gold solutions are fine gold solutions with an addition of caustic soda or potassium carbonate. Ha(7a)

Chrome Plating in Patent Literature. (Die Verchromung in der Patentliteratur.) R. Justh & F. Markhoff. *Oberflächentechnik*, Vol. 8, June 2, 1931, pages 118–124.

A complete tabulation of patents dealing with chrome plating in America, Germany, Austria, Great Britain, France and Switzerland, without regard to the practical value of the patent. Patents since 1852 are included. They are arranged in the order of the date of their application and are subdivided thus: (1) electrolytes based on chrome acid; (2) chromium electrolytes based on low-valency compounds of chromium; (3) melt electrolysis; (4) deposition of chromium alloys; (5) anodes; (6) anodic pretreatment; (7) thermal treatment; (8) intermediary coatings; (9) miscellaneous methods; (10) covering of the baths; (11) miscellaneous devices; (12) chrome plating of quantity articles; (13) application of chrome plating. A commentary on the importance of some of the patents is added. Ha(7a)

Design for Electroplating. G. Soderberg. *Product Engineering*, Vol. 2, June 1931, pages 262–264.

Suitable design for articles which are to be plated in full automatic plating machines is of particular importance. Points which must be watched are depth of hollows, shape of inside corners and projecting parts, shielding of one part by another, elimination of gas pockets, proper draining, method of hanging on hooks or immersing and stability of suspension. Ha(7a)

Electrodeposition of Iron-Nickel Alloys from Cyanide Solutions. Lawrence E. Stout & Jonas Carol. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, page 946.

Abstract of paper read before the American Electrochemical Society See *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. MS(7a)

Introduction of Iron into Alkaline Cleaning and Plating Solutions. E. J. Liscomb. *Monthly Review American Electroplaters' Society*, Vol. 18, Jan. 1931, pages 17–29.

Paper with discussion. The reason for numerous failures of steel plating tanks has been investigated. The tank should never be made the anode of the circuit because eventually corrosion is sure to follow. Caustic soda, soda ash or sodium cyanide, when used as a cleanser, will cause no trouble as long as there is no salt such as sodium sulphate, trisodium phosphate, sodium chloride or ammonium chloride present. Work which is pickled in hydrochloric acid or any other acid should be well neutralized and rinsed several times in clean water before going to a plating solution. Cleaning and alkali plating solutions should be free from all chlorides or the tanks should be rubber lined. Another line of useful suggestions is added. Most of them are corroborated in the discussion. Ha(7a)

The Electrochemical Behavior and the Dissolution Speed of Single Crystals of Zinc in Sulphuric Acid. (Das elektrochemische Verhalten und die Auflösungsgeschwindigkeit von Zinkeinkristallen in Schwefelsäure.) M. Straumanis (University of Riga). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 147, Apr. 1930, pages 161–187.

Potential measurements in neutral and acid zinc sulphate solutions and dissolution speed of single crystals of Zn in acids. EF(7a)

Theory of Dissolution of Metals. (Zur Theorie der Metallauflösung. Zugleich Antwort an die Herren Thiel & Eckell.) M. Straumanis (University of Riga). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 148, June 1930, pages 349–380.

The theory of the difference effect is summarized and some conclusions are drawn therefrom. EF(7a)

Practical Use of the Electromotive Series in Electrodeposition and Separation of Metals. J. J. Mulligan. *Monthly Review American Electroplaters' Society*, Vol. 18, Apr. 1931, pages 5–8.

A discussion of faulty conditions during plating which may be due to electrolytic trouble, too high voltage, temperature, concentration or some other condition. Most of these can be controlled by proper consideration of the electro-chemical order elements. Ha(7a)

Electrometallurgy (7b)

Electrolytic Extraction of Tin and Copper from Bronze Scrap. (Extraction electrolytique de l'etain et du cuivre des dechets de bronze.) O. Scarpa. *Bulletin de la société Française des Electriciens*, Vol. 10, May 1930, pages 572–579.

Scrap bronze is melted in a reverberatory furnace and cast into anodes which are electrolyzed in sulphate solution for the recovery of Cu in the usual manner. The solution is continually purified from colloidal SnO_2 by passing it through heating tanks. The slimes containing all Sn in the form of oxides are converted into stannates which are chemically purified and converted by electrolysis into a very pure Sn sponge which is then melted. JDG(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Crystal Forms of Galvanizer's Dross and Zinc-Iron Alloys. Wallace G. Imhoff. *Iron Age*, Vol. 126, Dec. 18, 1930, pages 1853–1854; Dec. 25, 1930, pages 1932–1934.

Crystals are classified under 6 systems. Fe and Zn are found in isometric or cubic system and the hexagonal system. The temperature and amount of components present affect the crystal form of the alloy and its chemical composition. Zn heated to 900° F. for 6 hrs. and slowly cooled did not show any dross or Zn-Fe alloy. Pure Zn heated to 950° F. showed traces of both Zn-Fe alloys and dross. Dross crystals are characteristically long and slender. Alloy action of Zn begins at melting point of Zn. As temperature is raised, alloying action on Fe becomes stronger. Dross crystals pack tightly when heated. Dross consists of the melt and the Zn-Fe alloy crystals. As temperature increases, the Zn-Fe alloy appears to lose Zn. Crystal system changes completely at higher temperatures. Fe content increases with rising temperature. Results show that such alloys as $FeZn_3$, $FeZn_5$ and $FeZn_7$ are not present in ordinary galvanized coatings but are rather Zn-Fe alloys formed at higher temperatures. VSP(8)

Bendability of Galvanzied Coatings. (Biegefähigkeit von Zink-Ueberzügen.) Heinz Bablik. *Zeitschrift für Metallkunde*, Vol. 22, May 1930, pages 171–173.

See *Metals & Alloys*, Vol. 2, Jan. 1931, page 8. EF(8)

Sprayed Aluminum Coatings. Leopold Pessel. *Metal Industry*, London, Vol. 38, Mar. 13, 1931, page 228.

When rolled aluminum sheet is exposed to salt water spray, the surface is pitted and in addition elongated, blister-like exfoliations appear in direction of rolling. Tests showed that spraying the sand-blasted surface with molten aluminum prevented such exfoliations. PRK(8)

Hot Galvanizing with Zinc and Cadmium. (Die Feuerverzinkung und Feuervercadmiung.) K. Sch. *Chemiker-Zeitung*, Vol. 55, Mar. 25, 1931, pages 225–226.

About half of the total production of Zn is used for galvanizing iron and steel. The parts should be pickled in 10–20% warm H_2SO_4 or cold HCl for $^1/_2$ to 2 hours to remove scale. The Zn is melted in an iron pot, evenly heated by gas, oil or coke. The temperature should be as low as possible to prevent alloying of Zn and Fe, which is objectionable. The Zn should be reasonably pure, with Pb not over 1.6% and Fe not over 0.08%. From $^1/_4$ to 3% Al is sometimes added to increase fluidity. The Zn is covered with a mixture of NH_4Cl and glycerin to protect it against oxidation. With the Zn at 430° to 490° C. the articles are immersed in it for several minutes, withdrawn, and the excess Zn shaken off. Galvanizing with Cd is done in the same way except at about 360° C. Fe does not interfere as it does not alloy with Cd. Cd coating is softer than Zn. Dipping in 17% Zn and 83% Cd at 300° or in 29% Cd and 71% Zn at 220° produces good results, especially for exposure to CO_2 and NaCl. CEM(8)

"Zinc Slinger" Aids Galvanizing. *Brass World*, Vol. 27, Apr. 1931, page 84.

A machine for removing excess zinc from metals which are galvanized by the hot immersion method is offered by N. Ransohoff, Inc., Cincinnati, O. It has aided in improving the appearance of the galvanized pole line hardware, while making for greater efficiency in production at the plant of Hubbard & Co., Pittsburgh, Pa. The first section is a slanting hooded perforated metal barrel, gas heated. The barrel revolves at 50 r. p. m. The excess zinc is removed and reclaimed in a chute beneath the hood. Parts travel into a larger drum, revolving slowly in water. This quenches, but does not cool, and the zinc is set. The finished parts are discharged and dry of their own heat, resulting, it is claimed, in a better finish, elimination of surplus zinc on threaded work, increased production and lower costs. WHB(8)

Effects of Various Gases in the Kiln on Burning of Bright Gold for Gilding Ceramic Wares. A. Nakatsuchi. *The Journal of the Society of Chemical Industry*, Japan, Vol. 34, Feb. 1931, pages 67B-69B.

Sulphur dioxide, hydrogen sulphide, hydrogen and carbon dioxide are injurious gases for burning of bright gold; the best atmosphere is nitrogen gas containing a little oxygen, but the process is not practicable. Moisture does not affect the decomposition of bright gold. MB(8)

Metal Coatings (Metallische Ueberzüge). E. Liebreich. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Apr. 25, 1931, pages 529–530.

Chemical, physical and mechanical resistivity of metal coatings are discussed in general and a brief description given of different methods of coating. Ha(8)

Galvanizing Pots, Their Material and Construction. F. Hausmann. *The Pure Iron Era*, Vol. 3, No. 11, 1930, pages 14–17.

Of all steels tested for loss of material in molten, pure iron, Armco Ingot Iron, showed the lowest loss figure. The pots are welded by water gas or oxy-acetylene. A thickness from 25 to 40 mm. according to the size of the container is desirable. Several large tanks are illustrated. Ha(8)

The Surface Treatment of Aluminium and Its Alloys. *Foundry Trade Journal*, Vol. 44, Apr. 30, 1931, pages 301–302; May 7, 1931, pages 329–331.

An article based on information published by the British Aluminium Company, Ltd., on methods available for treating the surface of aluminum with a view to its decoration or protection. Mechanical processes of surface treatment are dealt with, and chemical methods are very completely described. Methods of plating also receive some consideration. OWE(8)

On the Determination of the Thickness and the Quantities of Coatings on Galvanized Iron. (Ueber die Bestimmung der Dicke und der Eigenschaften der Schutzschichten auf galvanisiertem Eisen.) Vondracek. *Korrosion und Metallschutz*, Vol. 5, Sept. 1930, page 206.

Refers to a paper presented before the International Congress for Mining, Metallurgy and Applied Geology, 1930. EF(8)

INDUSTRIAL USES & APPLICATIONS (9)

Finishing Stainless Steels, Pickling, Polishing and Welding. C. C. SNYDER (Republic Steel Corp.). *Metal Progress*, Vol. 19, Feb. 1931, pages 77–80.

Classification of stainless materials is made, applications to exposed parts of motors cars and decorative purposes in buildings are discussed. The properties of one class, the 16–20% Cr and 7–10% Ni alloys, are given and discussed in detail. Welding and structural applications of this alloy are described. Pickling solutions and polishing methods are discussed. WLC(9)

Relation between Welded-on Overlays and Heat Treatment. MILES CATLIN SMITH (Stoody Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1160–1176.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The possibilities of economies in machine construction with proper combination of welded overlays as well as diminished wear in service are described and discussed. WLC(9)

Steel for Good Welding. W. E. STINE (Lincoln Electric Co.). *Power Plant Engineering*, Vol. 35, July 1, 1931, page 710.

Alleges that proper steel for welding should have a certain balance among Mn, Si and Al, in relation to carbon content. This is shown in curves. The allowable Al runs in a straight line from 0.001% at 0.1% C to 0.005% at 0.5% C. Manganese runs from 0.15% at 0.1% C to 0.66% at 0.30% C, thence to 1.2% at 0.40% C. Silicon runs from 0.01% at 0.10% C to 0.045% at 0.40% C, and thence to 0.07% at 0.55% C. HWG(9)

Ship Building and its Relation to the Steel Industry. H. G. SMITH (Bethlehem Shipbuilding Corp.). *Preprint* for May 1931 Meeting, *American Iron and Steel Institute*, 26 pages.

Traces growth of use of steel in ships. Mass production is seldom possible as each ship is specially designed. All forming and fabrication is best done at the shipyard. Total annual demand for iron and steel products in American shipbuilding and repair is about 36 million dollars. Needs of the industry are for workable steels of higher tensile strength, highest possible modulus of elasticity and lowest possible coefficient of thermal expansion. High steam pressures and the requirements of the Diesel engine both call for better materials to withstand high temperatures and high stresses. HWG(9)

Use of Aluminum in the Decorative Arts. (Verwendung von Aluminium im Kunstgewerbe.) CLEMENS SIMON. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 238–249.

A collection of photographs showing the extensive use of aluminum furniture especially in hospitals, accessories for windows, doors, etc. Ha(9)

Welded Cranes. (Geschweisste Krane.) H. SCHMITT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 23, 1931, pages 652–653.

Discussion of advantages of welding over riveting in cranes and of the best methods of joining parts and their testing. Some illustrations are included. Ha(9)

Aluminum in the Brewing Industry. (Aluminium in der Brauerei-Industrie.) SIEPKE. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Nov. 1930, pages 177–190.

Aluminum of a purity of 99.3% to 99.5% is fully resistant to the ingredients used in beer brewing; also, the taste is not changed so that storage tanks of aluminum are as good as wooden tanks. The fermentation process was not influenced by the greater heat conductivity of the metal as against wood. The disinfectants used to-day are described and their degree of eventual toxicity and their action on aluminum are discussed. Only activin and formaldehyde may be used for disinfection of aluminum apparatus. The latter part of the article deals with the equipment of breweries for which aluminum can be used; how tanks should be dimensioned; what advantages accrue from its use; how aluminum tanks should be transported; and how the ratio of price per 100 l. changes with the tank dimensions. Ha(9)

Autogenous Cutting of Springs. (Autogenous Schneiden von Federn.) O. SCHEH. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 28, 1931, page 392.

Springs have been made by cutting a helical opening in a pipe or solid steel block. Tests showed that, axially and tangentially, no difference in strength exists; a subsequent treatment is not necessary. This method is superior to that of winding a steel rod around a mandril, especially if the inner and the outer diameter are widely different. These autogenously cut springs were made by Siemens-Schuckertwerke and used for coupling machines. Ha(9)

Steels Used in Ford Industries. J. L. MCCLOUD. *Metal Progress*, Vol. 19, Mar. 1931, pages 32–39, 83.

Methods of classification, storage and differentiation between a large number of steels are described with a chart showing the markings given, properties and analysis. Heat treatment of various parts are discussed. Applications are discussed for Cr, Mn and CrNi steels. Fatigue applications of case carburized parts are described. WLC(9)

Metal Toys Look Real. JOHN MAPES. *Metal Progress*, Vol. 18, Dec. 1930, pages 33–39.

Describes methods of manufacture of various metal toys. Variety of metals, production methods and engineering design essential to production of a good line of metal toys are discussed. WLC(9)

Diverse Metals in Huge Terminal. J. W. LOVE. *Metal Progress*, Vol. 19, Jan. 1931, pages 33–38.

Description of the new Union Terminal Station in Cleveland and its many applications of metals. WLC(9)

Manganese Steel has Many Functions. W. A. LONGDEN. *Edgar Allen News*, Vol. 9, Apr. 1931, pages 845–849.

Illustrations of coal cutters, steel buckets, tractor links, gravel pump castings, etc., made of a special manganese steel by Edgar Allen & Co., Ltd., Sheffield, England. Ha(9)

The Relation of Steel to Agriculture. W. D. LAUFER. *The Steel Maker*, Vol. 2, No. 1, pages 45–47.

An enumeration of the very varied articles and implements used at present by farmers. The quantities of steel necessary to their production are considered. Ha(9)

Die and Roll Steels for Brass Mill. H. G. KESHIAN (Chase Companies). *Metal Progress*, Vol. 18, Nov. 1930, pages 75–80.

Uses of wrought iron, high chromium iron and cast iron for such applications as stirring molten metal, thermocouple protection tubes and ingot molds are described. Steels used in rolls, cold shears, drawbench chains and cold drawing dies are discussed. Hot working steels are discussed under the headings, general requirements, types of steels, hot piercing, hot forging and extrusion. Suggested compositions of steels are given for the various applications discussed. WLC(9)

High Pressure with Steel Castings. WM. H. JACOBI. *Product Engineering*, Vol. 2, June 1931, page 245.

Pump cylinders and similar parts are made by the Keokuk Steel Casting Co. of a carbon steel with 0.275 to 0.3% C; tensile strength of 75,000 lbs./in.^{2}; elastic limit, 41,000 lbs./in.^{2}; elongation 27%. Steels of a tensile strength of 200,000 lbs./in.^{2} are obtainable. Ha(9)

Old Ornamental Ironwork Embodies Traditions of Early Days. MARY WILLIS SHUEY. *Steel*, Vol. 87, Oct. 23, 1930, pages 47–49.

Description of some examples of early Spanish, French and American ornamental ironwork of cast-iron and wrought-iron in the Vieux Carre district of New Orleans. Suggests adaptation of corrosion-resistant steels for such decorative work. MS(9)

Neglected Bridge and Highway Guards Offer Opportunities for Steel Products. *Steel*, Vol. 87, Sept. 18, 1930, pages 23–25.

Discusses the necessity for making bridge and highway guards safe for modern traffic, and shows how steel products are suited for this purpose. MS(9)

Aluminum Alloys Widely Used in Traveling Cranes. *Steel*, Vol. 87, Aug. 28, 1930, pages 52–53.

Describes crane of 10-ton capacity built by the Northern Engineering Works for the sheet mill of the United States Aluminum Co. at Alcoa, Tenn. Span is 76½ ft. between truck wheels. Lift of hoisting hook is 25 ft. Bridge is of latticed-type girder construction and is made of No. 17 ST Al alloy rolled sections. Trucks are No. 195 Al alloy castings. The trolley, electrical fittings and many other parts are also made of Al. Total weight with trolley is 30,000 lbs. Made of steel it would weigh 77,100. MS(9)

Chrome Steel Doors Guard Wall Street Securities. *Steel*, Vol. 87, Aug. 28, 1930, pages 46, 56.

Vaults and vault doors are made up of cast-steel, 5-ply Cr steel, hardened and drill proof, open-hearth steel, infusite (a Cu-Fe alloy possessing high torch-resisting qualities) hard chemical plates and polished finish plates. MS(9)

Large Uses of Steel in Small Ways. *Steel*, Vol. 87, July 10, 1930, page 52; July 24, 1930, page 48; Aug. 7, 1930, page 52; Aug. 21, 1930, page 59; Sept. 4, 1930, page 62; Sept. 18, 1930, page 64; Oct. 2, 1930, page 54; Oct. 16, 1930, page 58; Oct. 30, 1930, page 60; Nov. 13, 1930, page 65; Nov. 27, 1930, page 54; Dec. 11, 1930, page 64; Dec. 25, 1930, page 52.

Deals with cotter-pins, bell-buoys, lightning-arresters, jacks, engine foundations, time-recorders, traffic markers, picks, industrial lighting reflectors, water-towers, miniature golf, access units and cameras. MS(9)

The Welded Siemens-Betz Propeller Fan. (Der geschweisste Siemens-Betz Schraubenlüfter.) *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 76–77.

The whole fan (except motor) with housing is made up of welded parts. Ha(9)

Alloy Steels Here to Stay. *Railway Age*, Vol. 87, Nov. 30, 1929, pages 1299–1300.

A general review of the use of alloy steels such as chromium, vanadium, nickel and nickel-chromium for locomotive forging boiler tubes, etc. VVK(9)

Steel Castings as Machine Parts. R. A. BULL. *Machine Design*, Vol. 3, May 1931, pages 37–40.

Desirability of full coöperation between designer and foundryman is emphasized. Some inherent weaknesses in castings due to incorrect design are cited and illustrated and suggestions are offered for improvement in the finished part. Ha(9)

The Modern Ornamental Iron Worker and Gas-Welding. (Der moderne Kunstschlosser und die Gasschmelzschweissung.) H. CASSE. *Die Schmelzschweissung*, Vol. 10, Apr. 1931, pages 89–90.

It is shown how artistically gas-welding can be applied in ornamental iron work. Ha(9)

Aluminum Alloys Containing Nickel. W. C. DEVEREUX. *Brass World*, Vol. 27, Feb. 1931, pages 31–35.

The manufacture and application of "Y" and "RR" alloys are outlined. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 39. WHB(9)

Wrought Iron Boilers for Hot Water and Low Pressure Steam Heating Plants. (Schmiedeeiserne Heizkessel der Warmwasser- und Niederdruckdampfheizungen.) E. KALISCH. *Die Schmelzschweissung*, Vol. 10, Mar. 1931, pages 58–60.

The advantages of wrought iron for boilers are discussed and a few examples described. Ha(9)

Alloy Forgings Have Wide Application. A. L. HAMILTON (Midvale Co.). *Steel*, Vol. 87, Dec. 11, 1930, pages 43–46.

Most of the large solid and hollow alloy steel forging development has been confined to the oil, power, chemical and pressure process industries. Tabulates many of the applications of the past 10 years. Many compositions are available, the approximate analyses of the steels that are melted, cast and forged, machined and heat-treated by the Midvale Co., being tabulated. Principal alloying elements are V, W, Cr, Ni and Mo. Forgings of C steel still have a place, particularly in many industries where early obsolescence of design is met. The Midvale Co. uses 50–85 ton open-hearth and 100, 500 and 1000 lb. Ajax-Northrup high-frequency furnaces. MS(9)

Principal Metallurgical Products Used in the Aeronautical Construction. (Principaux produits metallurgiques utilises dans la construction aeronautique.) G. R. HANNEL. *Aciers Speciaux, Métaux et Alliages*, Vol. 5, Dec. 1930, pages 550–558.

Most of the special steels used in aircraft contain: Ni, Cr, Si, Mo, W, Co, Al. Cr and Ni-Cr steels are preferably used for cylinders and for nitrided cylinders a Cr-Al or Al-Cr-Mo steel is used. A 14% W or high Cr steel is used for valves. Most of the light alloys used are Alpax, "Y," and duralumin. GTM(9)

The Use of Non-Ferrous Metals in the Aeronautical Industry. D. HANSON. *Journal Institute of Metals*, Vol. 44, No. 2, 1930, pages 5–28.

See *Metals & Alloys*, Vol. 2, Apr. 1931, page 81. (9)

Hollow Steel Propeller New Development for Airplanes. W. G. GUDE. *Steel*, Vol. 87, Nov. 27, 1930, page 56.

Hamilton Standard Co. uses a tube for blades, while the Pittsburgh Screw & Bolt Corp. welds together 2 steel plates. The latter uses SAE 6130 Cr-V steel. New type of hub design eliminates considerable weight without loss of strength. Steel can be placed where greatest stresses occur in blade. Due to the stiffness of the steel blade near the tip, there is less distortion when in flight than in the solid metal blade. Ultimate strength of Cr-V steel is 100,000 lb./in.^{2}, respectively, for age-hardened Al alloy. Most of the pitting and erosion now encountered in seaplane service with Al alloy blades will be eliminated. MS(9)

Rolled Steel Floor Plates are Finding New Uses. E. C. KREUTZBERG. *Steel*, Vol. 87, Sept. 18, 1930, pages 56–57, 59.

Describes installations of floor plates in buildings, boiler-houses, factories, bridges and the railroad field. MS(9)

Steel Is Accepted Material for Hangar Construction. K. B. LANSDOWNE. *Steel*, Vol. 87, Dec. 4, 1930, pages 61–62.

Steel hangar has become standard in the aviation industry. Problems encountered are in the field of design. Principal problem is that of neutralizing or avoiding wind pressures while placing aircraft in their stowage places. Describes several recently built structures. MS(9)

World's First Metal-Base Highway Built of Pure Iron. TRUMAN L. FLAT. *The Pure Iron Era*, Vol. 3, 1930, pages 4–5.
An experimental stretch of highway near Springfield, Ill., was paved with a metal base of Armco Ingot Iron of 10 gage corrugated sheets welded on each end and twice on each side. A mastic sand cushion is laid on the iron base and then bricks laid, rolled and asphalt filler applied. Ha(9)

Uses of Aluminium in Shipbuilding. PAUL V. FARAGHER. *Engineering*, Vol. 130, Dec. 19, 1930, page 770.
Abstract of paper read before the American Society of Naval Architects and Marine Engineers, Nov. 1930. For general use on ships, alloy is recommended which contains Cu 4.0, Mn 0.5 and Mg 0.5%. Most effective coating for preventing corrosion is Al paint made by adding Al bronze powder to a vehicle such as oil varnish. LFM(9)

Welded Aluminum in Tank Trucks. W. M. DUNLAP. *Welding*, Vol. 2, June 1931, pages 384–385.
The use of aluminum alloy instead of steel is of enormous advantage in transporting and delivering. The lighter weight makes a greater capacity possible, so that in spite of the price being about double that of steel, about $20 per day is saved which balances the initial loss in about 150 days. Tests and the choice of materials are discussed. Ha(9)

Metallizing the Airplane. H. V. THADEN. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, 1930, *Aeronautical Engineering*, pages 167–172.
Includes discussion. The paper gives advantages and disadvantages of metal construction for airplanes. See "More Metal Being Used in Planes," *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. (9)

Saving Tonnage in Cruisers. LEWIS H. FAWCETT (U. S. Naval Gun Factory). *Metal Progress*, Vol. 19, Apr. 1931, pages 39–43.
The author describes the application of light alloys and stronger materials of lighter section to the construction of naval ships resulting in substantial savings in weight. Use of aluminum paint results in an appreciable saving in weight. WLC(9)

Improvements in Welding Technique for Pipe Lines in the Building Trade. (Schweisstechnische Neuerungen für Rohrbau im Baugewerbe.) P. THELEN. *Die Schmelzschweissung*, Vol. 9, Aug. 1930, pages 189–192.
Some applications of welding in sewer, water and gas lines in buildings are illustrated which permit a better adaptability to the available space and also a saving in space. Ha(9)

Recent Hand Work in Iron. (Neuzeitliche Handarbeiten in Eisen.) C. TUPHOLME. *Die Schmelzschweissung*, Vol. 9, Sept. 1930, page 217.
A few artistic decorations, chandeliers, etc. Ha(9)

Copper Pipe for Water Lines. (Kupferrohr für Wasserleitungen.) Contribution from the German Copper Institute. *Metallwirtschaft*, Vol. 10, June 5, 1931, pages 461–464.
The advantages of copper over steel pipe for drinking water and hot water lines are described. They include freedom from rusting, greater resistance toward chemical attack from the soil and sand, better resistance against breakage due to freezing on account of high ductility of copper, lower resistance to the flow of water on account of freedom from rust. For these reasons pipes of smaller diameter and wall thickness can be used and the cost of copper pipe becomes less than iron. Connections made by hard soldering or brazing offer no difficulties. CEM(9)

Homes of Metal. *Metal Progress*, Vol. 20, July 1931, pages 89–94.
Development of the use of metal in domestic construction is described and discussed. WLC(9)

Unusual Steel Flooring Designed for Saving Weight. *Iron Age*, Vol. 127, April 2, 1931, page 1089.
Describes pier constructed by the Erie Railroad in Weehawken, N. J., carrying 3 stories of storage and warehousing facilities on a foundation designed for only 2 stories. Pier is a steel frame, fireproof structure of 739 ft. by 97 ft. wide, supported on untreated timber piles. A complete description may be found in a recent issue of *Railway Age*. VSP(9)

Use of Acetylene Welding in the Construction of Automotive Street-Cleaning Vehicles. (Anwendung der Azetylenschweissung beim Bau von automobilen Strassenreinigungs-Fahrzeugen.) WILLENBACHER. *Autogene Metallbearbeitung*, Vol. 23, Aug. 15, 1930, pages 250–253.
A few illustrations of vehicles built by Keller & Knappich, Augsburg. Ha(9)

Aluminum Foil Tried on Car Roof. C. P. WESTLAKE. *Electric Railway Journal*, Vol. 75, Mar. 1931, page 153.
The tops of trolley cars were covered with 0.004" aluminum foil, applied with a foiling adhesive painted on the canvas top. Service since August 1930 indicates complete satisfaction as regards weather resistance, and a cooling effect in reducing the effects of the sun's rays. WHB(9)

Prospects of the Copper Industry. WILLIAM A. WILLIS (Copper & Brass Research Association). *Mining Congress Journal*, Vol. 17, Jan. 1931, pages 6–7.
Points out modern trend for using copper in building and exterior construction. Illustrates internal and external applications already installed in German buildings. DTR(9)

Steels for American Automobiles, Model 1931. J. M. WATSON (Hupp Motor Car Corp.). *Metal Progress*, Vol. 19, Feb. 1931, pages 33–37.
A paper presented before the Western Metal Congress in San Francisco, Feb. 16, 1931, and to appear in greater detail with discussion in the Transactions. After suggesting the advantages of a small number of different steels in an automobile, the author discusses under the headings of various parts of a car the steels specified for such parts. Ten important parts of the automobile are discussed at length with specifications as to composition and heat treatment for their production. Some 60 steels and their applications are mentioned. WLC(9)

Uses of Nickel. A. J. WADHAMS. *American Metal Market*, Vol. 37, June 6, 1930, pages 3, 4.
An outline. WHB(9)

Reducing Wear at Base-Metal Contacts. J. R. TOWNSEND. *Bell Laboratories Record*, Vol. 9, Nov. 1930, pages 124–126.
The fairly rapidly wearing brass terminals and brushes of a dial telephone apparatus were replaced by a 5% tin-phosphor-bronze which resulted in a five-fold improvement. Ha(9)

A New Oil-Less Bearing Metal. W. C. WILHARM. *Electric Journal*, Vol. 27, Sept. 1930, page 553.
A self-lubricating bearing metal with a life 10 times that of previous "oil-less" bearings has been developed. It should find application where bearings are used which require short-time operation and infrequent attention as in starting mechanisms. It depends for its low coefficient of friction upon the soap it contains. Powdered metals, such as copper, lead and zinc are thoroughly mixed with some fatty acid. Exceedingly high pressures and elevated temperatures, used in the molding process, result in the formation of a solid metal which is not porous and presents a good surface for an oil film to form and be maintained on. This new material is still in the development stage, but obviously has interesting possibilities. WHB(9)

HEAT TREATMENT (10)

Heat Treatment in Fused Salt Baths. W. J. MERTEN. *Houghton's Black & White*, Vol. 3, May 1931, pages 11–12.
General remarks on the possible chemical reactions between bath and steels whereby gases are formed which diffuse through the metal. Really neutral heating in gases is still an unsolved problem. Ha(10)

Heat Treatment Adds Mileage to Rolled Steel Wheels. R. W. STEIGERWALT. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 37–39.
The Carnegie Steel Company has developed "rim-toughened wheels," using a special heat treatment consisting of heating the wheels to the proper temperature to refine the grain and then rotating the rim of the wheel in water and immediately tempering it to take out any possible strains. Microphotographs show the structure. Ha(10)

Report of Committee A-4 on Heat Treatment of Iron and Steel. *American Society for Testing Materials, Advance paper* No. 12, June 23–27, 1930, 2 pages.
The committee recommended that tentative definitions of terms relating to heat-treatment operations, especially as related to ferrous alloys (A 119–28 T), be slightly revised as indicated. It was also recommended that definitions as revised be advanced to standard. (10)

Heat-Treatment of Grey Cast Iron. R. WHITFIELD. *Foundry Trade Journal*, Vol. 42, June 19, 1930, pages 455–457, 459.
Includes discussion extracted from paper before Sheffield section of Institute of British Foundrymen. Three general types of heat treatment used for gray cast iron: (1) Heating at low temp. (not over 540° C.) to relieve internal strains; (2) heating above critical range to relieve strains and increase machinability; and (3) heating above critical point followed by an oil quench. Contains discussion of the heat treatment of various Fe castings, pearlite Fe, soaking and cooling and batch type casting annealing furnace. VSP(10)

Some Phases of Heat Treatment of Cylinder and Alloy Irons. F. J. WALLS & A. HARTWELL, JR. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Mar. 1931, pages 865–896.
Tests were run to determine the relief of stresses in cylinder irons on heating to temperatures of 750° to 1150° F. The hardness of the irons as affected by air, water and oil quenching was investigated. Maximum relief of stresses is obtained with minimum growth and change in hardness by heating to 950° F. followed by slow cooling. Similar tests were made on Cr-Mo and Cr-Ni-Mn cast irons. CHL(10)

Heat Treatment of Railroad and Street Car Rails. (Les traitements thermiques des rails de chemins de fer et de tramways.) H. VITEAUX. *Revue de Métallurgie*, Vol. 28, Apr. 1931, pages 209–225.
To the Neuves-Maisons and Hagondange processes for heat treatment of rails described before (*Revue de Métallurgie*, Feb. 1926 and Jan. 1927) could be added Chadrine process in which the head of rails is sprayed with water from a long narrow slit, Duisburg process which does not present anything new (*Stahl und Eisen*, Oct. 1927), Maximilian Hütte method in which the head of rails is immersed in rapid stream of water and Kenney method used by Bethlehem Steel Co. where the rails leaving the shears are quenched for 30 sec. in water and immediately after placed into a drawing furnace kept at 850–1000° F. To these can be added the usual heat treatment of already cooled rails which was tried many times with complete success but was abandoned on account of the cost. For the usual composition of rails the sorbitizing treatment produces an increase in elastic limit and tensile strength of about 30–40% and a decrease in elongation of about 15%. Their impact value is increased. In case of Maximilian Hütte treatment the head of rail becomes martensitic to the depth of about 10 mm. with corresponding loss in ductility, which is still amply sufficient for impact specifications. Repeated impact test made on treated and untreated rails made of the same ingot and subjected to Neuves-Maisons process showed 3493 and 10,766 impacts, respectively. This represents an average of 25 rail heats. Stanton-Cambridge machine with a sharp notched test bar was used. Reports available from New South Wales railways show the wear of sorbitized rails to be about one-half of non-treated. Victoria railways report much longer life of the treated rails. Japanese State railroads have figures showing a 20% longer life for treated rails. French data show that while on normal track the difference in performance between treated and untreated rails is slight, in the areas where much braking and sliding takes place the former are much better. In one case a wear of 12-14 mm. in 3 years and 9 months for untreated rails was reduced to one millimeter in 10 months for treated. Treated rails do not have any particular resistance to cracking, but those already cracked show a better resistance to fracture than the untreated. Their advantage increases proportionally to the severity of the conditions under which a rail is working. Crushing of head is beneficially affected by increased elastic limit, i. e., by heat treatment. A large series of experiments conducted on French Northern railroads is not completed but already shows that the rails, even perfectly sound and not brittle, are susceptible to transverse fissures which are produced by sliding of wheels; thermal treatment appears, if not to eliminate them, at least to reduce considerably the speed of their propagation. (After presentation of the paper and before its publication these experiments were completed substantiating entirely the above expressed views.) JDG(10)

Hardening (10a)

Modern Tool Steels. J. A. HOPKINSON. *Automobile Engineer*, Vol. 19, Dec. 1929, pages 499–500.
Discusses the possibilities of error in the working of tool steel. High speed steel for tools should be hardened at 1300° to 1340° C. Steels containing from 5 to 10% Co require the higher temperature. Tempering should be done about 600° C. for 20 min. Co improves the wearing qualities especially when used at red heat. C should range from 0.65 to 0.80% depending upon the use of the tool. Diamond alloy steel contains 1.30 to 1.40% C, 5% W and small percentages of Cr and V. It is hardened in water at 800° to 810° C. Discusses production of dies and proper uses of tool steels. RHP(10a)

Metal Surface Hardening. A. E. SHORTER. *American Machinist*, Vol. 73, Nov. 22, 1930, pages 186E-189E; *Iron & Coal Trades Review*, Vol. 121, Nov. 14, 1930, page 725.
See *Metals & Alloys*, Vol. 2, May 1931, page 103. (10a)

Standardizes Process of Hardening Screws. J. W. MARSHALL. *Iron Age*, Vol. 126, Dec. 25, 1930, pages 1923–1924, 1977.
Five outstanding facts in maintenance of uniformly heat treated products are: the steel used; temperature of each treatment to be the same; length of time the work is in the furnace; time work is in the air; and temperature of cooling medium to be always the same. Gas is used as heating medium. Each charge is weighted before being put in the furnace. Charges run for about 90 min. at temperature of about 1650° F. and it is held within 10°. Oil is used for quenching. Work is drawn and tempered to temperatures up to 1200° F. in electric Homo furnace. After heat treatment, the work is Rockwell tested. This procedure is followed at the plant of the Allen Mfg. Co., Hartford, Conn. VSP(10a)

Annealing (10b)

Fundamentals of Copper Wire Annealing. O. S. HASKELL. *Wire & Wire Products*, Vol. 6, June 1931, pages 220–222.

The paper gives the results of experiments of the General Electric Co. to determine the furnace which is best suited for annealing copper and for obtaining a clean, non-oxidized product requiring no pickling or wiping. Continuous furnaces, batch-type furnaces, hood furnaces and Kenworthy furnaces are discussed and production data is cited. Ha(10b)

Electrical Annealing Installations in the Metal Industry. (Elektrische Glühanlagen in Metallwerken.) K. TAMELE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 28, 1931, pages 383–387.

The various forms of electric resistance furnaces, as they have been developed for heat treatment of metal products are briefly discussed and their operating properties explained. Descriptions are given of several examples of furnaces for pre-heating aluminum, brass plates for annealing of brass ribbons and wire coils. The factors determining the selection of furnaces are discussed. They include safety of operation, heat insulation, capacity of furnace, energy for heating up and type of furnace. It is shown that electric annealing is more economical, the more it is used in a plant. Ha(10b)

Case Hardening & Nitrogen Hardening (10c)

Carburizing with Propane. O. J. WILBOR & J. A. COMSTOCK. *Metal Progress*, Vol. 1, Oct. 1930, pages 99–100.

Paper presented before the 12th annual convention A. S. S. T. The reactions of the various gases H_2, CO, CO_2, O_2, N_2, steam and the hydrocarbons on steel are considered. The application of propane (C_3H_8) to carburizing, particularly by the "intermittent surge" method is described. Propane is admitted to the retort from a pressure source for a few seconds followed by a quiescent period of several minutes. Alternate purges of wet CO_2 can be used if desired to oxidize the soot and prepare the steel surface for further absorption of carbon. WHK(10c)

Recent Developments in Gas Carburization. O. J. WILBOR & J. A. COMSTOCK (Peoples Gas Light and Coke Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 533–551.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The authors discuss the use of city gas in carburizing, bright annealing and heat treatment of steel. An intermittent surge method of carburizing is described and its merits discussed. Data obtained by this method are tabulated. The method may be used to obtain any character of case desired. WLC(10c)

Nitriding of Iron and Iron Alloys. *Foundry Trade Journal*, Vol. 44, Apr. 30, 1931, page 312.

An abstract of an article by W. Eilender and O. Meyer (*Archiv für das Eisenhüttenwesen*) dealing with results of experiments carried out with electrolytic iron, four carbon steels, and a series of alloy steels—chromium, 14.51%; molybdenum, 8.16%; aluminum, 7.50%; and vanadium, 3.0%. The effects of temperature of treatment, time of treatment, etc., were considered and are dealt with in the article. OWE(10c)

Association of German Industrial Engineers. (Arbeitsgemeinschaft deutscher Betriebsingenieure. Mechanische Oberflächentechnik.) *Oberflächentechnik*, Apr. 7, 1931, page 82.

An abstract from the transactions of the meeting of the Association of German Industrial Engineers held on Jan. 22, 1931, in Berlin. In discussing the mechanical treatment of surface of steels, Ing. Prachtl brought out a new surface hardening process termed the Double-Duro-Process and developed by German tool steel makers. According to the process, the acetylene gas from a high pressure producer is mixed with oxygen and directed as a wide flame, 6–8 mm. long, against the steel object. The latter coming into contact with flame is immediately quenched by cool water sprayed on it through the 2 nozzles located under the burner. The depth effect is dependent upon the velocity of rotating the object. Especially suited for this process are steels containing carbon, chromium, molybdenum and silicon. ER(10c)

Correct Carburizing Practice. H. C. DECKARD. *Houghton's Black & White*, Vol. 3, Jan. 1931, pages 18–23.

Describes the manner of hardening a few pieces having complicated shapes. Ha(10c)

Nitriding the Larger Forgings. J. H. HIGGINS (Camden Forge Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 523–532.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The author describes and discusses the application of nitriding to large forgings. WLC(10c)

Case Hardening versus Nitriding. GEO. M. ENOS. *Modern Machine Shop*, Vol. 3, May 1931, pages 16, 20, 22, 24, 26, 28, 30.

The 2 processes are defined as follows: Case hardening is the process of carburizing and subsequent hardening, by suitable heat treatment, of all or part of the surface portions of a piece of iron-base alloy. Nitriding is the process of heating an iron-base alloy in contact with a source of nitrogen at a temperature such that the nitrogen content at or near the surface of the steel will be materially increased, thus securing great surface hardness. The 2 methods and the equipment necessary for each method are described. The structure of the metals is shown in microphotographs. Tables show which of the methods should be employed for a given alloy, how to heat treat it and what can be obtained by it. Ha(10c)

The Modifying Action of Ferrosilicon upon the Carburizing Process. E. G. MAHIN & F. J. MOOTZ. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 552–583.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion and 23 references. The restraining influence of ferrosilicon is further checked. Elementary silicon, magnesium-silicon and ferroboron act in the same way. Addition of silicon to the surface layers is shown. Ferro-silicon removes H_2S which is thought to act as a catalyzer of the carburizing reaction. In discussion the author states that the influence of H_2S was only observed late in the investigation and more data must be obtained to clear up the question of the influence of this gas. WLC(10c)

Carburizing for Depth. J. B. NEALEY. *Industrial Gas*, Vol. 9, Mar. 1931, pages 10–12.

The Tool Steel Gear & Pinion Co., Cincinnati, Ohio, uses a special method for carburizing steel parts up to 3000 lbs. to depths from $^3/_{16}$ to $^1/_4$ in. The modern installation for handling of alloy and low carbon steel is described. Ha(10c)

Carburizing with Gas in Underground Retorts. W. F. MCNALLY (New Process Gear Co.). *Metal Progress*, Vol. 19, Jan. 1931, pages 39–43.

The disadvantages of solid carburizing in equipment overhead, handling charges and space are enumerated. Experiments with the use of gas started in rotary retort using first city gas and later air-propane mixtures are reported. Air-propane mixture of 60% to 40% gave desired results illustrated by micrographs. Additional micrographs illustrate the cases obtained using city gas, natural gas and solid compound. By completely dehydrating city gas and maintaining 15 lbs. gage pressure in the retort successful carburization was obtained. A battery of pit furnaces with a heat exchanger for heating cold charges from the waste heat of previously carburized work is described. The advantages of this method of carburizing are reported. WLC(10c)

Relation of Structure to Surface Hardness of a Case Hardened Steel. H. W. MCQUAID & O. W. MCMULLAN. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 584–600.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Included discussion. The authors report on the non-agreement of file hardness with other hardness tests on carburized material. A study of the influence of the condition of the carbide is reported. It is shown how, at will, file hardness and low Rockwell, or vice versa, can be produced. In discussion A. L. Boegehold confirms this failure of file and other tests for hardness to agree on carburized work. WLC(10c)

The Nitriding Process. *Vancoram Review*, Vol. 2, Apr. 1931, pages 47–50.

Nitriding steels containing Al and Cr are the common types, but rough surfaces and poor transverse properties come with the use of Al. Use of Mo improves the ductility of the case, and avoids temper brittleness of the core so that Mo is now a regular constituent. A steel without Al, but containing 8% Cr, $1^1/_2$% Si and 0.70% Mo is said to give good results, but is expensive. The low alloy Cr V steels (S. A. E. 6100 series) with 0.20 to 0.60% C give tough nitrided cases of 750–800 Brinell, and solve many engineering problems at a low cost. High C, high Cr steels with both Mo and V have a higher core hardness than the Al steels, and such nitrided steels are suggested for ball bearings, rolls and drawing dies. Some attention is being paid to nitriding for corrosion resistance (against other than acid conditions) rather than for hardness. HWG(10c)

Nitriding Steel Parts. *Automobile Engineer*, Vol. 20, Oct. 1930, pages 381–382.

Description of a furnace developed by Leeds & Northrup Co. This furnace is electrically heated. RHP(10c)

The Structure of the Case in Cyanide-Hardened Steel. W. HENNINGER & H. JURICH. *Engineering Progress*, Vol. 11, Nov. 1930, pages 297–298.

The presence of eutectoid and needles can be detected in straight low-carbon steel treated in the cyanide bath for 5 hr. and cooled slowly when etched with hot concentrated sodium picrate solution. See also *Metals & Alloys*, Vol. 2, Feb. 1931, page 40. RHP(10c)

Modern Case Hardening Practice. F. W. ROWE. *Journal West of Scotland Iron and Steel Institute*, Vol. 38, 1931, pages 27–42; *Heat Treating & Forging*, Vol. 17, Apr. 1931, pages 372–373.

A résumé of the case hardening practice is presented. The subjects discussed are: (1) the choice of steel for case hardening, (2) "abnormality" in case hardened steels, (3) the case hardening of carbon steels, (4) the case hardening of alloy steels, (5) furnaces for case hardening, (6) compounds, (7) heat treatment after carburizing, (8) quenching media, (9) nitrogen hardening. Each subject is discussed in some detail, from a standpoint of elementary facts, as well as important facts to be remembered in successful case hardening. The article is too lengthy to abstract well; it should be consulted. WAT(10c)

Further Investigations in Nitriding. R. SERGESON & H. J. DEAL. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 474–501.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1931. Includes discussion. The authors in 3 sections discuss, first, container material with the conclusion that carbon steel enameled provides a low cost container of excellent properties; second, corrosion resistance, nitrided material is not resistant to acid action but is excellent for alkali, atmosphere, crude oil, ethyl gasoline, natural gas combustion products, tap water, and still salt water; and third, denitriding. Denitriding has been studied and is not so simple as suggested by Merten. In discussion the question of containers is further covered by J. H. Higgins (Materials Engr., Camden Forge Co., Camden, N. J.), J. P. Walsted, (M. I. T.) and A. B. Kinzel (Union Carbide). WLC(10c)

Nitriding in Packing Materials and Ammonia. A. B. KINZEL & JOHN J. EGAN (Union Carbide & Carbon Research Labs.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 459–473.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The application of inert packing materials such as magnesium, copper, and previously nitrided steel in ammonia nitriding is described. The advantages of shorter time for a given case depth, greater uniformity, and equally good results with chrome-aluminum and chrome-vanadium steels. In discussion Mr. Robert Sergeson, Republic Steel Corp., brings out the question of the time required for packing and for heating and cooling the greater mass of material (packing material). WLC(10c)

Quenching (10d)

The Selection of Quenching Media. H. J. FRENCH. *Houghton's Black & White*, Vol. 3, Jan. 1931, pages 4–7; Mar. 1931, pages 18–20; May 1931, pages 4–7.

In this series of articles, information is given and methods are discussed for the choice of cooling media, cooling rates, sources of variation in hardening, manner of cooling in liquids, critical cooling rates, carbon and alloy steels, manufacturing variables, size and shape of pieces to be treated, spray quenching and the control of flow in liquid baths. A great number of curves and tables illustrate the paper and supply practical data. Ha(10d)

A Note on the Formation of Nodular Troostite. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 19, Feb. 1931, page 88.

The writer reports results obtained by Mr. S. Sato with the self-recording dilatometer (described in January issue) offering an explanation for the formation of nodular troostite during the quenching of carbon steels. WLC(10d)

Aging (10f)

Hardness of Steel Changes with Age. Correspondence from E. W. EHN, Cannstatt, Germany. *Metal Progress*, Vol. 19, May 1931, pages 89–90.

Experiments and theories regarding precipitation hardening in steel are discussed. WLC(10f)

Recent Studies on the Aging of Aluminum Alloys. (Neuere Arbeiten über die Vergütung von Aluminiumlegierungen.) G. WASSERMANN. *Metallwirtschaft*, Vol. 10, Jan. 16, 1930, pages 47–49.

A review of the work of A. Portevin and P. Chevenard and of S. Kokuba and K. Honda on aluminum alloys published during 1930. CEM(10f)

Experiments on the Aging of Steel. (Versuche über das Altern von Stahl.) G. SACHS & W. STENZEL. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XVII, 1931, pages 38–45.

See *Metals & Alloys*, Vol. 2, Apr. 1931, page 82. (10f)

Artificial Age-Hardening of Duralumin and Super-Duralumin. (Die künstliche Alterung von Duralumin und Super-Duralumin.) K. L. MEISSNER. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, page 64.

Arrives at the conclusion that, by means of artificial aging, some physical properties of Duralumin and Super-Duralumin may be improved, as for instance the yield point, but only at the expense of other valuable physical properties, such as elongation, resistance to deformation, etc.

See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. EF(10f)

JOINING OF METALS & ALLOYS (11)

Metal Joints in Aircraft Construction. T. Watson Downes. *Welding*, Vol. 1, Aug. 1930, pages 663–667.

A brief description of welding, brazing and soldering one or more materials by different welding processes. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. Ha(11)

Brazing (11a)

Brazed Joints for Electric Conductors. Samuel Martin, Jr. *Electrical Engineering*, Vol. 50, June 1931, pages 434–436.

Electrical resistance brazing produces in electric conductors joints which possess several distinct advantages over equivalent soldered joints and can be made at a lower cost. The equipment and process are described and comparative figures between the 2 types of joints are indicated. WHB(11a)

Brazed Connections Improve Power Transformer Quality. E. M. Glenn (Westinghouse Elec. & Mfg. Co.). *Electric Journal*, Vol. 28, June 1931, pages 367–368.

Brazing replacement of soldering has resulted in an increase in electrical conductivity and mechanical strength of the connections and has reduced the size of the joint. Phosphor-copper melts at 700° C. and the heating of brazing causes removal of most of the phosphorus insuring excellent electrical conductivity. Several illustrations are included. WHB(11a)

Copper Brazing in Hydrogen Electric Furnace. H. W. Webber (General Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1144–1159.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The author discusses a process developed by General Electric Co. for copper brazing of tungsten carbide tips to nickel steel shanks. WLC(11a)

Soldering (11b)

Resistance Soldering of Hard-Metal Tools. (Widerstandslötung von Hartmetallwerkzeugen.) A. Fehse. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, June 6, 1931, page 708.

Description of a small device for soldering small pieces of hard-facing materials, cutting edges of tools, etc., to the carrying piece by heating it electrically. Ha(11b)

Soldering of Aluminum. (Das Löten von Aluminium.) L. Rostosky & E. Lueder. *Aluminium, Hauszeitschrift, V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 150–159.

The Deutsche Gesellschaft für Metallkunde has investigated the soldering of aluminum and established the following distinctions: Soft solders consist of alloy with Zn or Sn base and other low-melting heavy metals, such as Cd, Pb, Bi; they contain no, or very little, Al up to about 20%. The Al hard-solders contain at least 70% Al; the remainder is made up of Cu, Ni, Ag, Mn, Sn, Zn, Cd, Sb, Si, Ce, etc. The resistivity of such a joint against air, water and steam is very low. The methods of application are described in detail and examples of soldered pieces are illustrated. Hard soldering is of particular advantage for thin sheets and for cast pieces. The refinable Al alloys, lautal and scleron, and other artificially hardened Al alloys, however, cannot be hard-soldered nor welded because their strength is reduced by heating to the required temperature by 50% or more. When this method is applied, consideration must be given the problem of whether or not the remaining strength is sufficient for the purpose in question. A table of solders, their use, preparation of the pieces, testing methods for soldered joints and resistance against corrosion is added. See also *Metals & Alloys*, Vol. 2, Mar. 1931, page 70. Ha(11b)

Welding & Cutting (11c)

Automatic Arc-Welding of Thin Sheets. (Selbsttätige Lichtbogenschweissung von dünner Blechen.) W. L. Warner. *Die Schmelzschweissung*, Vol. 9, Sept. 1931, pages 200–201.

Taken from *Iron Age*, Vol. 124, 1929, pages 834–837. Ha(11c)

Welded Framework of Steel Pipes. (Geschweisste Fachwerkkonstruktionen aus Stahlrohren.) Rud. Ulbricht. *Die Schmelzschweissung*, Vol. 10, Jan. 1931, pages 4–6.

The advantages of using pipes in welded steel structures instead of profiles are pointed out by examples actually built and described. Comparing ordinary structures built of profiles with pipe structures, a saving of from 30 to 35% in weight and a reduction in surface of about 48% could be obtained. The latter feature is especially important for reduction of cost in maintenance by painting. Ha(11c)

Results of Recent Researches in the Field of Autogenous Welding. (Neuere Forschungsergebnisse auf dem Gebiete der Autogen-Schweissung.) E. Wiss & Ph. Pothmann. *Forschungsarbeiten auf dem Gebiete der Azetylen-Schweissung*, published by the Deutscher Azetylen-Verein, Jan. 1930, pages 7–25.

This work was undertaken to determine the influences on the quality of a weld due to chemical conditions such as purity of the gases used, physical conditions, i. e., flame temperature, temperature of the molten part, reactions on the burner as well as metallurgical phenomena occurring in welding, the human factor, the best method of testing welding pencil material. All these individual tests are tabulated and illustrated in micro-photographs. Details must be looked up in the paper since this is only the beginning of a quite general research. 24 references (German, English, American) are included. Ha(11c)

The Arc Welder's Accessories. James M. Vossler. *Modern Machine Shop*, Vol. 3, Feb. 1931, pages 52–62, 67.

Details that, while generally accorded scanty attention may account for important wastes or savings, are discussed. MFB(11c)

Production Engineering. (Editorial abridgement of paper by) N. F. Ward. *S. A. E. Journal*, Vol. 28, Feb. 1931, pages 240–241.

After engineer in charge has decided upon type of weld and heat treatment, next task is to supervise and to keep a check upon the welding machine and operator. Causes of failure and their remedy for welding operations of different types are discussed. Subjects covered are zones of the oxy-acetylene flame; electric-arc welding; resistance welding; temperature stresses in welds; annealing needed to preserve strength; temperatures for resistance welding. MFB(11c)

Welded Construction Applied to Special Machinery. D. V. Waters. *Product Engineering*, Vol. 2, Apr. 1931, pages 167–170.

Illustrations of a special large buffing machine, a wire-tinning machine and a tinsel-serving machine. Some points to be observed, particularly in sheet welding, are emphasized. The allowable load on fillet welds per linear in. is given:

Size of Fillet	Allowable Load
1/4 × 1/4 in.	2000 lbs.
5/16 × 5/16 in.	2500 lbs.
3/8 × 3/8 in.	3000 lbs.
1/2 × 1/2 in.	4000 lbs.
5/8 × 5/8 in.	5000 lbs.
3/4 × 3/4 in.	6000 lbs.

Ha(11c)

Sil-Fos
BRAZING ALLOY
(patent applied for)

MELTS AT 1300° F.

as compared with 1600° to 2100° F. for base metal brazing alloys. The *phosphorus* in SIL-FOS not only helps to lower the flow point, but it tends to act as a deoxidizer, reducing the amount of flux necessary with SIL-FOS. In fact, in some cases, copper-to-copper joints can be made without any flux. Laboratory tests with such joints have shown a tensile strength of 33,000 lbs. per sq. in. This means neater joints and less labor-time in cleaning and finishing.

PENETRATES QUICKLY,

making strong, sound joints on copper and other non-ferrous metals and alloys.

SOLD BY THE POUND

in rods and strips at remarkably low prices for a silver alloy.

Welding Permits Production According to Design. J. P. WATERS. *Industrial Record*, Vol. 2, Mar. 1931, pages 25–27, 46–48, 61.
Detailed discussion of welding practice in a large plant manufacturing gas-operated domestic refrigerators. MFB(11c)

Gas-Welding Locomotive and End-Play Liners. F. R. WILLIAMS. *Welding*, Vol. 1, Aug. 1930, page 673.
The Canadian National Railway successfully uses gas welding to hold the liners in place. The procedure is described in detail. Ha(11c)

Regulations for Structural Welding in Germany. OTTO BONDY. *Iron Age*, Vol. 127, Apr. 2, 1931, pages 1074–1079.
Discusses structural welding development in Germany in the past 5 yrs. and gives regulations governing the erection of welded structures. Some of the requirements are that the location of welded seams to be made in the field should be marked in the shop. Methods may include arc welding, resistance welding or gas welding. For static calculation, design and execution the same principles hold good as for riveted structures. All welds must be easy of access for testing purposes. VSP(11c)

Electric Welding of Mild Steel by the Metal Arc Process. V. G. PEARSON. *Foundry Trade Journal*, Vol. 43, Aug. 21, 1930, pages 127–128.
Extracted from *Edgar Allen News*. The two greatest evils of welding deposit are porosity and slag inclusions. It is important to avoid steep walls when undercutting will take place. The training of operators is of paramount importance. Homogeneity of welds is discussed. VSP(11c)

Wider Adoption of Structural Welding Depends on Comparative Costs. A. F. DAVIS (Lincoln Electric Co.). *Metal Progress*, Vol. 19, Feb. 1931, pages 59–62.
Abstract of a paper presented before the Western Metal Congress, San Francisco, Feb. 16, 1931, and published in full with discussion in the Transactions of the American Society for Steel Treating. The author gives several examples of the expansion of welding in the construction of office and factory buildings. Uniformity and reliability of welded joints in structures are discussed with illustrations. Elimination of noise in erection and possible economies are the basis for the use of welding. Failure as yet to obtain real economies of cost in field erection has led to the use of welding to supplement riveting in shop fabrication of trusses and such. WLC(11c)

The Weldability of Aluminum Alloys as Dependent on the Type of Alloy. (Die Schweissbarkeit der Aluminium-Legierungen in Abhängigkeit vom Legierungstypus.) E. SCHEUER. *Die Schmelzschweissung*, Vol. 9, Aug. 1930, pages 178–182; *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 134–138.
The 3 most commonly used types of cast aluminum alloys are Al-Cu alloy (American alloy), Al-Cu-Zn alloy (German alloy) and Al-Si alloy (Silumin). Each of these is readily weldable to a different degree. The better weldability of the eutectic Al-Si alloy, as compared with the other two, is due to crystal structure and the solidification process. The German and American alloys are, before melting, brittle over a more or less extended temperature range because of melting of the eutectic "cement substance" between the aluminum crystals. Mechanical testing of the 3 alloys near the melting point by impact-bending tests showed the following:

Material	Temperature from Which an Impact Energy of 1.5 Mkg. Is Obtained	Reduction Point at Melting	Impact Energy at 5° C. below Inception of Visible Melting
	° C.		Mkg.
Silumin	3		1.5
American alloy	24		0.09
German alloy	45		0.07

The higher the temperature to which the material can be heated without destroying the plasticity, the better the hammer welding can be made. German and American alloys cannot be hammer welded because of their low eutectic temperatures and the resultant low plasticity, but silumin is suitable for this process and the welded seams show approximately the same strength as the normal soft silumin sheets, i. e., about 14 kg./mm.^{2} for autogenous welding and 16 kg./mm.^{2} for hammer welding. Ha(11c)

Gas-Welding of Heavy Plate Construction. O. A. DAVIS. *Welding*, Vol. 1, Aug. 1930, pages 693–696.
Describes some high-pressure tanks and kilns of large dimensions formed of welded plates. Modern shop equipment and good welding operators are essential to success. Ha(11c)

Electrically Welded Crane in Upper Silesia. (Elektrisch geschweisster Laufkrahn in Oberschlesien.) DECKE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Feb. 21, 1931, page 233.
A 10 ton, 19.2 m. span crane, entirely welded, was tested with 20,000 kg. (double load) and showed 32 mm. deflection ($^1/_{600}$ of the span) which disappeared entirely after the load was taken off. The weight of the crane is 3 tons less than that of an equal riveted crane and the cost is 20% less. Ha(11c)

Structural Welding, Its Present Status and Future Chances, J. E. FERGUSON (The Austin Co.). *Metal Progress*, Vol. 19, May 1931, pages 51–55, 108.
The author states that the reliability of properly welded joints has been proven the equal or superior of riveted joints in steel structures. Field erection, however, requires careful preparation and study of costs before undertaking. Various buildings and structures recently erected by welding are named. Advantages of welding are real and their value is becoming impressed on the minds of architects, engineers and construction companies. The factors essential to the future development of welded structures are discussed. WLC(11c)

The Strength of Arc Welded Joints. F. R. FREEMAN. *Engineering*, Vol. 131, Feb. 6, 1931, page 192.
Abstract of paper read before the Institution of Civil Engineers, Jan. 27, 1931. LFM(11c)

A Remarkable Welding of a Large Tank. (Eine bemerkenswerte Grossbehälterschweissung.) O. WUNDRAM. *Die Schmelzschweissung*, Vol. 9, May 1930, pages 122–125.
A large heat storage tank (10 m. in diameter, 35 m. high, of single sheet of 1.80 × 5.30 m. and from 20.5 mm. thickness at the bottom to 6 mm. at the top) for the central heating plant of the Hamburg Electricity Works was entirely lap welded. The erection was completed in 5 months (winter). The welding was done by direct circuit with 4 mm. electrodes and 165 amp., 40 volts. Ha(11c)

Influence of Welding Current Conditions with the Electric Arc Welding of Soft Steel. (Einfluss der Schweissstrombedingungen bei der elektrischen Lichtbogenschweissung von weichem Flussstahl.) N. LEFRING. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Feb. 21, 1931, pages 223–224.
The interrelation of melting conditions at electric arc welding and the influence on melting velocity of kind of current, polarity and kind of electrode are determined by experiments. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 41. Ha(11c)

Electrically Welded Pulleys. (Elektrisch geschweisste Riemenscheiben.) WILLIBALD SENFT. *Elektrotechnik und Maschinenbau*, Vol. 48, Sept. 21, 1930, pages 886–888.
Describes method of welding and compares costs of cast and welded pulleys. MS(11c)

Stresses in Materials Cut with Oxygen. (Materialspannungen bei Sauerstoffschnitten.) L. v. ROESSLER. *Autogene Metallbearbeitung*, Vol. 24, Mar. 1, 1931, pages 65–75.
It is shown that cutting with oxygen causes stresses in the material which can sometimes assume injurious values. A method is described by which these strains have been measured so that the magnitude and distance within which the stresses occur can be determined. If a material has been cut in the cold state, such stresses can be made to disappear by annealing. If cutting with oxygen is done on pre-heated material, no interior stresses remain. Ha(11c)

Lengthening Rails by Butt-Welding. L. C. RYAN. *Welding*, Vol. 2, Jan. 1931, pages 22–24
In railroad operation, rail joints are the primary cause of many service troubles; therefore, the elimination of as many joints as possible is now an accepted practice. While lengthening of rails up to 66 ft. has helped considerably, it is now urged to weld together stretches as long as 1000 ft. as it has been proven that expansion and contraction from temperature changes take place only in about 40 ft. at the end of any length of solid rail. The advantages from this method are pointed out especially in safeguarding and reducing costs of operation. See also *Metals & Alloys*, Vol. 2, Feb. 1931, page 39. Ha(11c)

Electrically Welded Tool Holders and Chucks. (Elektrisch geschweisste Messerhalter und Spannbacken.) SENFT. *Elektrotechnische Zeitschrift*, Vol. 52, Feb. 26, 1931, pages 297–298.
A few examples of multiple tool holders which could be made by welding at about 35% of the cost of cast steel pieces. Weight of the pieces was about 30 lbs. Ha(11c)

Arc-Welding for Structural Buildings, Tank Construction and Machinery. (Lichtbogenschweissung im Hoch-, Behälter- und Maschinenbau.) E. R. RUCK. *AEG-Mitteilungen*, May 1931, pages 323–327.
The advantages of arc-welding are shown on a few typical examples. Ha(11c)

Tenth International Acetylene Congress. E. DACRE LACY. *Welding*, Vol. 1, Nov. 1930, pages 915–918.
The congress was held in Zurich, Switzerland. 67 papers were read on subjects pertaining to the theory and practice of welding and metal cutting, and upon the aspect of oxygen and acetylene. The program of the congress and a brief résumé of some papers are included. Ha(11c)

Gas Welding Applied to Metal Airplanes. PAUL MCCOY. *Welding*, Vol. 1, Nov. 1930, pages 901–902.
Brief description of materials and methods used. Many of the parts are fabricated by welding including aluminum oil and gasoline tanks. Ha(11c)

Welding Inspection and Testing. R. KRAUS. *Welding*, Vol. 1, Aug. 1930, pages 668–673; Sept. 1930, pages 757–761.
The checking of the welders' ability and observation of the work in process are the outstanding ways of making inspection effective. By familiarity with the characteristics of good and bad welds, which are included in the paper, the inspector is assisted in judging the finished work while he has been observing each welder in turn in the group assigned to him. A variety of non-destructive tests for welded tanks are described. The soap bubble arc test in combination with a hot oil test is practiced for tanks made of thin materials, while high pressure oil tests are applied to tanks fabricated of plates. Numerous examples of laying out and carrying out the work and of the application of tests are illustrated. Ha(11c)

The Dynamic Characteristic of Welding Generators. (Die dynamische Charakteristic von Schweissstromerzeugern.) H. LANGKAU. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Feb. 28, 1931, pages 263–266.
The dynamic characteristic of the welding generator with self-excitation is that curve showing the behavior of terminal voltage at fluctuations of current (load) as they occur in practice. It is noted that the present machines are not yet perfect, in so far as the unfavorable dynamic characteristic and the low efficiency are due to the fact that the EMF does not respond properly. The machine should be much more sensitive at diminishing current and not, as at present, for increasing current. A desirable characteristic is derived. Ha(11c)

Welding with Atomic Hydrogen Process. SAM. MARTIN, JR. *Welding*, Vol. 1, Nov. 1930, pages 907–909.
A discussion of the fundamental principles of the process and its equipment, manner of functioning and the consumption of tungsten electrodes around which the molecular hydrogen is dissociated into atomic hydrogen. Curves illustrate welding current for different thicknesses of plates and the respective welding speeds. Ha(11c)

Outline of Welding and Allied Processes. F. L. LLEWELLYN (U. S. Steel Corp.). *Metal Progress*, Vol. 18, Dec. 1930, pages 95–104; Vol. 19, Jan. 1931, pages 51–56, 104–107.
The author defines welding and discusses surface conditions and source of heat. Special attention is given to the characteristics and interrelation of newer processes. Description of specific methods, forge welding, resistance, electropercussion, arc welding, gas cutting and thermit welding is given with discussion of the history and applications of these methods. Data on the heat treatment of welds and welded parts and their physical properties are given. Questions of cost and patent situations are discussed. A chart shows a classification of various processes and their applications. Study and development of the technique for every welding application are essential to good results and promise further growth of this method of fabrication. WLC(11c)

The Welding of Structures. H. MARTIN. *The Welder*, Vol. 2, Mar. 1931, pages 12–14.
A brief discussion of how a weld should be made. As working loads for lap welds the author gives the following figures with a safety factor of 4:

Size of Fillet	Tons/linear in. of weld (in longitudinal shear) Bare Wire	Medex	Cresta
$^1/_2$ in.	1.5	1.75	2.0
$^3/_8$ in.	1.33	1.5	1.8
$^5/_{16}$ in.	1.12	1.25	1.35
$^1/_4$ in.	0.75	1.0	1.2

The speed of welding is given as roughly proportionate to the electrical energy consumed in the arc, i. e., equal to volts × amperes. Where the work is exposed to weather or corrosive conditions, it should be sealed by welding from the atmosphere around every joint irrespective of the amount of weld metal necessary for carrying the load. Ha(11c)

The Design of Welded Steel Structures. Part IV. H. A. MCCREADIE. *The Welder*, Vol. 2, Feb. 1931, pages 3–6.
This installment deals mainly with the making of reinforcements to plates, girders, etc., and how they must be dimensioned. Ha(11c)

New Science of Welding Makes Great Changes in Industry. C. J. MCGREGOR. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 81–82.
A general discussion of welding and its applications. Ha(11c)

Welding and the Building Codes. F. P. MCKIBBEN. *Welding*, Vol. 1, Sept. 1930, pages 739–744.
A review of the building regulations in different states and a list of cities which have included welding in their codes. The qualifications for welders are also discussed. Ha(11c)

The Welding of Aluminium and Its Alloys. (Das Schweissen des Aluminiums und seiner Legierungen.) F. GOLDMANN. *Aluminium, Hauszeitschrift V. A. W. Ertfwerk*, Vol. 3, Apr.-June, 1931, pages 142–146.

A general discussion of welding methods for aluminum products (not cast aluminum), their particular qualities and advantages for certain purposes. The great possibilities of electric resistance welding is especially treated and a few machines for spot welding, butt welding and seam welding are illustrated. It is particularly pointed out that, due to the small mass of the heated metal and the quick cooling effect of the electrodes, the structure of the welded joint is not changed back to the cast structure and the solid solution is not disintegrated. The resistance-welding method is very good for quantity production. Hammer welding is expensive and gives a high grade of joint, but it requires special care and, therefore, is used only for valuable pieces. Ha(11c)

Physical Aspects of Structural Joints. JAMES R. GRIFFITH. *Welding*, Vol. 1, Aug, 1930, pages 678–680.

Welded connections should be designed to utilize the particular advantages of welding in order to eliminate some of the undesirable factors commonly found in a riveted joint. The author's conclusions are illustrated. Ha(11c)

Test Results of Welded Misco Joints. W. A. HAKIN. *Welding*, Vol. 1, Nov. 1930, pages 910–912.

Misco electrodes have the following composition: Ni 35%, Cr 15%, C 0.50%, Si 1.25%, Mn 0.70%, S 0.045%, P 0.045%, Fe 47.46%. This steel is a heat resisting alloy and is used for structural and mechanical parts operating at temperatures up to 2000° F. The method of calculation of the stresses in the fillets is given and some test results are reproduced. Ha(11c)

Changes of Material of Structural Steels Machined with the Cutting Flame. (Werkstoffveränderungen der mit Schneidbrennern bearbeiteten Baustähle.) A. HILPERT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 23, 1931, pages 649–652.

German rules and regulations often require that autogenously cut surfaces be machined (planed, milled, filed, ground, etc.), assuming that the cut surface has been weakened. Tests have proved that in the great majority of cases, properly made autogenous cuts do not require subsequent machining. The tests employed include tensile tests, folding tests, dynamic tests and examination of the cut surface. It would seem, therefore, that these rigorous rules might safely be modified with benefit to the manufacturer and the customer through savings in material and labor costs. Ha(11c)

Welded Steel Drums for Scout Cruisers. J. C. HODGE (Babcock & Wilcox Co.). *Metal Progress*, Vol. 19, Mar. 1931, pages 40–45.

A paper presented before the Western Metal Congress, San Francisco, Feb. 16, 1931, to be published in the Transactions with discussion. Determination of physical and chemical properties of representative welds, nondestructive examination by X-rays, and hydrostatic testing of finished vessels are the basis of specifications to insure good welded vessels. WLC(11c)

Repair Welding of Gears. (Reparaturschweissungen an Zahnrädern.) H. HOLLER. *Autogene Metallbearbeitung*, Vol. 23, June 1, 1930, page 173.

A few illustrations of successful welding of cast iron wheels. Ha(11c)

The Weldability of Aluminium. (Die Schweissbarkeit des Aluminiums.) H. HOLLER. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June, 1930, pages 123–133.

Discussion of welding to produce a joining between 2 materials which is technologically equivalent to the materials joined. This matter is discussed with regard to the development of the different methods of welding aluminum and the manner and limits of their application. Welding methods are supplemented by homogenizing. Welding can be replaced, to a certain extent, by soldering or riveting. With soldering, additional material of different elements is used; undesirable heating of the joint and neighboring zones (by cold riveting which finds its principal application for the refinable aluminum alloys whose joints must not be exposed to welding or soldering heat). Their welding methods and their particular qualities are described. Numerous illustrations and microphotographs illustrate welds which are satisfactory and those which are defective. Ha(11c)

Welding instead of Casting. (Schweissen an Stelle von Giessen.) H. HOLLER. *Autogene Metallbearbeitung*, Vol. 23, Oct. 1, 1930, pages 299–302.

Points out the many advantages which can be gained by welding together complicated forms from single parts instead of casting or riveting them. This is especially true if only one or a few pieces are required, since a costly pattern is saved. Ha(11c)

Research Covering Alternating Current Arc Welding. GROVER A. HUGHES & R. C. MCBRIDE. *Iron & Steel Engineer*, Vol. 8, June 1931, pages 241–246.

Results of the research are shown for welded steel, aluminum, Ascoloy, Monel metal, copper. Alternating current arc welding was found satisfactory as to tensile strength, ductility, rate of depositing metal, and current consumption. Efficiency of welders is high, and voltage and current curves are ideal. Satisfactory welds can be made with bare electrodes and with non-ferrous metals. WHB(11c)

The Action of Purifying Agents for Acetylene and the Influence of Contents of Phosphite and Sulphide of Hydrogen in Acetylene on the Welded Seam. (Ueber die Wirksamkeit von Reinigungsmassen für Azetylen und den Einfluss des Phosphor- und Schwefel-wasserstoffgehalts im Azetylen auf die Schweissnaht.) P. K. HOLZHAEUSER. *Autogene Metallbearbeitung*, Vol. 23, Sept. 1, 1930, pages 266–275; Sept. 15, 1930, pages 286–296.

Of all purifying agents, the most effective were found to be materials of calcium chloride; and after these, materials of bi-chromate; other materials for the purpose were less effective than either of these. Since dry gas cannot be purified, it is important that the gas not be dried before purification. Contents of 0.02 vol. % of hydrogen phosphide or 0.05 hydrogen sulphide are not harmful to the quality of the welded seam. Very careful tests and the arrangements necessary to making them are described and 28 references are cited. Ha(11c)

Stresses in Large Fillet Welds. CHAS. H. JENNINGS. *Product Engineering*, Vol. 2, Mar. 1931, pages 116–118.

A discussion of the magnitude and calculation of stresses in fillet welds leads to the conclusions that the larger the fillet, the greater is the probability of large residual stresses. The larger the fillet weld, the lower its yield point and ultimate unit strength in transverse bending. The ultimate strengths obtained were:

$^3/_4$ in. weld	43,500 lb./in.^{2}
1 in. weld	38,300 lb./in.^{2}
$1^3/_8$ in. weld	33,600 lb./in.^{2}

Welds located in several places close together should be welded simultaneously rather than successively in order to prevent excessive stresses in the first weld. Ha(11c)

How to Arc Weld Cast Iron Successfully. THOS. D. KETCHBAW. *Welding*, Vol. 1, Nov. 1930, pages 919–922.

Preheating is a most essential factor in successful welding of cast iron. Details of technique and cost figures for several interesting jobs are cited. Ha(11c)

Investigations of the Left Welding, Old and New Right Welding in Different Positions of the Work Piece. (Untersuchung über die Links, alte und neue Rechtsschweissung bei verschiedenen Stellungen des Werkstücks.) H. SCHAEFER. *Die Schmelzschweissung*, Vol. 9, Oct. 1930, pages 225–228.

For horizontal and vertical positions, the new right welding gave the best results with regard to consumption of gas, wire and time. For a less experienced welder, the old right welding is better. With some practice, this method can give almost the same strength as the new method. For overhead positions of the work piece, no noticeable difference between the three methods could be found, either for output of the welder or for consumption of gas and wire. Ha(11c)

Influence of Acetylene Pressures on the Quality of the Welded Seam. (Einfluss der Azetylendrücke auf die Güte der Schweissnaht.) K. GABLER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Jan. 17, 1931, pages 77–81.

An investigation was made to determine, for small shops or work in the field, whether low, medium or high pressure acetylene is more advantageous when the quality of the weld is the determing factor to be considered. Tests were made under practical conditions on sheets of 1000 mm. length, 100 mm. width and 10 mm. thickness. Analyses, gas consumption, mechanical and metallographical examination are reproduced in full. It is found that, under conditions as prevailing in small operations, dissolved acetylene is preferable to all other gases. Ha(11c)

Repairs of Gray-Cast Machine Parts by Gas Fusion-Welding with the Application of Special Bronze. (Reparaturarbeiten an Grauguss-Maschinenteilen mit Hilfe des Gasschmelzverfahrens unter Verwendung von Specialbronze.) A. GLATZEL. *Autogene Metallbearbeitung*, Vol. 23, Oct. 15, 1930, pages 325–328; Nov. 1, 1930, pages 334–336.

Several examples of successful repairs on gears, bearings, dynamo frames, etc. Ha(11c)

The Question of Time or Piece Work in Welding. (Zur Frage des Akkordschweissens.) H. MELHARDT. *Autogene Metallbearbeitung*, Vol. 24, May 1, 1931, pages 134–137.

Factors influencing the manner of paying for welding (whether by piece or time) are thoroughly discussed. That welders should do absolutely nothing but welding work, is emphasized. The welder must receive exact instruction as to what to do and how to do it. His work should be confined to welding—to weld as quickly, as well and as economically as possible. The shop foreman must care for arrangement of seam, preparation of sheets and sequence of welds. Directions as to gas pressure, size of flame, manipulating of welding rods, etc., should be given. Under these conditions, the good welder is easily recognized and a fair price for piece work can be made. Ha(11c)

The Metallurgy of Welded-on Overlays. MILES C. SMITH. *Welding*, Vol. 1, Aug. 1930, pages 681–683.

Hard facing is very often necessary; the characteristic properties and methods are discussed. In order to avoid stresses in the welded-on overlay, the preheating of the mother material is necessary, usually to a dull red heat. Microphotographs illustrate the proper amalgamation of the overlay and the fused material. Wear-resistant materials which may be used for such overlays are W, Zr, Cr, Mn and Si. Some of the characteristics of these materials are discussed. Ha(11c)

Fixtures and Dies for Flash Welding. W. E. SMITH. *Welding*, Vol. 1, Aug. 1930, pages 687–688.

Discusses some reasons for defective welds due to misalignment of parts, reduction of clamping pressure, wear of dies and considers means of avoiding them. Ha(11c)

Unfired Pressure Vessels. W. SPRARAGEN (American Bureau of Welding). *Industrial Gas*, Vol. 12, Mar. 1931, pages 10–16.

Application of fusion welding to fabrication of pressure vessels. This paper based on series of results of tests in 1923 under head of American Bureau of Welding with aid of U. S. Bureau of Standards, the Unfired Pressure Vessel Code of A. S. M. E. and experiences of others. Fundamental factors considered: (1) selection of material of good welding quality and use of good welding wire; (2) correct design of vessel and welded joints; (3) use of qualified welders; (4) proper preparation of material for welding; (5) employment of proper technique; (6) testing of finished vessel. DTR(11c)

Influence of Magnetism on the Welding Arc. R. M. STEPHENS. *Welding*, Vol. 2, June 1931, pages 369–371.

The magnetic fields set up between electrode and work piece and their effect in blowing out the arc or making it unsteady under certain conditions are explained. Several schemes have been developed to overcome these magnetic effects and to insure a resulting magnetic field of proper direction and magnitude. A few of these methods are illustrated. Ha(11c)

Responsibilities of the Welding Engineer. ROBERT E. STORM. *Welding*, Vol. 1, Oct. 1930, page 849.

Advocates the services of a competent specialist to advise in welding problems. Ha(11c)

Stresses in the Sheet and Welded Seams in the Construction of Pipe Lines and Tanks. (Blech-und Schweissnahtspannungen im Rohrleitungs- und Behälterbau.) H. SCHAEFER. *Die Schmelzschweissung*, Vol. 9, July 1930, pages 159–161.

Means are discussed to eliminate or at least diminish the heat stresses occurring in autogenous welding by proper selection and arrangement of the seam. Good heat conduction is always of importance so that no overheating at single spots can take place. Certain directions can be given from experience for the welding of cover plates, flanges on pipes and high pressure tanks. Ha(11c)

The Combined Autogenous-Electric Welding Process, "Arcogen." (Das kombinierte autogen-elektrische Schweissverfahren "Arcogen.") H. MUENTER & E. WISS. *Autogene Metallbearbeitung*, Vol. 23, Nov. 15, 1930, pages 349–356; Dec. 1, 1930, pages 365–373.

This new method combines the advantages of autogenous welding, which gives welds of very good elongation, with that of arc welding, which produces but very small heat stresses and is, therefore, especially suitable for welding complicated pieces. The gas-technical and the electrical phenomena of the combined process are discussed and the manipulation of electrode and flame is described in detail. The tests on welded pieces by tensile, bending and metallographic methods proved that this method can be applied, not only for steels and iron but also for copper and aluminum. Materials which are sensitive to overheating and which burn readily are adaptable to this method. Illustrations are given of built-up welding, butt welding, overlap welding, etc. The velocity of welding by this method is about 50% higher than that for gas welding. A comparison of economy shows about 30% in favor of the "Arcogen" method. The discussion of this paper supplements it with more practical information. Ha(11c)

The Welded Field Tube Boiler. (Der Geschweisste Fieldrohr-Dampfkessel.) WALTER GOLDSTEIN. *Die Schmelzschweissung*, Vol. 10, Apr. 1931, pages 92–93.

An improved construction of the suspended pipes of the Field tube boiler is described, some installations (not in Germany) are described and the welding methods applied for this particular purpose are illustrated. Ha(11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Clean Steels from the Acid Open-Hearth. C. H. Herty, Jr. (U. S. Bureau of Mines) & J. E. Jacobs (Heppenstall Co.). *Metal Progress*, Vol. 19, Feb. 1931, pages 93–99; *Blast Furnace & Steel Plant*, Vol. 19, Apr. 1931, pages 553–556; May 1931, pages 683–686.

An abstract of a paper, "Formation and Elimination of Non-Metallic Inclusions in the Acid Open-Hearth Process," read at the Western Metal Congress, San Francisco, Feb. 16, 1931. Study carried out by agreement between U. S. Bureau of Mines and Heppenstall Co. on the acid open-hearth process with 2 grades of Ni-Cr-Mo-Va steel. The factors studied were: (1) elimination of non-metallic matter in the charge and from the furnace lining, (2) oxidation of metal during the heat, (3) deoxidation with alloys, (4) elimination of silicates in the ladle, (5) segregation of non-metallics in the ingot and (6) slag reactions. The experimental work was done in 20 ton furnaces at Heppenstall with average heats of 57,000 lb. To date the first 4 items have been studied in detail. Acid practice as to charge and method of working is briefly outlined. Elimination of silicates formed by oxidation of the melt down is effected by an ore boil with an addition of spiegel to aid in fluxing the silica. Spiegel addition eliminates much greater portion of silicates than the ore boil alone. After this clean-up the bath begins to "dirty up" apparently from the furnace bottom. Grade of sand and method of making the bottom are probably connected with this condition. Manganese-silicon alloy followed by a small manganese addition eliminates inclusions from this source. The manganese-silicon alloy gives a much cleaner steel than ferrosilicon and ferromanganese. Curves show the silicates present during the working of the heat and the FeO present, determined by the aluminum method described in reference referred to. A discussion of slag conditions and composition precedes the report on use of deoxidizers. Two curves show the amount of silicates present during the addition of ferrosilicon and ferromanganese and for the manganese-silicon alloy. A curve shows the eliminations of silicates during the pouring where holding the steel as long as possible in the ladle is of direct benefit in eliminating non-metallic matter and puts the steel in better condition of temperature to cast. WLC(12a)

Study of Nonferrous Crucible Melting. Harold E. White. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Sept. 1930, pages 441–459.

A discussion on the use of nonferrous crucible melting furnace from the metallurgical, mechanical and economical point of view. CHL(12a)

Uses for the Platinum Metals. Bernard Holman. *Canadian Mining Journal*, Vol. 52, May 29, 1931, pages 556–557.

A brief discussion of the precious metals refinery of the Mond Nickel Co. at Acton. Platinum of 99.93% purity and palladium of 99.94% purity are produced. "The development of a small scale laboratory method for the recovery of palladium from jewelers' lemel and 'white gold' scrap would help extend the use of palladium." WHB(12a)

High Frequency Induction Furnace for Making Tool Steel. J. A. Succop (Heppenstall Co.). *Metal Progress*, Vol. 18, Dec. 1930, pages 40–44.

Advantages of the induction furnace for intermittent operation and for high alloy charges are described. The problem of refractories is discussed with reference to patching magnesia and the use of zirconia. Ease of temperature control and the vigorous stirring action in the bath are in favor of this furnace. The reality of claims of superiority in induction furnace steel have not been definitely proven. WLC(12a)

Constant Care Needed in Alloy Steel Manufacture. A. D. Shankland (Bethlehem Steel Corp.). *Metal Progress*, Vol. 19, Apr. 1931, pages 53–57.

The author describes the selection of raw materials, furnace and pit practice and method of control and inspection of high grade alloy steels. WLC(12a)

Fire Refining and Casting of Electrolytic Copper. L. C. Fopeano. *Engineering & Mining Journal*, Vol. 131, June 8, 1931, pages 515–517.

An attempt to suggest instruments useful in an investigation, and to outline some data on the practical operation of refining furnaces. Improper fuel control and temperature are considered the underlying causes of most refinery troubles. The various periods of the process are discussed, emphasis being given to factors effecting satisfactory control. The periods discussed include: charging, melting, skimming and blowing, poling and casting. A prolonged study of the effect of temperature on casting defects and casting efficiency showed that cracks, side splashing, porous spots, pits and imbedded mold wash increased as the cutting temperature increased. WHB(12a)

Casting & Solidification (12b)

Permanent Molds and the Influence of Cooling Rate on Gray Iron. (Ueber Dauerformen und den Einfluss der Abkühlungsgeschwindigkeit bei Grauguss.) E. Köttgen, Doktor-Ing. dissertation, Tech. Hochschule, Berlin, 1930, 14 pages, 21 figures, 22 references. Published by Giesserei Verlag, Düsseldorf.

The effects, upon a cast iron of 3.5% C, 2.5% Si, 0.4% Mn, 0.4% P, 0.1% S poured into cast iron molds, of casting size, mold thickness, mold temperature, casting temperature at constant melting temperature and variable melting temperature at constant casting temperature are given in curves, showing the resulting Brinell hardness. Electrically heated molds were used. By taking castings from the mold before they pass through the critical and then cooling at different rates, the hardness was varied from 320 to 180 Brinell. Castings frozen at such a rate that they were white on the outside were graphitized by heating 20 minutes at 900° C. A strength of 57,000 lbs./in.^{2} can be thus obtained. When the freezing rate, measured from 80° C. above the solidification point, down to the end of solidification, was over 500°/min., the structure was ledeburitic; over 300°/min., it showed eutectic graphite, over 200°/min., fine graphite, and below 200°/min., coarse graphite. By vacuum melting and by deoxidation with Al, Köttgen concludes that the effect of superheating the melt upon size of graphite flakes is connected with gas content. If the iron is oxygen and gas free (as when melted with a neutral powdered coal flame) it will have exceptional physical properties. Permanent mold castings should be cast in molds $1^1/_2$ to 2 times as thick as the part to be cast, and should be reheated to 300–400° C. The best way to control the cooling rate is to coat the mold face with an egg-shell thick refractory coating. This will last for 200–300 castings, if smoked with an acetylene flame between each cast. HWG(12b)

Casting Aluminum Pistons in Permanent Molds. G. D. Welty (Aluminum Co. of America). *Metal Progress*, Vol. 19, June 1931, pages 90–93.

Casting and heat treatment technique for aluminum alloy pistons for Diesel engines is described. WLC(12b)

Die Castings Reduce Machining. C. R. Maxon. *Machine Design*, Vol. 3, Mar. 1931, pages 42–44.

Casting with air or with mechanical external pressure or with a combination of both is best suited for rapid production of strong, sound castings. The zinc die casting alloy known as "4-3-1" is one of the most satisfactory. It has a tensile strength of 46,000 to 48,000 lbs./in.^{2} The properties of this alloy are tabulated and a number of castings, some with inserts of other materials, are described. Ha(12b)

Design of Steel Castings. C. E. Sims. *Octagon*, Vol. 35, June 1931, page 6.

Points out the importance of the use of proper design, particularly for molding, in order to get a satisfactory, sound casting. Ha(12b)

Rolling (12c)

Seamless Steel Tubing Made in Large Sizes. G. P. McNiff. *Metal Progress*, Vol. 19, May 1931, pages 39–45.

A paper read before the Western Metal Congress, Feb. 1931, San Francisco, to be published completely with discussion in the Transactions. The author describes the Mannesmann and Stiefel piercing mills. The National Tube Company's development of a double piercing method for making large sizes of seamless tube is described and discussed with reference to savings in production. WLC(12c)

The Reasons for the Dependence of the Rolling Process upon the Diameter of the Rolls. (Die Ursachen der Abhängigkeit des Walzvorganges vom Walzendurchmesser.) L. Weiss. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 47–50.

Based on experimental experiences the author claims the superiority of roller bearings in comparison with friction bearings due to a larger loss in friction of the latter. The beginning of the deformation resistance K_f beyond the static flow pressure σ is discussed and a mathematical formula derived for the evaluation of K_f. The graphical determination of the sliding distance is shown and the pressure for the remaining length of deformation computed. An approximate distribution of pressure over the whole length of deformation is deducted therefrom and the possibility of computing the distance of the resulting rolling pressure from the rolling center is outlined. The author proves that in case of $\tan \alpha \geqq \mu$, the rolling process takes place in three steps and in an irregular manner; but if $\tan \alpha < \mu$ the process takes place in two steps consistently and with very large lead. The dependence of the rolling process upon the size of the rolls is considered and the impossibility of applying large passes in case of large diameters of the rolls is discussed. In conclusion the author deals with the experimental results of Pomp and Siebel recently published. EF(12c)

Concentrated Pressure and Some of Its Applications to the Rolling Process. A. Nadai. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1057–1092.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. Several cases of elastic distribution of stress produced by concentrated loads are treated. Attempt is made to apply the information obtained by analysis to cases of similar distributions of stress produced in rolling and thus determine more exactly what goes on in severely pressed parts of rolled sheets. WLC(12c)

Recent Development of Rolling Mills for Non-Ferrous Metals. (Die neuere Entwicklung der Walzwerke für Nichteisenmetalle.) L. Weiss. *Zeitschrift für Metallkunde*, Vol. 23, Mar. 1931, pages 73–86.

The paper presented before the Deutsche Gesellschaft für Metallkunde, Berlin 1930, reviews the development of rolling mill constructions for nonferrous metals and emphasizes the multiple rolling mill system with small diameters of the rolls. Stress is laid upon the utilization of roller bearings and the various systems of multiple rolling mills are described. The phenomena occurring in the slit are discussed and attention is focussed upon the large pressures in the housing. The control of the latter is urged in order to protect the expensive roller bearings. In conclusion the speaker discusses fractures encountered in hardened supporting rolls and multiple roll housings and denies the necessity of hardening the latter. EF(12c)

Merchant Mills. U. A. Peters. *Rolling Mill Journal*, Vol. 4, Aug. 1930, pages 407–408.

Discusses briefly requirements of a merchant mill, size of billet to be rolled, power requirements and speeds. MS(12c)

Electrical Developments in the Iron and Steel Industry for 1930. D. W. Dean (Westinghouse Electric & Mfg. Co.). *Rolling Mill Journal*, Vol. 4, Dec. 1930, pages 651–656.

Discusses extensive application of electrical equipment to rolling-mill drives, their auxiliaries and related steel-mill equipment. Total horsepower applied to main drive motors for year ending Dec. 1, 1930 was 151,540, as compared with 139,350 the preceding year. MS(12c)

Remarkable Tear-Formation upon the Rolling of Noble-Metal Wires. (Merkwürdige Rissbildung beim Walzen von Edelmetall-Drähten.) L. Nowak. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 52–53.

Includes discussion. Noble-metal alloy wires were observed frequently to split lengthwise on rolling. Hard gold alloys split lengthwise but the cleavage surface was not flat but serrated and bent like the face of a cog-wheel. This is explained by a jerky application of load during over-stressing owing to an insufficient separation of rolls. Similar tears can be produced in brittle substances by pressure. RFM + EF(12c)

Motor and Control Equipment for Cold Strip Mill Drives. F. Mohler. *Iron & Steel Engineer*, Vol. 8, June 1931, pages 272–287.

The author discusses driving and control equipment in the cold rolling mill under the headings, Cold Rolling, Motors and Control. Two methods of control are discussed, giving diagrams of the electrical circuits. WLC(12c)

Forging (12d)

Quality of Drop Forgings Require Close Control. Adam M. Steever (Great Lakes Forge Co.). *Metal Progress*, Vol. 18, Nov. 1930, pages 45–49.

Closer tolerances on forgings have resulted in the hammers being more precisely made and aligned and impose greater stresses upon them than formerly. Better selection of the materials of which the hammers are made has led to less standby requirement in the hammer shop. Study of the clearances in the press and the temperature effects shows the difficulties of producing a forging 8″ × 2″ overall to a tolerance of $^1/_{64}$″. Coin pressing or cold hammer restrike methods are the only ways of producing real precision forgings. Heating furnaces with automatic temperature control assist in making good forgings. High quality of forging stock is essential. Defects from the forging practice are discussed and their remedies suggested. Quality of dies and die design are discussed. Very close control by frequent etching of the product is necessary to insure against defective forgings. WLC(12d)

Extruding (12f)

The Extrusion Process for the Production of Brass Rods, Tubes & Sections. A. Wragg. *Royal Technical College Metallurgical Club Journal*, Glasgow, No. 7, 1929–30, pages 3–8.

Very general description of the process. HWG(12f)

Heating Control in Cable Insulating. A. M. Stock. *Wire & Wire Products*, Vol. 5, Nov. 1930, pages 420–421, 443–444.

Description of insulating cables by means of lead extrusion presses. Special reference to heat control. GN(12f)

DEFECTS (13)

Occurrence of Fish-Scale in High Speed Steel. G. R. Brophy, R. H. Harrington & A. W. Merrick (Research Laboratories, General Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 440–458.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion, 3 references to the literature and macro- and micrographs illustrate the structures. Fish-scale fracture in hardened high speed tool steel is due to abnormal grain growth in the austenite. An extended study by the authors shows it to be due to thermal or mechanical strain produced while in the austenitic range. 14% W steel whether with 1 or 2% V showed this strain from air normalizing at 1560° F. or above. The 18% W steel showed fish-scale after hardening if previously air cooled from 2190° F. or above. The previous manner of working the material appears to have no influence. Deformation within the austenitic range produces similar results. Fish-scale has a bad effect upon tool performance. Drastic methods of annealing, according to the size of the piece, can be used to eradicate the condition. In discussion Sam Tour, Vice-Pres., Lucius Pitkin Co., N. Y., cites the occurrence of fish-scale in 8–10% and 5% W hotwork and die steels and relates it to the maximum and finish forging temperatures. WLC(13)

A New Forging Defect, Its Cause and Cure. W. E. Jominy & A. M. Steever. *Metal Progress*, Vol. 19, Jan. 1931, pages 94–97.

Defect is a surface hard spot showing only on individual inspection or in machining. The cause was found to be due to local carburized spots as shown in the microstructure. Most frequent occurrence of these defects found in an oil fired furnace with automatic control where for a portion of the time the oil burned with a smoky flame. Experiments checked the source of the local carburization as from coke formed by incomplete combustion of the fuel oil. Elimination of this defect lies in prevention of the formation of coke or its getting in contact with the work. WLC(13)

Why Did That Spring Break? E. E. Thum (Editor). *Metal Progress*, Vol. 19, Mar. 1931, pages 56–63.

Design, heat treatment, defects in springs, analysis and properties of spring materials are discussed. WLC(13)

Welding and Annealing. (Schweissen und Ausglühen.) W. Teuscher. *Die Schmelzschweissung*, Vol. 9, Mar. 1930, pages 62–64.

Material which is exposed, not only to compression and tension but also to impact and breaking stresses, is often found, after welding, to be of little resistance; it breaks off just at the welded seam. This was especially true with brake shoes of railroad freight cars where, frequently, welded corners broke away at the very first use despite an apparently perfect weld. Crystallographic examination revealed that, in such cases, large crystallites with the typical "hardness cracks" which only occur at sudden cooling from a temperature above 900° C. were present in the weld. In all cases, the weld showed a different structural picture from that of the material. The breaking could be avoided by a proper heat treatment after welding. The treatment consisted in annealing to at least 900°, but not exceeding 1000° C., for about 1/2 hr. The structure of both material and weld were the same. Ha(13)

CHEMICAL ANALYSIS (14)

Note on the Determination of a Very Small Quantity of Cadmium in a Rich Zinc Ore. J. G. Fairchild. *Chemist-Analyst*, Vol. 20, May 1931, pages 5–6.

After removal of the other metals of the Cu and As groups the filtrate is made not more than .3 N acid with H_2SO_4 and must be practically free from alkali salts. The cold solution is saturated with H_2S and allowed to stand 1 hour. Considerable ZnS should precipitate with the CdS. After filtering, the precipitate is dissolved in cold HCl, evaporated to dryness, dissolved in .3 N H_2SO_4 and reprecipitated with H_2S. This is again dissolved and precipitated as before to free it from Zn. The CdS is dissolved in HCl and evaporated with a drop of H_2SO_4 and weighed as $CdSO_4$. The proper acid concentration during precipitation is important. CEM(14)

Diphenylamine as an Inside Indicator for the Determination of Iron. Carroll B. Core. *Chemist-Analyst*, Vol. 20, May 1931, page 14.

Diphenylamine in a bichromate titration gives a sharp endpoint which does not fade like permanganate. H_3PO_4 is added to overcome the color of the iron salts. The solution can be back titrated with $FeSO_4$. V, Sn, Hg and Al do not interfere. $K_2Cr_2O_7$ and indicator solutions can be made up in large quantities as they do not deteriorate. Fe can be reduced by any standard method. 20 cc. H_3PO_4-H_2SO_4 and 3 drops indicator are added and the solution titrated till the green color changes to intense violet blue. Diphenylamine can also be used in a permanganate titration with the same color change. The end point does not fade even in the presence of much HCl. CEM(14)

Contribution to the Analytical Chemistry of Beryllium II. (Beiträge zur analytischen Chemie des Berylliums II.) H. Fischer & Grete Leopoldi. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 1–14.

In the first part an exact gravimetric method is described to determine Be in crude beryl and other beryllium-carrying ores and minerals and its usefulness is proved by analyses. The second part describes an analysis for determining Be in special steels containing beryllium, especially in chrome-nickel steels. All results of the analyses are given in detail. Ha(14)

Determination of Beryllium in Aluminum. H. V. Churchill, R. W. Bridges & M. F. Lee (Aluminum Research Laboratories). *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 12, Oct. 15, 1930, pages 405–407.

14 references. After a careful study of the various methods, it was found that a combination of the Havens and the 8-hydroxyquinoline methods is most satisfactory. When the separation of Al from Be becomes tedious and difficult by the Havens method, the 8-hydroxyquinoline method is most efficient. This procedure enables the analyst to evaluate his Havens separation because ignition of Al oxyquinolate precipitate reveals the amount of Al which the Havens method failed to remove. The recommended procedure is given in detail. MEH(14)

Non-Ferrous Metals and Alloys. Report of A. S. T. M. Committee B-2. W. Campbell, Chairman. *Preprint* No. 18 for June 1931 Meeting, *American Society for Testing Materials*. 12 pages.

A modification in wording of the directions for electrolytic assay of copper is recommended, and tentative methods proposed for determination of Ag, Cu, Cd and Zn in silver solders, as well as for Pb, Sn, Fe and Ni as impurities. HWG(14)

The Direct Determination of Sodium in the Presence of Aluminum and Chromium. Earle R. Caley & Darrell V. Sickman. *Journal American Chemical Society*, Vol. 52, Nov. 1930, pages 4247–4251.

It is shown that the direct magnesium uranyl acetate method for sodium is applicable in the presence of Al and Cr. The undesirability of having a high concentration of ammonium salts when making direct sodium determinations in sulphate solution is pointed out. MEH(14)

Rapid Estimation of Alloying Metals. Correspondence from C. H. Desch, Sheffield, England. *Metal Progress*, Vol. 18, Dec. 1930, pages 88–89.

The writer discusses the use of the spectroscope for analytical purposes in the study of alloys. WLC(14)

A Study of the Quantitative Precipitation of Calcium Oxalate in the Presence of the Arsenate Ion. J. T. Dobbins & W. M. Mebane. *Journal American Chemical Society*, Vol. 52, Nov. 1930, pages 4285–4288.

Calcium may be precipitated quantitatively in the presence of the arsenate ion. The solution may be made alkaline either before or after the addition of ammonium oxalate, and a small excess of ammonium hydroxide added. The best temperature for precipitation is 90–100°. MEH(14)

Spectroscopy as an Aid in Metallurgical Analyses. S. Judd Lewis. *Metallurgist*, Feb. 1931, pages 28–30.

A comparison of the analyses of iron, copper and carbon by the usual chemical analytical methods and spectroscopically showed a large number of elements undetected by chemical methods. The value of spectrographic control consists in (1) the discovery of unsuspected elements, (2) the detection and estimation of various impurities not usually comprehended in chemical analysis, (3) the examination of quantitative precipitates for their purity and (4) the correction of the gravimetric figures for the proportion of impurities carried by the precipitates. By these means much more precise assays can be obtained. VVK(14)

Cesium Sulfate as a Confirmatory Reagent in the Detection of Aluminum. Herman Yagoda & H. M. Partridge. *Journal American Chemical Society*, Vol. 52, Sept. 1930, 3579–3580.

The aluminum hydroxide, separated in the usual manner from the other III Group metals, is dissolved in 1–5 cc. of hot 3 M sulphuric acid. The resulting aluminum sulphate solution is cooled and 0.5–1 cc. of approximately 0.25 M cesium sulphate is added. On scratching the glass walls of the tube with a stirring rod, the dense white cesium alum separates and rapidly settles. MEH(14)

Titration of Lead Salts. R. C. Wiley, P. M. Ambrose & A. D. Bowers. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, pages 415–416.

The lead solution to be titrated should contain no other metals forming insoluble molybdates. It should be neutralized with ammonium hydroxide and any precipitated lead hydroxide dissolved by boiling with ammonium nitrate. The solution must be boiled until neutral and titrated with standard molybdate while hot. The end point is reached when a drop transferred to a spot plate containing the pyrogallol-chloroform indicator is colored brown. The results by this volumetric method check very closely with gravimetric results but the time required is much less by the volumetric method. MEH(14)

The Analysis of Silver-Plating Solutions. R. M. Wick. *Monthly Review American Electroplaters' Society*, Vol. 17, Dec. 1930, pages 14–19.

Methods for the determination of free cyanides, silver, carbonate, chloride and ferrocyanide are described. Ha(14)

Separation and Identification of the Alakli and Alkaline Earth Metals Using Isoamyl Alcohol. Herman Yagoda. *Journal American Chemical Society*, Vol. 52, Aug. 1930, pages 3068–3076.

A method for separating and identifying a mixture containing sodium, potassium, barium, magnesium, strontium and calcium is proposed. The essential features are: the conversion of the chlorides or nitrates to bromides with 8 *N* hydrobromic acid; separation of Na, K and Ba bromides from Mg, Sr and Ca bromides using isoamyl alcohol; separation of Na and Ba bromides from KBr using ethyl alcohol; precipitation of Na and Ba chlorides with 12 *N* HCl from the ethyl alcohol solution; separation of Mg from Ca and Sr by ignition of the nitrates; separation of Sr from Ca by dissolving Ca nitrate in 16 *N* HNO_3. MEH(14)

Determination of Cadmium Lead and Iron in High-Grade Zinc. B. H. Strom. *Engineering & Mining Journal*, Vol. 131, May 25, 1931, pages 465–466.

The methods employed in the laboratory of the Anaconda Copper Mining Co. are capable of determining such impurities as Cd, Pb and Fe in quantities of 0.001 per cent Pb and Cd are usually determined on the same sample. 100 g. of shot or drillings, in a two-liter beaker are moistened with 100 cc. of water and dissolved by 350–400 cc. of nitric acid. The cooled solution is treated with ammonia, with constant stirring till zinc hydroxide is dissolved, and 200 cc. excess added. Yellow ammonium sulphide (1:10) is added cautiously to precipitate Cd, Pb and a little Zn. Pb is determined as sulphate and Cd separated from the small amounts of Zn by precipitation with hydrogen sulphide in the filtrate from the Pb in hot solution. For Pb only: to a 100 g. sample is added 1 g. ferric sulphate and nitric acid, and the Fe precipitated with ammonia. This Fe precipitate is redissolved with hydrochloric acid (1:1) and fumed with 15 cc. sulphuric acid (1:1) and weighed, or titrated. Pb may be determined electrolytically in Zn, Cu or Cd by taking 86 g. of sample, dissolving in 320 cc. nitric acid and 100 cc. water, adding 2 g. calcium carbonate, diluting to 800 cc. with hot water and making strongly alkaline. Bring to boiling and precipitate with ammonium carbonate. Filter by decantation, washing the precipitate into a 250-cc. beaker, and dissolve the remainder on the paper with 3 cc. nitric acid, diluted with 20 cc. water. A few drops of silver nitrate solution and 1 cc. of strong copper nitrate solution are added, 200 cc. water added and the solution electrolyzed with .5–1.0 amp. with platinum electrodes. Fe is determined colorimetrically. WHB(14)

Determination of Antimony in Lead-Antimony Alloys of Low Antimony Content. Leon I. Shaw, Charles F. Whittemore & Thor H. Westby. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, pages 402–403.

Five references. Presented before Division of Physical and Inorganic Chemistry at the Atlanta, Ga., Meeting of the American Chemical Society, April 1930. Data are given by way of comparison of the three permanganate and two bromate methods, for the determination of Sb in two Pb-Sb alloys containing about 1% Sb. The method described here is a modification of the permanganate method, and eliminates the use of copper sulphate and uses concentrated sulphuric and fused bisulphate at 320° C. for dissolving sample. Heating is continued for 20–30 minutes, solution is cooled, diluted, HCl added, again heated to boiling for 15 seconds, cooled, diluted and titrated at 10–12° with permanganate. The method is claimed to be rapid and accurate for routine procedures. MEH(14)

Rapid Estimation of Carbon in Refining Stage. Correspondence from Einar Oehman, Stockholm, Sweden. *Metal Progress*, Vol. 19, Apr. 1931, pages 90–91.

The writer describes the "carbometer" invented 18 years ago and tried successfully for the rapid determination of carbon on the open hearth floor, by a magnetic method. On 271 heats aiming for a range of .60–.65% carbon with the aid of this instrument 93% of the heats came within the range, 5.5% .01% carbon high or low, and 1.5% of the heats .02% carbon high or low. WLC(14)

Rapid Method for Determining Calcium in Lead Alloys of Low Calcium Content. Leon I. Shaw, Charles F. Whittemore & Thor H. Westby., *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, pages 401–402.

Presented before the Division of Physical and Inorganic Chemistry at the Atlanta, Ga., meeting of the American Chemical Society, April 1930. By this method it is possible to complete a single determination in 25 minutes by uninterrupted attention of the analyst. Duplicates can be run in 45 minutes. Data are given showing comparison of results of determinations of calcium in a low-calcium alloy by the 18-hour method and the rapid method. MEH(14)

HISTORICAL & BIOGRAPHICAL (15)

Progress in the Manufacture of Rustless Steels. J. H. MONYPENNY. *Foundry Trade Journal*, Vol. 43, Aug. 7, 1930, page 98.

Abstract of a paper presented to the Liege Mining & Metallurgical Congress. Chrome and chrome-nickel steels were the first kinds used for resisting corrosion. Gives an account of progress achieved and difficulties that have been overcome in producing these steels. VSP(15)

International Nickel. (The Story of the Men Who Built Up This Huge Industry.) A. J. WADHAMS. *Canadian Mining Journal*, Vol. 51, Aug. 29, 1930, pages 838–841.

Historical sketch. WHB(15)

ECONOMIC (16)

Engineering Markets of the World. VII. A. J. LIVERSEDGE. *Engineering*, Vol. 130, Dec. 12, 1930, pages 732–735; Dec. 19, 1930, pages 780–782.

Deals with the situation in the United States. Gives tables and curves showing import figures of U. S. for 1925–1928 and 1913 for comparison. The market in U. S. for engineering products is small because it is largely supplied from home sources. Imports amounted to only 4.3% of total amount consumed. In 1913, United Kingdom was first in supplying iron and steel to U. S. In 1926, Germany was in first place and has held it ever since. Belgium is now in second place and United Kingdom in third place. Table is given showing types of iron and steel imports into the U. S. in 1928. In all classes of engineering products, figures show that the United Kingdom is gradually losing its hold in the American market. Discusses trade situation in Latin American countries. These countries manufacture no iron and steel on a commercial scale and very few other products so there is an immense market for engineering products. Figures are given showing United Kingdom and U. S. engineering exports to Latin America for 1913, 1927 and 1928. In iron and steel, figures show that the United Kingdom is beaten by U. S. by only a small margin. For machinery and electrical apparatus, United Kingdom figures are very low compared to those of U. S. LFM(16)

Manganese and Manganiferous Ores in 1929. LEWIS A. SMITH. *Mineral Resources of the United States*, 1929, Part 1, pages 275–332, *United States Bureau of Mines*, May 19, 1931.

Domestic mines in 1929 shipped 60,379 long tons of high-grade manganese ore, as compared with 46,860 tons in 1928. Shipments of ferruginous manganese ore and manganiferous iron ore amounted to 1,188,258 long tons, a slight increase. Production of spiegeleisen increased from 99,517 tons in 1928 to 137,143 tons in 1929. Imports of manganese ore amounted to 664,266 long tons, an increase of 236,561 tons over 1928. Ferromanganese production at domestic furnaces amounted to 339,205 long tons in 1929. Contains 78 footnote references. AHE(16)

Simplified Account for Welding Shops. WM. T. WHEELING. *Welding*, Vol. 1, Sept. 1930, pages 748–753.

A detailed description of 17 forms and the manner in which they can be adopted successfully for keeping accurate records of a job shop. Ha(16)

Gold and Silver as Monetary Metal. CARL SNYDER. *Mining & Metallurgical Society of America Bulletin*, Vol. 24, No. 219, Apr.-May 1931, pages 49–67.

Paper with discussion. A brief history of the use and value of the 2 metals and a fuller treatment of their influence on modern national economics. The production of gold and silver is greatest in modern days, growing at an almost steady rate just as other commodities, although to an even greater degree. It is stated that the amount of monetary gold had no influence on the economic structure of the world but that the influence was rather one of distribution. Ratio of gold to silver value, propositions to demonetize either material are dealt with and it is shown that the seemingly singular paradox of enormous change in value of money metals had relatively little influence on the price level of commodities which is mostly due to the great inertia in modern industry and an enormous degree of necessary adjustment. In the discussion, more specific conditions are discussed. Ha(16)

Aluminium in 1930. *Metal Industry*, London, Vol. 38, Apr. 17, 1931, page 408.

U. S. production of new aluminum was 102,248 tons valued at $50,961,000. Strong aluminum alloys, electrical conductors and paint saw an increase in consumption of aluminum. A new piston alloy of low expansion coefficient was introduced. The use as roofing and as an exterior ornamental metal is increasing. PRK(16)

The Tin Situation. *Metal Industry*, London, Vol. 38, Mar. 13, 1931, pages 299–300.

Dutch and British producers of tin are coöperating in controlling production which is fixed on a basis of a world production of 126,000 tons. PRK(16)

Copper in Belgian Congo. *Metal Industry*, London, Vol. 37, Aug. 22, 1930, pages 169–172, 197–200.

Description of some of the interests of the Union Minière du Haut Katanga. Taken from a brochure published by the company, entitled "Katanga, the Country of Copper." First metallurgical operations date from 1911. In 1912, production was 2500 tons. Cu deposits are classified in 3 main groups: those of the east, the center and the west. Ore deposits prospected up to Jan. 1929, were estimated at 75 million tons, containing from 3 to 25% Cu. Cu ores are mined at Kambove, Prince Leopold, Luishia, Ruashi, Lukuni, Likasi and Chituru. Ores containing from 6 to 10% Cu are concentrated in three sections: grinding and screening; mechanical concentration; and concentration by flotation. Total output contains on an average 40% of fines and are treated in reverberatory furnaces. Ores in which Cu is widely distributed are treated by leaching, followed by electrolysis. At Antwerp, a large refinery treats crude Cu obtained from Katanga. Two grades are made, containing 99.8 and 99.95% Cu, respectively. The plant has a capacity of 80,000 tons of pure Cu per annum. VSP(16)

Statistic Tables on Aluminum. (Statistische Zusammenstellungen über Aluminium.) *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 2, Sept.-Oct. 1930, pages 159–167.

Comparative tabulation of world production of non-ferrous metals (Al, Pb, Cu, Zn, Sn) from 1909 to 1929, price fluctuations, import duties of different countries, consumption, production of bauxite, import and export. Ha(16)

American Machinist 1930 Inventory of Metal-Working Equipment. *American Machinist*, Vol. 73, Sept. 18, 1930, page 471.

Inventory and classification of various types of furnace equipment in industrial plants. Compares 1920 and 1929. 32% of the equipment is over 10 yrs. old. RHP(16)

Some Aspects of the Iron Ore Situation. F. B. RICHARDS (Hanna Furnace Company). *Rolling Mill Journal*, Vol. 4, Nov. 1930, page 600.

From paper read before the American Institute of Mining & Metallurgical Engineers, Sept. 22–26, 1930. MS(16)

PLANTS & LABORATORIES (17)

Bethlehem's Heat Treatment Shop. S. D. GLADDING (Bethlehem Steel Corp.). *Metal Progress*, Vol. 18, Dec. 1930, pages 74–80.

The author describes the electric handling and heat treatment equipment in this shop. Photographs illustrate details of layout described. WLC(17)

Electrochemical and Electrometallurgical Institute at Grenoble. (L'-institut d'electrochemie d'electrometallurgie de Grenoble.) R. SEVIN. *Journal du Four Electrique*, Vol. 40, Feb. 1931, pages 45–48.

The sketch of the circumstances leading to the establishment of this institution. JDG(17)

Answering a New Demand. J. B. HAMMOND. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 67–69.

The Illinois Steel Co. has built a new 10-in. mill especially for rolling small sections of alloy steel. Ha(17)

The Research Laboratories of the Metallgesellschaft. H. VON HALBAN. *Metallgesellschaft*, Vol. 4, Aug. 1930, pages 3–16.

A detailed description and illustrations of the laboratories of the company in Frankfort a. M. They comprise the analytical chemical laboratory, including ore-dressing shops, the metal laboratory, the technico-chemical laboratory, the physico-chemical laboratory and the colloid-chemical laboratory. Buildings, installation, materials used, equipment, lighting system are described in detail. Ha(17)

Research Institutes for Pure and Applied Chemistry in the United States of America. (Forschungs-Institutionen für reine und angewandte Chemie in den Vereinigten Staaten von Nordamerika.) K. G. STERN. *Zeitschrift für angewandte Chemie*, Vol. 44, Apr. 11, 1931, pages 270–273.

The writer divides the various research institutes into 3 different groups: first, technical societies; second, independent organizations; and, third, industrial organizations. This article covers a relatively small number of those institutions that have been founded for pure and applied research in the United States. It is illustrated by a picture of the projected Mellon Institute building. OWE(17)

The Foundries of the Daimler Company. *Foundry Trade Journal*, Vol. 44, June 25, 1931, pages 433–435, 438.

An article illustrated by 9 photographs and 1 diagram, describing the foundries of the Daimler Company, in which space is devoted to the manufacture, in large and small quantities, of iron, steel, non-ferrous and light alloy castings. OWE(17)

The Foundry of the Midland Electric Manufacturing Company, Limited, An Outstanding Example of Mechanisation. *Foundry Trade Journal*, Vol. 44, June 4, 1931, pages 383–384.

A description of a foundry devoted to the quantity production of electrical switch and fuse gear, in which conveyor systems, etc., have been utilized to assist in production. Illustrated by 3 photographs and 1 diagram. OWE(17)

The Longbridge Works of the Austin Motor Company, Ltd. *Metal Industry*, London, Vol. 38, June 5, 1931, pages 573–574.

Except for certain equipment the whole of the components in an Austin car are manufactured at the factory which uses 120,000 tons of raw material and 50,000 tons of fuel annually. The steel section of the foundry is equipped with 3 Stocks oil fired converters. PRK(17)

Many Sizes and Parts Heat Treated by Brown and Sharpe. E. W. FREEMAN (Brown & Sharpe). *Metal Progress*, Vol. 19, Jan. 1931, pages 61–65.

Very diverse production makes the number and character of furnaces in the Brown and Sharpe hardening establishment large and wide. Photographs show sections of the layout and the author describes the installations of carburizing and annealing, pot type furnaces, small oven furnaces, tempering and high speed steel furnaces. The pyrometric control is described. Need for skilled and intelligent workmen to handle properly this modern equipment is emphasized. WLC(17)

The Foundries of Messrs. Crane-Bennett, Limited. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, pages 239–241.

A description of foundries making black heart castings for malleable pipe fittings and gray iron castings for radiators and boilers for central heating. The article is accompanied by 4 diagrams. OWE(17)

An Electrified Steel Mill. R. H. WRIGHT. *Electric Journal*, Vol. 28, Mar. 1931, pages 146–151.

1930 improvements in the Alabama City plant of the Gulf States Steel Co. include: the replacement of the one existing engine-driven mill with a new larger motor-driven mill and the installation of a 48-inch 3-high universal plate mill, a sheet mill and an increase in substation capacity of 10,000 kvs. Features of each unit are pointed out. WHB(17)

Finishing Industrial and Scientific Meter Parts. THOMAS H. WITTKORN. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 785–788.

Describes cleaning, enameling, and plating procedures followed by the Brown Instrument Co., Philadelphia, Pa. MS(17)

A Carburizing Plant Under Scientific Control. R. G. GUTHRIE & J. A. COMSTOCK. *Metal Progress*, Vol. 19, Apr. 1931, pages 75–80.

The authors outline the functions of a metallurgical control laboratory in the plant of a user of steel. The various laboratory tools are enumerated and their applications to control described. One of the functions of the metallurgist is illustrated in the plan worked out for a new heat treating operation. The metallurgist prepared the layout, specified the furnaces and accessory equipment for the most modern carburizing work. This plant is described in detail. WLC(17)

The Bayonne Foundry. E. S. WHEELER (International Nickel Co.). *Engineering & Mining Journal*, Vol. 130, Nov. 10, 1931, page 488.

A brief description of the Bayonne, N. J., plant of the International Nickel Co. where nickel, Monel metal, everbrite and nickel-resist are cast. WHB(17)

Building for the Needs of Tomorrow. G. G. THORP. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 22–23.

The new 28-inch Strip Mill at Gary, Illinois, in the Illinois Steel Co., has a capacity of 25,000 t./mo. of strip up to 26 in. wide. It is semi-continuous. Ha(17)

Electric Heat Treating Setup Insures Uniformity and Cleanliness. S. D. GLADDING (Bethlehem Steel Co.). *Steel*, Vol. 87, Nov. 27, 1930, pages 43–47.

Description of the plant of the Bethlehem Steel Co., at Bethlehem, Pa., for the normalizing, annealing, quenching and tempering of alloy and C steel bars in sections of 0.25–8 in. and in lengths up to 25 ft. A roller-hearth furnace is used for normalizing or heating for quenching. It consists of a preheating chamber operating at 800° F. and a high temperature chamber. There are 2 pit annealing furnaces, which are divided into 6 zones—3 lengthwise and 2 high. Next in line are 2 car-bottom furnaces, consisting of 2 chambers built in one shell with a common center wall. MS(17)

German Steelmaker Adds to Production Facilities. HUBERT HERMANNS. *Steel*, Vol. 87, Oct. 16, 1930, pages 66, 68.

Describes extensions to the plant of the Mannesmannröhren-Werke at Huckingen, Germany. MS(17)

Stamping and Forging Special Steels. A. H. ALLEN. *Steel*, Vol. 87, July 31, 1930, pages 43–46, 53.
Describes work of the Transue & Williams Steel Forging Corp., Alliance, Ohio, on the development and production of stampings and forgings from Nitralloy and Nirosta KA2. MS(17)

Mass Production of Disk and Wire Type Auto Wheels. A. H. ALLEN. *Steel*, Vol. 87, Sept. 18, 1930, pages 47–50, 52.
Describes equipment and operations of the Budd Wheel Co. MS(17)

Effects Economies in Small Stampings Production. A. H. ALLEN. *Steel*, Vol. 87, Oct. 2, 1930, pages 60, 62, 64.
Describes plant and practice of the Detroit Stamping Co., Detroit, Mich. MS(17)

Heat Treating Pipe Line Couplings. C. B. PHILLIPS (Surface Combustion Co.). *Steel*, Vol. 87, Dec. 25, 1930, pages 43–45.
Describes equipment and practice of the S. R. Dresser Mfg. Co., Bradford, Pa., with special reference to the installation of continuous gas-fired forging and reheating furnaces. MS(17)

Case-Hardened Steel Parts Resist Severe Wear and Shock. J. B. NEALEY. *Steel*, Vol. 87, Sept. 4, 1930, pages 43–45.
Describes equipment and practice of the Tool Steel Gear & Pinion Co., Cincinnati, Ohio, which has developed a special method for carburizing steel parts to depths of $^3/_{16}$–$^1/_4$ in. A carburizing compound developed in its laboratories is used. It is claimed that a uniform hardness is obtained throughout the depth of the case. Most of the work is made from a 0.20% C steel. After carburizing, the C content of the surface is 0.90–1.20% and the scleroscope hardness ranges from 90 to 100. Use 16 large furnaces for carburizing and subsequent heat treatment. MS(17)

The Evans-Wallower Electrolytic Zinc Plant. FOSTER S. NAETHING (Evans-Wallower Zinc Co.). *American Metal Market*, Vol. 38, Apr. 22, 1931, pages 5, 7.
Presented at Annual Convention American Zinc Institute, April 1931. Summary of Tainton high-acid, high-current density process electrolytic Zn plant at Monsanto, East St. Louis, Ill. Details of roasting, leaching, filtering, electrolytic cell room, melting and by products, market for 99.99% Zn. DTR(17)

Buildings for Metalware Pickling and Hot Galvanizing. WALLACE G. IMHOFF. *American Metal Market*, Vol. 38, Apr. 16, 1931, pages 5, 10.
General discussion of relation between floor space, size, shape and building construction materials, drainage facilities, sanitation, lighting, etc., with respect to technique of pickling and hot galvanizing operations. Establishes good practice. DTR(17)

Core-Drying Ovens for Continuous Operation. (Kerntrockenöfen mit durch laufendem Betrieb:) H. ILLIES. *Die Giesserei*, Vol. 17, Aug. 22, 1930, pages 825–826.
Describes an arrangement of the American Radiator Co. in Buffalo and shows the advantages. An oven is described. Ha(17)

Zinc Smelting in Mexico. W. J. JENNI & R. F. SPOONER (American Smelting & Refining Co.). *American Metal Market*, Vol. 38, Apr. 28, 1931, pages 3, 10.
Paper presented at Annual Convention, American Zinc Inst., St. Louis, Mo., April 1931. Complete plant description of sole Zn smelter in Mexico, at Rosita, State of Coahuila. Details of fuel; power; concentrate sampling and handling; roasting with four 20-foot, 12-hearth Skinner roasters; 4-unit 3-section plate type Cottrell treater; Dwight-Lloyd sintering machine, pallet width 63 in., length of wind box 60 feet, with Sintering Machine Corporation suction fan of 75,000 cu. ft. per minute capacity; coke crushing and mix room; retorts and retort furnaces; refinery of 2 reverberatory type liquating furnaces 6 ft. by 24 ft. inside and $3^1/_2$ feet depth of bath; acid plant and condenser concentrator. DTR(17)

MACHINERY & SUPPLIES (18)

Roller Bearings in Swedish Mills. Correspondence from A. WESTGREN (Stockholm). *Metal Progress*, Vol. 18, Dec. 1930, pages 85–86.
The writer describes developments by SKF of the use of roller bearings. WLC(18)

Individual Drives for Table Rolls. W. B. SNYDER (General Electric Co.). *Iron & Steel Engineer*, Vol. 8, Mar. 1931, pages 93–95.
Description of motors and control equipment. WLC(18)

BIBLIOGRAPHIES (19)

Contributions to the Chemistry of Iron, July-September 1930. (Beiträge zur Eisenhüttenchemie, Juli–September 1930.) A. STADELER. *Stahl und Eisen*, Vol. 51, Jan. 15, 1931, pages 71–76.
The author reviews 31 publications referring to steel mill chemistry. GN(19)

Bibliography of the Metallurgical Work of the U. S. Bureau of Mines in 1930. R. S. DEAN. *Bureau of Mines Information Circular* 6449, April 1931, 7 pages.
Over 60 references are given to articles on fundamentals, ore dressing, iron and steel, hydrometallurgy, manganese investigations, rare and precious metals, non-ferrous metals, laboratory apparatus and methods and discussions. AHE(19)

Bibliography of Aeronautics, 1929. National Advisory Committee for Aeronautics. United States Government Printing Office, Washington, D. C., 1930. Cloth, 242 pages. Price 50 cents.
This bibliography of aeronautics for 1929 covers aeronautic literature published from Jan. 1 to Dec. 31, 1929. Citations of the publications of all nations are included in the languages in which these publications originally appeared. The arrangement is in dictionary form, with author and subject entry, and one alphabetical arrangement.
It may be obtained directly from the Superintendent of Documents, Government Printing Office, Washington, D. C.—(19)-B-

Supplement to a Bibliography on Effect of Temperature on Properties of Metals. *Research Publication American Society Mechanical Engineers*, 1931, 26 pages.
This supplement is a continuation of the bibliography prepared by the A. S. M. E.-A. S. T. M. Joint Research Committee on Effect of Temperature on the Properties of Metals published in 1928. The references are arranged chronologically, beginning with 1927 (reference 308) and ending with 1930 (reference 562). Fifty-two references on the Oxidation of Metals at High Temperature are arranged chronologically from 1916 to 1930. RR(19)

A Bibliography on the Cutting of Metals. *Research Publication American Society Mechanical Engineers*, 1930, 63 pages.
Lists 778 references beginning with 1866 and ending with 1930. No attempt is made at correlating or drawing conclusions, but rather the references with a few words of explanation, are arranged chronologically. RR(19)

MISCELLANEOUS (20)

The Question of Safety in Designing. (Zur Frage der Sicherheit in der Konstruktionslehre.) A. THUM. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, June 6, 1931, pages 705–708.
The manner in which strength in structures and machinery is commonly calculated is not suited to modern requirements; it should be modified to allow a consideration of dynamic conditions to the widest extent. The defects of old methods are discussed and directions given for taking account of inadmissable deformations, forcible fractures by impacts and influence of notch effects. Ha(20)

Prevention of Acetylene Explosions and Extinguishing of Acetylene Fires (Verhütung von Azetylenexplosionen und Ablöschen von Azetylenbränden.) A. P. BOTTKE. *Autogene Metallbearbeitung*, Vol. 23, May 15, 1930, pages 157–163.
Acetylene plants should, from the beginning, be laid out and built so that if fire should break out the personnel can get out in the shortest possible time. Fire proof doors between rooms must be provided. Compressed nitrogen and carbonic acid snow have proved to be most effective for extinguishing fires. Sand is of little use; water only if it is possible to get close to the seat of the fire. Water is, however, very useful in cooling the plant by means of sprayers. Ha(20)

Fume Recovery from Electric Furnaces. E. H. DECONINGH (Dust Recovering and Conveying Co.). *Metal Industry*, N. Y., Vol. 29, May 1931, page 221.
The fumes from 3 Detroit electric furnaces of 1 ton capacity, melting a copper-tin-zinc-lead alloy, are recovered by means of a 6 compartment Dracco filter using cloth tubes. Efficiency is 99% and up to 2000 lbs. per day of material containing 70% Zn is recovered. PRK(20)

The Effective Fighting of Acetylene Fires. (Die zweckmässige Bekämpfung von Azetylenbränden.) CARL TIMM. *Die Schmelzschweissung*, Vol. 9, Mar. 1930, pages 56–57.
The origin and causes of acetylene ignition are discussed. Nitrogen and carbon dioxide snow have been found to be the most effective extinguishers. Carbon tetrachloride, on the contrary, should be strictly avoided because of the danger of phosgene gas being formed in the heat of the acetylene flame. Ha(20)

Lead Base Lubricants and Their Use. JAMES EDWARDS. *S. A. E. Journal*, Vol. 28, Jan. 1931, pages 50–52.
The increased gear-tooth pressure required a lubricant that forms an oil film able to withstand this higher pressure. Such film can be provided by a lead-soap-base lubricant composed of lead-soap intimately mixed with hydrocarbon oil. The properties and analyses of 3 different kinds are given. Ha(20)

Use of High Frequency Oscillation in Metallurgy. (L'utilisation des oscillations de haute frequence en Metallurgie.) M. FAYOLLET. *Aciers Speciaux Métaux et Alliages*, Vol. 6, Jan. 1931, pages 11–15.
A critical review of G. Mahoux' discovery of using high frequency current in increasing the depth of nitriding, chromium plating and decarburization. GTM(20)

Directions for the Construction of Correct Water Protectors for Acetylene High-Pressure Apparatus. (Richtlinien für den Bau geeigneter Wasservorlagen für Azetylen-Hochdruckapparate.) H. FRIEDRICH. *Autogene Metallbearbeitung*, Vol. 24, Apr. 15, 1931, pages 111–119; May 1, 1931, pages 127–134.
From the Chemisch-Technische Reichsanstalt, Berlin. All acetylene apparatus must be equipped with arrangements which offer safety against back firing and prevent the danger of oxygen entering into the acetylene containers. Such arrangements usually consist of water-filled chambers in the path of the acetylene. The testing arrangement for ascertaining this safety and the apparatus used in the test are described and the results critically discussed with regard to dependence on water pressure, section and dimension of the water chamber, protection against backfiring (in which case the explosion gases must be conducted into the air immediately) and the arrangement of locating water chambers before every branch of the acetylene container. Ha(20)

Measuring Results of Invar-Wires. (Messungsergebnisse an Invardrähten.) LAMPE NEUMANN & WEBER. *Zeitschrift Vermessungswesen*, Vol. 60, June 1, 1931, pages 315–322.
Several wires of Invar were measured by the National Institutes of Germany, Great Britain and France. The methods are described and the changes in length tabulated. Ha(20)

Brass Fever and Its Prevention. (Das Messingfieber und seine Verhütung.) M. GRUENWALD & E. KALISCH. *Die Schmelzschweissung*, Vol. 9, Apr. 1930, pages 89–90.
Due to the great difference of melting points of the constituents of brass (copper at 1084° C. and zinc at 419° C. with a boiling point at 925° C.), the zinc in the alloy will already have begun to evaporate when brass melts and will burn to zinc oxide which forms a fume and is condensed again as a white deposit in the vicinity. This zinc oxide is injurious to the lungs and respiratory organs and causes fever to those inhaling the vapor. The symptoms are described and, as remedy, hot milk and tea of a certain herb are recommended. Melting of brass should, therefore, be done only in large shops and the vapors exhausted before the melter can inhale them. Ha(20)

Structures, Strength, Continuity. (Struktur, Festigkeit, Stetigkeit.) W. KUNTZE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 7, 1931, pages 285–288; *Mitteilungen deutscher Materialprüfungsaristalten*, Souderheft, XVII, 1931, pages 48–52.
The knowledge of the relation between the inner structure and strength of a material forms the basis for the designing engineer. To a greater extent than is usual at present, the proper conception of strength and its technical determinations should be developed according to structural, rather than according to technological, points of view. It is shown that a conception of strength which is closely related to the structure of the material can offer to the designing engineer a natural and precise means of solving questions of safety and can elucidate many doubts and discontinuities in the stresses and strength of a given piece. A few examples of cohesion, vibration, strength, overload stresses, discontinuities due to changes of section illustrate the views of the author. Ha(20)

Problem of Torsional Vibration Increases with Engine Power. J. ORMONDROYD. *Machine Design*, Vol. 3, June 1931, pages 37–40.
The danger of torsional critical speeds, particularly in modern machines where the ratio of weight to power is made smaller and smaller, is pointed out and explained. The speeds can be calculated exactly and even avoided by proper design. The basic theoretical considerations are explained and illustrated by the example of a Diesel engine. Ha(20)

The Temperature and Velocity Field of a Vertical Plate Giving Off Heat at Natural Convection. (Das Temperatur- und Geschwindigkeitsfeld vor einer wärmeabgebenden senkrechten Platte bei natürlicher Konvektion.) ERNS SCHMIDT & W. BECKMANN. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Feb. 21, 1931, page 227.
Description of tests from which a simple formula for the heat convection from a heated plate to the surrounding air and the buoyancy of the plate in the air can be calculated. Ha(20)

Regulations for Installation and Operation of Factories for the Production of Dissolved Acetylene. (Richtlinien für die Errichtung und den Betrieb von Fabriken zur Herstellung von gelöstem Azetylen.) *Autogene Metallbearbeitung*, Vol. 24, May 15, 1931, pages 152–153.

These German regulations refer to location of factories, buildings and equipment, fire extinguishers and protection for the particular safety of the high-pressure part of the factory. Ha(20)

Proper Lubrication Insures Longer Bearing Life. H. S. TRECARTIN. *Houghton's Black & White*, Vol. 3, May 1931, pages 13–17.

The oil used should be selected for proper weight or thickness, lubricity, purity and freedom from sulphur or acids. It must be clean so that it carries no dirt to the bearing. It should be drained and washed periodically. Ha(20)

Handling Assembly and Tests from an Overhead Monorail System. C. W. PRESTON (Majestic Household Utilities Corp.). *Iron Age*, Vol. 127, April 2, 1931, pages 1084–1088.

From a paper read before the National Industrial Congress, through the auspices of the American Society of Mechanical Engineers. Describes details of operation in handling of materials through the plant of the Majestic Household Utilities Corporation. Cost of operation is lower for the area covered than other systems appeared to offer. VSP(20)

The Manufacture of Slag Brick. R. BELL. *Engineering Progress*, Vol. 11, Nov. 1930, pages 293–294.

Slag from the blast furnace is cooled rapidly as it runs from the furnace. This results in the formation of small glass-like grains. These may then be converted to brick by the steam hardening process which is described. RHP(20)

On the Attack of Metals by Insects. (Ueber den Angriff von Metallen durch Insekten.) O. BAUER & O. VOLLENBRUCK (Kaiser Wilhelm Institut für Metallforschung). *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, page 117.

The attack of Zn by an insect is discussed. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 46. EF(20)

Metal-Destroying Insects. W. MICHAELIS. *Engineering Progress*, Vol. 11, Oct. 1930, page 260.

Abstract of an article by Bauer and Vollenbruck in *Zeitschrift für Metallkunde*, July 1930. Two species of beetle, the Dermestes Peruvianus and the Dermestes lardarius were found to work on lead and tin foil. They did not attack Al, Zn or brass. They usually damage lead pipes. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 46. RHP(20)

New Applications of Ammonia. M. H. MERRISS (DuPont Ammonia Corp.). *Compressed Gas Manufacturers' Association 18th Annual Report*, 1930, pages 28–37.

At present about 72.5% of the synthetic nitrogen of the U. S. A. is employed in agriculture. For other purposes the percentages are: 17% explosives, 12% refrigeration, 20% miscellaneous, and 51% chemicals and acids. Ammonia is revealed as a many-sided chemical. Its uses are: as an alkali, a fuel, a reducing agent, a source of an acid, a fertilizer material and a means of purifying drinking water. The ammonia-chlorine treatment of water is applied in six ways and the source of hydrogen and nitrogen for fourteen different operations among which are welding, cutting, hydrogenation, lighter-than-air craft, brazing, sulphur removal from coke, inert atmosphere for chemical reactions, etc. A bibliography is included. WHB(20)

Radiation from Metals Bombarded by Low-Speed Electrons. F. L. MOHLER & C. BOECKNER. *Bureau of Standards Journal of Research*, Vol. 6, Apr. 1931, pages 673–681.

A small probe surface at a positive potential in a discharge may draw a current of many amperes/cm.^{2} with the potential gradient limited to a thin sheath over the surface. Under such conditions a continuous spectrum is emitted by metal surfaces in Cs, K, and He discharges. With a Cu probe at 7 volts in Cs vapor, the intensity J (λ) remains of the same magnitude between 6200 and 2400 A with a minimum at 5800 and a maximum at 3800. Below 4 volts the spectrum has a high-frequency limit in this range (3000 A for copper at 2.15 volts). On the assumption that this is analogous to a continuous X-ray spectrum, observed limits indicate work functions of 1.95 volts for Cu, 2.1 for Ag, 1.45 for W (all in caesium vapor). The absolute intensity (except for Ag) agrees within a factor of 2 with values computed from the theoretical equation for intensity of the continuous X-ray spectrum. Efficiency for Cu at 7 volts is estimated as 5×10^{-7}. Comparison with published data on photo-electric effect of radiation from electron bombardment of metals indicates that the magnitude of effects below 10 volts can be explained by this continuous spectrum. (20)

Some Notes on Cast Iron Plating Tools. ROGER POWELL. *Iron & Steel Industry & British Foundryman*, Vol. 4, Feb. 1931, pages 161–162.

From service records the essential of a good plating tool appears to be a good chill 1½ to 3 inches deep. CHL(20)

Detonation Temperatures of Acetylene. (Verpuffungstemperaturen des Azetylens.) W. RIMARSKI & M. KONSCHACK. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 5, 1930, pages 100–103.

Several accidents by spontaneous disintegration of acetylene in closed containers under explosion-like phenomena were the cause of an investigation. Experience had shown previously that acetylene in the presence of an iron surface heated to 510° C. explodes at a minimum pressure of 3.05 atmospheres and a flow of 0.4 l./min. The tests showed that the same phenomenon occurred with other materials than iron at considerably lower temperatures. Oxides (rust), in particular, reduce this temperature to as low as 250° C. A table of 31 different materials shows the explosion temperatures. These tests are being continued. Ha(20)

Electrolysis Tests Quickly and Accurately Made. A. V. SMITH. *U. G. I Circle*, Dec. 1930, pages 4–7.

Buried iron pipes and lead cable sheaths are the conductors dealt with in this article, which describes in particular a special truck equipped for the testing of underground metallic structures. Truck designed by Albert F. Ganz, Inc. Equipment and method of its use are described. MFB(20)

Detinning of Scrap Tin Plate. WILFRED W. SCOTT & NELE E. DAVIS. *Industrial & Engineering Chemistry*, Vol. 22, Aug. 1930, pages 910–911.

The recovery of tin from old tin cans and tin-plate material in general is accomplished on a small scale by subjecting the scrap to alternate action of 5% tartaric acid solution and air in a rotating steel drum. The tin tartrate is treated with hydrogen sulphide, regenerating the acid. The detinned scrap contains about 0.1% Sn which is low enough to permit its use in steel manufacture. MEH(20)

Application of Microscopy to an Unusual Manganese Ore-Dressing Problem. *American Metal Market*, Vol. 38, Feb. 5, 1931, page 13.

A microscopic study of a low-grade manganese ore has been completed at the Intermountain Experiment Station of the U. S. Bureau of Mines, Salt Lake City, Utah, in coöperation with the University of Utah. It showed that the manganese was chemically combined with siderite (iron carbonate) and it is therefore impossible to effect a separation of manganese and iron through grinding, followed by flotation or other mechanical method of concentration. A preliminary microscopic examination is not only the quickest and most direct way of reaching the heart of an ore-dressing problem but is frequently the only reliable method available for accurately diagnosing ore-dressing ills. WHB(20)

FOUNDRY PRACTICE & APPLIANCES (22)

Proceedings of the International Foundry Congress at Liege on June, 23-28, 1930. (Compte Rendu du Congres International de Fonderie de Liege 23-28 Juin 1930.) RENAUD. *Revue de Métallurgie*, Vol. 28, Apr. 1931, pages 226–238.

A brief description of the activities of the Congress is given followed by the extended abstracts of the papers presented at the Congress.

Some Physico-Chemical Changes in So-called Pearlitic Cast Irons. (Sur quelques modifications physico-chimiques des fontes dites perlitiques.) A. LE THOMAS. Pages 227–228.

The paper was published in full in the *Association Technique de Fonderie*, Vol. 5, Feb. 1931, pages 46–58 from which it was abstracted.

Simple and Practical Methods for Study of Cast Iron and Checking the Foundry Practice. (Methodes simples et pratiques pour l'etude de la fonte de fer et le controle de la fabrication des moulages. Nouveau procede de metallographie du graphite.) L. F. C. GIRARDET. Pages 228–230.

Test pieces made of the metal run from the cupola cannot be used for determination of the qualities of the castings. Besides the usual temperature control the metal is tested after tapping for shrinkage by Keep method and the depth of chill is measured with a pair of dividers on the end of a broken-off piece of it. On the finished casting the surface hardness is measured and a shear test run on special projections cast on the body of the castings. Much light is thrown on the structure of the graphite by the use of a reagent: 25 cc. HCl, 100 cc. H_2O, 10 g. CrO_3, 5 g. $NiCl_2$. A second etch reveals minutest particles of graphite invisible after an ordinary etch. For simplification of the classification of metallographic characteristics a series of 12 microphotographs with the increasing sizes of graphite, pearlite and the other constituents is shown.

High Strength Cast Irons. (Les Fontes á Haute Resistance. Progres Recents.) R. LEMOINE. Pages 230–232.

The best strength is obtained in irons having a pearlitic structure and ranging in carbon content between 2.5 and 3.4% C. The structure is in its turn dependent on the speed of cooling and on Si content. To assure a uniformly pearlitic structure a carbon lower than 2.7% and Si above 2% is recommended. Under these conditions the speed of normal cooling is without any effect on the structure. Electric furnace is to be preferred to other means for preparation of iron. Several modifications of melting practice are given. The proper ratio between Si and C is kept by the notch test. This is cast and broken. If the chill is the same the ratio is correct. If it decreases the carbon is eliminated slower than silicon and some addition of iron oxide is necessary. The increase of chill indicates the need for some Si addition. Cupola is available for the process either melting an ordinary iron with a large addition of steel scrap or cast iron of an appropriate analysis. In the first case 40 to 55% scrap is used with coke consumption of about 14%. The second method is much more expensive. Low carbon iron made in an electric furnace gives 35–38 kg./mm.^{2} The same but made in a cupola has the strength of 32–36 kg./mm.^{2}

Factors Influencing the Quenching Properties of Cast Irons. (Les facteurs qui influencent les proprietes trempantes des fontes.) A. L. NORBURY. Pages 233–234.

The paper appears to be a summation of the previous papers by the same author: "Constitutional Diagrams for Cast Irons and Quenched Steels," *Journal Iron and Steel Institute*, 1929; "The Effect of Melting Conditions on the Microstructure and Mechanical Strength of Grey Cast Iron Containing Various Amounts of Carbon and Silicon," *Journal Iron and Steel Institute*, 1930. See abstract in *Metals & Alloys*, Vol. 1, Mar. 1930, page 429.

Nickel Cast Irons. (Fontes au nickel. Etudes et applications recentes.) F. RENAUD. Page 234.

A review of the properties of: high strength pearlitic irons, high strength pearlitic irons graphitized in the ladle; hard chill cast irons; non-magnetic irons for electrical uses; corrosion resistant irons, high temperature resistant austenitic irons; irons suitable for heat treatment.

Evolution of Malleable in France. (L'Evolution de la malleable en France.) RAYMOND GAILLY. Page 235–236.

After the war the French manufacturers made a rapid progress in malleable industry following the American methods. At the beginning the quality was much below American standards but the equipment of the plants with laboratories and pyrometric control permitted production of entirely satisfactory material. Two reverberatory furnaces were built in 1922 with the capacity of 10 tons and in 1926–27 the furnaces were enlarged to 20 tons and put on pulverized coal. In the latest years much work was done on application of rotary melting furnaces. Annealing furnaces followed the same line of development and are at the present of the capacity of 30 tons being fired with pulverized coal. The difficulties in obtaining satisfactory help resulted in wide introduction of hydraulic and then of compressed air molding machines. None of the present French foundries use chill casting. The industry is rapidly developing.

Some Remarks on the Foundry Defeat Called Dark Spots. (Quelques remarques sur un default de fonderie "le noir de la malleable.") M. KAGAN & R. DEPREZ. Page 236.

Sometimes on breaking the malleable casting as cast one can observe dark areas which are one of the most common defects of this type of castings. They are caused either by cracking of the casting or by the blowholes present in the metal. Means suitable for elimination of these defects would simultaneously cure the dark spots.

High Strength Malleable Iron. (La malleable á haute resistance.) E. PIWOWARSKY. Page 237.

There are many reasons why black heart malleable is open to more improvements than the white heart. Until a recent date the maximum content of Mn in black heart was 0.2–0.3%. Its increase to 0.4–0.6% considerably reduced the annealing time. With the present practice black heart malleable made in Germany has a tensile strength of 38–43 kg./mm.^{2} and elongation in 60 mm. 11–18% while white heart has 42–50 kg./mm.^{2} and 5.9–6.5% elongation depending on the furnace used for its melting. The time of annealing can be reduced by increasing Si content and decreasing carbon. The author introduced in practice a method in which a considerable improvement in the properties can be obtained by heating the castings at the beginning as high as possible and then keeping the temperature fluctuating just above and below the pearlitic range which greatly increases the decomposition speed of pearlite. Stabilizing action of Cr can be easily overcome by the increase of Si or Ni much improving the final product. Ni-containing irons are less subject to surface oxidation and therefore are probably suitable for making of white heart castings.

A Contribution to the History of Malleable Foundries in the Liege District. (Contribution á l'histoire de la fonderie de malleable au pays de Liege.) Page 238.

Historical sketch showing the influence of English practice on the development of Belgian malleable industry. JDG(22)

Steel Foundry Casts Anvil Block. *Foundry*, Vol. 58, Nov. 15, 1930, page 73.

Describes the production of an anvil block by the Otis Steel Co., Cleveland. The casting is 6 ft. wide, 7 ft. high and 14 ft. long, weighing 15 tons. It was made for the use of the Taylor Forge & Pipe Works, Chicago. VSP(22)

Cast Pipe to Carry Telephone Cables under Harlem River. JOHN TIRRELL (Warren Foundry & Pipe Co.). *Steel*, Vol. 87, Nov. 6, 1930, pages 50, 52.
Abstract of paper read before joint meeting of Newark Foundrymen's Association and Metropolitan Section, American Society of Mechanical Engineers. Describes manufacture of cast-iron pipe of bell and spigot type, 84 in. in diameter. Pipes and curves were poured bell end up; flasks, corebars and patterns were especially made. Ramming was done by hand. A 7- and a 5-ton ladle were used for pouring. MS(22)

Hardening Gray Iron May Have Industrial Applications. A. F. SHORE. *Foundry*, Vol. 58, Dec. 15, 1930, pages 74–76.
Describes tests conducted on hardening properties of gray Fe. Results of hardening gray Fe due to presence of combined C, cast in Fe chill mold, attained hardness of 48 scleroscope to a depth of 1/16 in. It was found that subjecting it to a temperature of 1750° F. for 2 or 3 hrs. the hardness was brought down to 35 scleroscope. Same annealing treatment was applied to an alloy containing 4.50% Ni and 1.50% Cr. The alloy failed to respond to annealing treatment for the purpose of machining. The effect of Ni in gray Fe is the same as in steel. Wear resistance depends not only upon hardness of cylinder walls but also on combined C in the walls. According to author if gray Fe contains free silica or other gritty particles, it becomes the controlling factor in wear resistance tests. VSP(22)

Composition and Properties of Sand for Aluminum Casting. (Zusammensetzung und Eigenschaften des Sandes für Aluminium-Formguss.) A. RODEHUESER. *Aluminium, Hauszeitschrift der V. A. W. Erftwerk*, Vol 3, Jan.-Mar. 1931, pages 75–83.
The sand for molds for casting aluminum should be fine and not contain too much clay in order to give sufficient strength to the mold and a smooth surface to the cast. Good porosity is advantageous but not absolutely necessary. Humidity should be kept low. Instructions for preparation and mixing of different sands and the results of tests are given. Ha(22)

Reconditioning Die Casting Machines. W. E. WARNER. *Canadian Foundryman*, Vol. 22, Mar. 1931, page 12.
A note on the subject, in which the methods which should be adopted in the examination of die casting machines when being repaired are considered. OWE(22)

Permanent Molds and the Influence of Cooling Velocity on Gray Iron Castings. (Ueber Dauerformen und den Einfluss der Abkühlungsgeschwindigkeit bei Grauguss.) EMIL KOETTGEN. Doctor's Thesis published by Giesserei Verlag, Düsseldorf, 1930, 14 pages.
The theoretical bases of gray casting are explained and means are developed to precipitate graphite in fine form. This purpose is carried out in the process by means of permanent molds controlling the cooling velocity. The latter depends on the wall-thickness of the piece, the mold, preheating, heat conductivity of the mold, pouring temperature, etc. All of these factors were represented in curves. The influence of pouring temperature was especially investigated. It could be stated that, with decreasing pouring temperature, the Brinell hardness increased, if the material was always melted at the same temperature. This condition was reversed if it was poured with the same temperature at which it was melted. The origination of the finest structure, eutectic graphite, was examined at increased cooling and at overheating. Recalescent point measurements with oscillograph confirmed the assumption that graphite is precipitated directly from the melt. Overheating of the melt had no influence on this. Some views are discussed with regard to design and economy of permanent forms Ha(22)

Preventing Uneven Chill in Chilled Moulds. *Foundry Trade Journal*, Vol. 44, June 18, 1931, page 414.
An article describing a method which can be used to ensure an even chill on molds. The article is illustrated by one diagram. OWE(22)

Making Pipes in Green Sand. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, pages 237–238.
An article reporting a talk on the above subject, in which a description is given of the production of straight pipes, bent pipes and syphon pots in green sand. A brief discussion is also recorded. The article is accompanied by 7 diagrams. OWE(22)

Sand-Spun Cast-Iron Pipes. *Foundry Trade Journal*, Vol. 43, Sept. 4, 1930, page 161.
Describes Staveley Works of the Staveley Coal & Iron Co. used for the manufacture of cast Fe pipes in sand lined molds by the centrifugal process. The pipes made are of 4, 6, 8, 10 and 12 in. sizes, of the socket and spigot type. Advantages of the process are that the pipe will not chill and annealing is not necessary. Greater strength, toughness and elasticity is gained by the sand-spun process for lesser thickness of metal. VSP(22)

Magnetically-Operated Moulding Machines. An Important British Development. *Foundry Trade Journal*, Vol. 43, Sept. 18, 1930, pages 195–196.
Describes patented magnetically operated molding machines, which use the power from the mains by the intermediary of either solenoids or electromagnets. This was developed by the British Insulated Cables, Ltd. VSP(22)

The Continuous Process as Applied to Malleable Practice. B. R. MAYNE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Oct. 1930, pages 561–576.
For continuous supply of metal for pouring, cupolas are used to melt the cold stock and electric furnaces are used for refining and raising the temperature. Close laboratory control is required. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 86. CHL(22)

Cupola Melting of Brass. T. MAULAND (International Harvester Company). *American Metal Market*, Vol. 38, May 14, 1931, pages 3–4.
Gives details of fuel, lining and patching, lighting of bed, charges, losses and pouring temperature. Advantages of cupola melting are: (a) rapid and economical melting; (b) ease and ability to get hot metal; (c) absence of heat and noise; (d) absence of fumes (except when tapping); (e) low melting loss; (f) quality of product. Process not recommended for melting alloys high in Zn. DTR(22)

Speedier Malleable Melting and Annealing. L. H. MARSHALL. *Metal Progress*, Vol. 18, Nov. 1930, pages 90–94.
The author discusses the 2 phases of malleable manufacture, melting and annealing. Use of soda in melting discussed. Methods of shortening the anneal are given. WLC(22)

The Production of an Aluminium Alloy Casting. E. JACKSON. *Metal Industry*, London, Vol. 38, May 15, 1931, page 508; *Foundry Trade Journal*, Vol. 44, June 4, 1931, page 392.
Paper read before Institute of British Foundrymen, Junior Section, April 25, 1931. Molds should be rammed lightly and vented well. Castings are discolored if left in mold too long. Runners and risers are best dressed off by means of a band saw. OWE+PRK(22)

Core-binders. H. H. EBERT. *Iron & Steel Industry & British Foundryman*, Vol. 3, Sept. 1930, pages 363–364.
Brief review of principal core binding materials; sulphite liquor cores; use of molasses and resin; flour and starch; tar, linseed and other oils; composition of typical mixtures. CHL(22)

DETROIT Rocking Electric FURNACES

Small (250 lb.) Detroit Electric Furnace Pouring Heat of Alloy Steel

These furnaces manufactured in capacities from 250 lbs. per hour to 6000 lbs. per hour, offer unusual economy in the production of grey iron, malleable iron, alloy steel, or non-ferrous castings showing the highest possible quality. The rocking action of the

DETROIT ELECTRIC FURNACE

insures complete homogeneity and uniformity, as well as physical characteristics of a highly superior character in the finished castings. Over 50 DETROIT ELECTRIC FURNACES are in use in melting or duplexing grey iron or alloy steel, and over 400 furnaces are in use in the non-ferrous foundries throughout the world.

We will be pleased to send you complete information regarding these remarkable furnaces.

DETROIT MICHIGAN

FURNACES & FUELS (23)

The Electric Furnace as a Metallurgical Tool in the Steel Industry. CHARLES MCKNIGHT. *Iron & Steel Engineer*, Vol. 8, May 1931, pages 224–227.

Paper read before the Pittsburgh Section, Jan. 21, 1931. The author discusses the uses of the various electric furnaces for melting alloy steel, resistance, indirect arc, direct arc and induction. The necessity for careful and interested operators of such furnaces is stressed. WLC(23)

Various Heat Treatment Furnaces Used in the Manufacture of Telephone Equipment. W. A. TIMM (Western Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 351–368.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, September 1930. Includes discussion. The author describes the heat treating equipment used in manufacture of 25,000 different items and the methods of selection of this equipment. WLC(23)

Electrical Apparatus for the Coreless Induction Furnace. T. R. STANSEL (General Electric Co.). *Iron & Steel Engineer*, Vol. 7, Nov. 1930, pages 519–524.

Refers to power sizes of coreless induction furnaces of 50 kva and greater. Discusses the principle of induction furnace and calculation of various constants. Generators and capacitors for high frequency induction furnace installations are described. WLC(23)

Low Temperature Gas Furnaces for Nitriding and Drawing. JAMES H. KNAPP. *Metal Progress*, Vol. 19, Feb. 1931, pages 38–39, 156; *Steel*, Vol. 88, Feb. 19, 1931, pages 38–40.

A paper presented before the Western Metal Congress in San Francisco, Feb. 16, 1931 and to appear in the Transactions in greater detail and with discussion. The author points out that 2 new features must be built into a gas furnace to operate satisfactorily at 800–1000° F, (a) some method of reducing the spread between the flame and work temperatures, and (b) some means of uniform and rapid circulation. Advantages of the circulation and convection heating at these temperatures are mentioned. A description of a furnace incorporating these features is illustrated with a diagram. The furnace has been satisfactorily operated at these temperatures for 6 months. A study of the temperature uniformity in the furnace is reported. Accessary and control equipment are described. WLC(23)

"Russ" Type Induction Furnace for Making Special Steels. (Four electrique "Russ" à induction pour l'affinage d'aciers speciaux.) *Journal du Four Electrique*, Vol. 40, May 1931, page 176.

A brief description of a furnace particularly suitable for duplex process and using standard or low frequency current. JDG(23)

A Review of Certain Gas Producer Practice. V. WINDETT (Wellman Engineering Company). *Preprint* for May 1931 Meeting, *American Iron & Steel Institute*, 69 pages.

Describes principles of design and operation of modern mechanical gas producers for open-hearth furnace and other use. Especial emphasis is laid on the ability to use low grade, high ash, low volatile coals even though the coal is nearly all fines. Detailed data are given on 23 coals. Some 33 pages of tables and 17 plots are included on performance of producers. HWG(23)

The Industrial Gas Field—Its Activities and Future Possibilities. J. E. WHITE. *Gas Journal*, Vol. 194, May 6, 1931, pages 371–374.

Includes discussion. Paper presented before North of England Gas Managers' Association. Describes industrial possibilities and large gas undertakings, heat treatment of finished forgings, use of gas furnaces and manufacture of parts in gas furnaces. MB(23)

Electric Annealing of Aluminium. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, page 244.

A description of a large resistance furnace for annealing aluminum sheets, manufactured by the General Electric Company and erected at Dolgarrog, Wales, for the Aluminium Corporation, Limited. OWE(23)

Bronze Melted Economically in High Frequency Furnace. J. H. WILLIAMS (Gen. Fire Extinquisher Co.). *Metal Progress*, Vol. 19, Jan. 1931, pages 57–60.

The application of the induction furnace to the production of small bronze castings for fire protection systems is described and discussed. WLC(23)

A Novel Drying Stove. *Foundry Trade Journal*, Vol. 44, June 4, 1931, pages 385–386.

An article illustrated by 2 photographs and 1 diagram and describing a vertical continuous drying stove which is used in a foundry manufacturing the heavier type of casting for automobile work. OWE(23)

The Brackelsberg Furnace at Bingley. *Foundry Trade Journal*, Vol. 44 Apr. 9, 1931, pages 257, 262.

A description of the Brackelsberg furnace which has been installed for Messrs. Clegg and Howgate, Limited, Bingley, Yorks., accompanied by 3 diagrams. OWE(23)

The Theory of Electrical Heating. (Zur Theorie der elektrischen Heizung.) F. WALTER. *Elektrotechnische Zeitschrift*, Vol. 52, July 9, 1931, pages 911–912; *Archiv für Elektrotechnik*, Vol. 24, No. 5, 1931, page 574.

The heating of a body by induction and conduction is determined by the absorption of that energy which the body takes from the electric energy field. The conditions are theoretically investigated and formulas are developed for the calculation of effective resistance, self-induction coefficient and alternating current resistance of iron sheets of definite dimensions. Ha(23)

Ash in Boiler Operation. (Asche im Kesselbetrieb.) FRIEDRICH SCHULTE. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Mar. 1931, pages 67–68.

Paper presented at Düsseldorf, Jan. 7, 1931. Tells how to overcome difficulties and daily problems. An extensive table giving the chemical composition of various slags occurring in iron and steel metallurgical furnaces is printed. MAB(23)

The Design and Operation of Open-Hearth Furnaces. C. W. VEACH. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 15–18.

Cites important landmarks in history of steel making from early work of Siemens in 1857 to first commercial manufacture of basic open-hearth steel by Carnegie, Phipps & Co. in 1888. In 1890 basic open-hearth furnaces produced 90,000 tons of steel in furnaces of 15–35 tons capacity as against present annual production of 30,000,000 tons in furnaces of 300–400 tons capacity. Open-hearth furnaces require 6,500,000 B.t.u. per ton of steel. The author expects improvements in furnace design and combustion control will lower this figure to 5,000,000 B.t.u. Also expects larger number of heats will be obtained in a "furnace campaign." Small, basic open-hearth furnaces now average 450 heats per furnace campaign. By better flame control, minor changes in construction and greater care in safeguarding furnace lining against overheating, the author has achieved over 800 heats per furnace campaign. A comparison was made of three "campaigns" in a 31 ton furnace yielding 1350 heats in 81 weeks under the old system against two "campaigns" yielding 1600 heats in 84 weeks under new practice. Cost analyses show a decrease in maintenance expense from $0.45/ton to $0.322/ton, or a saving of $0.128/ton. There was also a gain in production of 5790 tons over the average rating for 84 weeks. JN(23)

REFRACTORIES & FURNACE MATERIALS (24)

Comparative Tests for Determining Resistance of Fireclay Brick to Thermal Spalling. R. H. HEINDL (Bureau of Stanadrds). *Preprint* No. 64 for June 1931 Meeting, *American Society for Testing Materials*, 9 pages.

Comparison of A. S. T. M. spalling test, test promulgated by U.S. Federal Specifications Board, and modifications of these. It is concluded that the Federal method needs revision. A good method seems to be to heat from one end till that end is at 1400° C., hold 5 hours, cool slowly. Then heat the end again to 850° C. and quench it in 2" of running cold water. Allow to steam in air 5 minutes and reheat for 1 hr. to 850° C. Quench and repeat the cycle till the end is completely spalled, removing from time to time pieces that are so loosened that they will not support the weight of the brick. HWG(24)

Care and Maintenance of Fuel-Fired Furnace Linings in the Nonferrous Foundry. H. E. WHITE. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 1, Nov. 1930, pages 644–653.

Spalling and improper atmospheres are the chief causes for failure of furnace linings. Factors conducive to long life are listed and discussed. CHL(24)

GASES IN METALS (25)

The Adherence and Nature of Hydrogen Absorbed by Platinum Metals. (Haftfestigkeit und Natur des von den Platinmetallen sorbierten Wasserstoffs.) E. MÜLLER & K. SCHWABE (Technische Hochschule Dresden). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 154, Apr. 1931, pages 143–166.

All platinum metals absorb large quantities of hydrogen to the same degree as palladium does, presumably their oxides have been reduced by hydrogen at low temperatures. At low pressure, the H_2 absorbed is liberated in palladium completely, in platinum partly, but not at all in rhodium, ruthenium, iridium and osmium. The authors explain this different behavior as a difference between "mol-absorption" and "atom-absorption." The molecularly absorbed hydrogen (Pd and Pt) is only loosely fixed and dependent on pressure. The atom-absorption phenomena takes place only at the surface and discloses no relationship to pressure (Rh, Ru, Ir, Os and partly Pd, Pt). EF(25)

Gases in Metals. PAUL D. MERICA. *Mining & Metallurgy*, Vol. 12, Apr. 1931, pages 189–191.

Second of a series of discussions by the Institute of Metals Division of the A. I. M. E. The occurrence of blisters on rolled plates or sheet metal, as well as in enameled coatings is due to the presence of gases in metals. Exposure of metals to reducing gases at high temperatures may render metals brittle, notably Cu. Magnetic properties of highly magnetic materials are seriously affected by gases such as H, N and CO. The presence of 0.0002% H in casting renders it porous. Gases are absorbed to a greater extent at higher temperatures that at lower temperatures. Temperature, pressure and the presence of other elements, either in the molten metal or in the gaseous atmospheres, may have a great effect on the solubility of gases because of the effect on the chemical reactions involved. VSP(25)

Remarks Regarding the Influence of Occluded Gas on the Mechanical Properties of Metallurgical Products. (Remarques relatives á l' influence des gaz occlus sur les propriétés mécaniques des produits métallurgiques.) L. GUILLET & J. COURNOT. *Comptes Rendus*, Vol. 192, Mar. 30, 1931, pages 787–789.

A contribution to the discussion of the effect of occluded gas on the mechanical properties of electrolytic products and in particular of electrolytic iron, resulting from a recent paper by Messrs. Guichard, Clausmann, Billon and Lanthony, in which doubt was cast upon the relationship between the remarkable properties of electrolytic metals and their occluded gas content. The authors suggest that further experimentation is required and in conclusion point out that the results referred to by Guichard and his collaborators do not explain the effect of high frequency current upon the hardness of the electrolytic metals. OWE(25)

Investigations on Helium. IX. On the Helium Content in Meteoric Iron and the Accompanying Components of Iron Meteors as well as in Metals on Earth. (Heliumuntersuchungen. IX. Ueber den Heliumgehalt im Eisen und in den Akzessorischen Bestandteilen von Eisenmeteoriten sowie in irdischen Metallen.) F. PANETH & WM. D. URRY. *Zeitschrift für physikalische Chemie*, Sec. A, Vol. 152, Jan. 1931, pages 127–149.

Helium content in iron from 38 different meteors was determined. The quantities amounted to 0.23×10^{-6} and 36×10^{-6} cm. He, except one sample from Savik. The investigations on the accompanying components in meteors mainly confined to troilite. Furthermore schreibersite, pallasite and mesosiderite were studied. No He was found in 2 kinds of Cu from this earth (Michigan), while 2 sorts of Fe (Disco-Greenland and Kassel) contained quantities of He sufficient for computing their geological age. The second part refers to the study of He in meteors in relationship to temperature up to 1000° C. The different behavior of the surface regions and the core is considered and conclusions are drawn to geological age determinations. EF(25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Experiments with Chromium in Gray Iron. T. F. JENNINGS. *Foundry*, Vol. 59, Mar. 1, 1931, pages 93–95.

From a paper read before the American Foundrymen's Association. Investigations show that certain limits exist as to the quantity of Cr that may be added to cast Fe if machinability is to be retained in a given thickness of section. With Fe containing C 2.86%, Si 2.7%, Mn 0.50%, S 0.062%, P 0.794%, the maximum permissible addition of Cr before variation in case of machinability occurred between 0.52 and 0.63%. Transverse strength and deflection is augmented by addition of Cr up to 0.50%. Resistance to atmospheric corrosion is improved by adding over 1% Cr. Considers, also, the effect of Cr on fluidity. VSP(27)

Effect of Composition on Aluminum-Base Die-Casting Alloys. D. L. COLWELL (Stewart Die Casting Corp.). *Preprint* No. 225 for June 1931 Meeting, *American Society for Testing Materials*, 10 pages, 6 references.

The voluminous data obtained by A. S. T. M. Committee B-6 on Die Castings includes results on many specimens that are quite wide of the nominal composition. Half of the alloys under test are outside the limits set. Out of 12 alloys supposed to be made up to certain limits by 5 producers, one producer made only one of the 12 within the desired limits, another only 2, 2 others 6 and 8, and one producer came within the limits on all 12. The data are analyzed with this in mind. An alloy of 1–2% Cu, ¾–2% Si, 1¾–2½% Ni, 2½% Fe, is not as tough in impact as the uncorrected committee data would indicate and those of 0.6% Cu, 11–13% Si, 05% Ni, 2% Fe and 7–9% Cu, 1–2% Si, 1% Ni, 2½% Fe, are tougher. The 11–13% Si alloy is a better alloy than it would be rated to be by the uncorrected figures; it has about 36,000 lbs/in.² tensile, 2% elongation and 3¾ Charpy or 2¾ Izod, all figures for the true composition being appreciably better than the averages that included specimens off in composition. The 8% Cu alloy is also better than the off-composition averages. HWG(27)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Effect of Temperature on Some Properties of Iron-Chromium-Nickel Alloys. N. B. PILLING & R. WORTHINGTON (International Nickel Co.) *Preprint* for A.S.T.M.-A.S.M.E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 347–402, 18 tables, 27 figures, 77 references.

Detailed data on the properties of some 250 alloys of this class are tabulated and plotted. The data were obtained by short-time tensile, regular creep or accelerated creep tests. Short-time tensile tests have close correlation with hot-working properties. Creep tests by different observers are difficult to intercompare. Many observers report data on the basis of an assumed "limiting creep stress," which probably does not exist. Stress for a given rate of flow is a better way of reporting data. Both Fe and Ni are important for good creep strength in Cr alloys, 80 Ni 20 Cr is relatively weak. Castings show better creep strength than wrought metal. This is the more pronounced, the higher the Cr. In alloys with 20 to 30% Cr and 20% Ni the presence of 1/2% carbon gives better creep strength than very low carbon, but in very high Ni alloys, this is reversed. Tungsten has very marked strengthening effect. In alloys with 20% Cr at 1200° F. the short-time tensile strength rises with increased Ni, but creep resistance rises but slightly as Ni increases from 8 to 40%. The trend in cast alloys may be different. Resistance to high temperature oxidation is conferred by Cr and improved by Si. In high Ni alloys, increase of Cr above 30% does not bring much further improvement. Resistance to sulphur gases is increased as Cr, Fe, Si, and Al increase; i. e., as Ni decreases. The attack depends much on the degree of oxidation of the gas, reducing conditions such as presence of hydrogen facilitate attack. Attack may be greater between 1100° and 1500° F. than above or below. Cast 18–8 alloy is generally produced in the ranges Cr 17–20%, Ni 7–10 1/2; Si 1/4–3/4; Mn under 0.65%; C under 0.20%. Design stresses for cast heat-resistant alloys vary widely. For alloys with about 1/2% C the following ranges at 1800° F. are used by different designers, 17 Cr 35 Ni, 290 to 1250 lbs./in.^{2}; 8 Cr 66 Ni, 350 to 1250 lbs./in.^{2}; for 28 Cr 10 Ni, 250 to 1100 lbs./in.^{2}. The vast amount of detailed data packed into this paper makes any abstract inadequate. HWG(29)

Properties of Copper and Some of Its Important Industrial Alloys at Elevated Temperatures. W. B. PRICE (Scovill Mfg. Co.). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 234–244, 12 figures.

Short-time tensile tests, hitherto unpublished, and carried up to 1600° F. in order to get information useful in planning hot forging, extrusion and similar operations, are presented on high purity copper; naval brass; Admiralty; Muntz; 2 and 1; leaded 70:30; low brass; cap gilding; and aluminum brass. Copper and cap gilding were carried above 1800° F. As low as 0.1% Pb in 2 and 1 brass ruins the high temperature ductility. Without lead, ductility increases with temperature. The brittleness of α-brass just below the recrystallization temperature is greatly emphasized by cold-working. Cap gilding (90 Cu 10 Zn) holds its strength well, having 10,000 lbs./in.^{2} tensile at 1100° F. Most of the other alloys have only 5000 lbs./in.^{2} or less at that temperature. The data on pure copper show greater high temperature ductility than do other published data, which is ascribed to the high purity of the material used. HWG(29)

Discussion of Paper by W. B. Price on High Temperature Properties of Copper and Various Brasses. W. H. BASSETT (American Brass Co.). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 245–254. 7 figures, 4 tables, 13 references.

Adds hitherto unpublished data on short-time tests from room temperature to 600° F. on most of the alloys discussed by Price, also on a nickel brass, on 90 Cu 10 Sn, 80 Cu 20 Ni, and on German silvers with 18 and 30% Ni. Alloy of Cu with 5% Zn and 20 to 30% Ni retain half their strength at 930° F. One of 96% Cu, 3% Si, 1% Mn retains half at 750° F. One of 90% Cu 10% Al does not scale at high temperatures and has as high strength at 1650° F. as one with 5% Al has at room temperature. HWG(29)

The Deterioration of Cast Iron on Repeated and Prolonged Heating. C. E. PEARSON. *Foundry Trade Journal*, Vol. 44, Apr. 16, 1931, pages 271–272.

Read before the Newcastle section of the Institute of British Foundrymen. Metals decrease in strength and hardness as temperature is raised but the loss is regained on cooling. Cites results of other investigators. Growth occurs in oxidizing and reducing atmospheres and, also, in vacuo. Decomposition of Fe_3C may be the cause of growth. Other factors causing growth are the size and distribution of graphite flakes. Considers the effect of Mn, P, Ni, Cr and Si. Growth is retarded in Fe which has been superheated prior to casting owing to the form of graphite distribution. VSP(29)

Trends in Engineering Requirements for Metals for the Power-Plant Industry. H. J. KERR (Babcock & Wilcox Co.). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 9–13.

Increase in boiler efficiency is contemplated by increase in steam pressure and temperature, or by use of some other material than steam. Limitations in pressure and temperature can only be raised by use of special steel. High pressure drums, headers, etc., require weldable, ductile material that will stand cold working, obtainable in large, thick plates and of 100,000 lbs./in.^{2} tensile, stable for indefinite service at 750° F. High pressure tubes exposed to radiant heat must stand 1000° F., showing a creep rate of not over 1% in 100,000 hrs. at 10,000 lbs./in.^{2}, and be stable, be readily manufactured, be good for fusion welding, withstand contact with steam and boiler water, sulphur gas corrosion and stand some cold working. Carbon steel superheater tubes behave well to 850° F. with proper design, but temperatures of 1200–1300° F. are desired and the tubes should not at those temperatures, exceed the creep rate at the load given above for high pressure tubes. Other requirements are about as for those tubes, extended to 1300° F. Stability up to 1500° F. is wanted. Superheater headers not subjected to gas temperatures have much the same requirements as for high pressure tubes. For binary cycles, with mercury or other material beside water, tube heating elements have the 1300° F. requirements above stated for superheater tubes save that the limiting creep stress is 5000 lbs./in.^{2}, and the elements must resist corrosion by the material used. Soot blowers, hangers and some baffles should stand up when exposed to combustion gases at 1700–1900° F., but there is no rigid stress requirement. These metallurgical requirements are nearing a technical solution, but to pay the power plant for their use, they must be available at a cost that will return interest on the investment. HWG(29)

A Note on the Silver Rich Aluminium-Silver Alloys above 600° C. T. P. HOAR & R. K. ROWNTREE. *Metal Industry*, London, Vol. 38, May 8, 1931, pages 481–482.

Using 99.95% Al to make Ag-Al alloys up to 14.34% Al, thermal and micrographic examination showed the solidus to have 2 breaks: 6.2% Al and 779° C., and 10.8% Al and 729° C. The following table gives the phase boundaries:

	Boundary Determined		
% Al	$\alpha/\alpha+\beta$	$\alpha+\beta/\beta$	$\beta+\gamma/\gamma$
5.02	770–775° C.		
5.41	712–721		
6.01	603–625	777–779° C.	
6.90	.....	689–698	
7.40	.....	643–647	
9.50	.....	.....	675–689° C.

Wrought-Iron and Wrought-Steel Pipe and Tubing. Report of Sectional Committee, A. S. T. M. H. H. MORGAN, Chairman. *Preprint* No. 27 for June 1931 Meeting, *American Society for Testing Materials*, 2 pages.

Various specifications are being prepared. A sub-group is to report in June in regard to allowable stresses in piping for temperatures above 750° F. A formula has been adopted for use in setting up schedules for pipe wall thickness for various pressure-stress relations. HWG(29)

Effect of Temperature on the Properties of Nitrided Alloys. O. E. HARDER (Battelle Memorial Institute). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 463–485, 10 tables, 5 figures, 38 references.

The nitride case retains its high hardness when tested hot up to at least 750° F. It retains full hardness after 200 hrs. at 840° F. and retains 55 to 70% of its initial hardness after heating 1 hr. at 1500° F. and cooling. Samples nitrided at the higher temperatures, initially not quite so hard as others, retain a greater percentage of their hardness. A core for a die casting machine used with an Al Si alloy at 1150° F. remained file hard after producing over 125,000 castings. At 930° F. the test hardness is higher than that of high speed steel. Little data are available on the high temperature properties of the nitriding steels. Since these contain Cr, Mo and Al their creep resistance would be expected to be good. A 0.25% C, 0.80% Mo, 1.20% Al steel without Cr gave 73,000 lbs./in.^{2} tensile at 1200° F. on short time test. A nitrided Cr-Al steel is reported as stretching 0.002 in. per inch. at 1000° F. under 10,000 lbs./in.^{2} load, in 4000 hours, then showing no further flow for an additional 5000 hrs. Nitride cases do not stand up in contact with combustion products of ethyl gas, but make good valves for use with straight run gas. Seizure of unlubricated coating surfaces at 750° F. is avoided with nitride cases operating against itself or several other materials. Nitrided steels have worked well in steam valves as high as 1000° F. with high pressures. In the oil industry nitrided pump plungers work without pitting in "sweet" oil at 750° F. and 900 lbs., but are attacked by "sour" oil. General discussion is included of many room temperature properties of nitrided steels. HWG(29)

Heat Resistant Steels, Their Properties, Production and Application. (Oxydationsbeständige Stähle, ihre Eigenschaften, Herstellung und Anwendung.) E. HOUDREMONT. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 206.

High-Chromium Steels for Extreme Service Conditions. C. E. MACQUIGG (Union Carbide & Carbon Co.). *Preprint* for A.S.T.M.-A.S.M.E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 432–449, 6 tables, 20 references.

The Fe–Cr–C system is quite similar to the Fe–C system, save there is no analog to gray iron. The critical cooling rates are very different and the temperature from which the steel is cooled has more effect. The ratio of Cr to C is important. With less than 10 Cr to 1 C hardening occurs about as in carbon steel; with higher ratios, greater hardening occurs. There are 4 groups of commercially important high Cr steels: (A) Cr 5 to 7%, C below 0.3%; (B) Cr 12 to 16%, C below 0.10% in rustless iron, about 0.35%, in cutlery, about 2% in abrasion-resistant steels; (C) Cr 16 to 20%, C around 0.20% or under for wrought metal, about 0.80% for castings; (D) Cr, 25 to 30%, C around 0.35% or under for wrought metal, up to 1% in castings and to 2 1/2 or 3% for wear-resistant castings. Steel of class A, with 0.10% C, 0.34% Si, 0.79% Mn, 5.56% Cr, held 3 hrs. at 1650° F., air cooled then given a short time test at following temperatures, gave the following results.

Temp.	Tensile lbs./in.^{2}	Yield lbs./in.^{2}	Elong. % 2"	Red. Area %
Room	178,000	120,000	16	56 1/2
570° F.	185,000	147,000	12	43 1/2
750° F.	186,000	140,000	19	61
930° F.	164,500	120,000	15 1/2	56
1110° F.	70,700	....	19	75 1/2
1290° F.	27,500	....	35	91 1/2

With low enough carbon all 4 groups of steels are workable, group D forms into seamless tubing more readily than lower Cr steels. Room temperature, strength, thermal expansion and thermal conductivity, electrical resistance and corrosion resistance are discussed. Holding alloys with over 19% Cr at 750° to 1110° F. causes brittleness when cooled to room temperature, though the alloys are tough when actually in that temperature range. It can be removed by an anneal above 1290° F. The great resistance to oxidation and to attack by sulphur at high temperatures gives these alloys great value. They will not stand strongly reducing conditions above 1920° F. Comments on melting and casting practice are given. The problems resemble those of a steel foundry with the difficulties intensified. HWG(29)

On Vapor Tensions and Activities of a Volatile Component in Binary Alloys at Elevated Temperatures. (Ueber Dampfspannungen und Aktivitäten eine flüchtigen Komponente in binären Metallegierungen bei höheren Temperaturen.) K. JELLINEK & G. A. ROSNER (Technische Hochschule Danzig.) *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 152, Jan. 1931, pages 67–94.

The vapor tensions of the binary alloys of Pb-Cd, Sn-Cd and Cu-Cd were determined between 500° and 700° C. and over the concentration range from 10–60 mol. %, while the Cu-Zn alloys were investigated between 600° and 800° C. The activity coefficients of Cd and Zn with reference to the systems investigated were established. The data gained on Cd in Sn and Pb-alloys are compared with the values of Taylor (*Journal American Chemical Society*, Vol. 45, 1923, page 2865). The evaporation heat and the mixing heat of Cd and in Zn with reference to the systems mentioned above were computed. EF(29)

Metallurgical Requirements for High Temperature Piping. F. W. MARTIN (Sargent & Lundy). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 14–22; *Heating, Piping & Air Conditioning*, Vol. 3, Aug. 1931, pages 673–677.

Steam plants are in operation in the U. S. at 1200 lbs. and 750° F., some under construction will run at 1400 lbs., 850° F. An experimental plant at 400 lbs., 1000° F. is building. (This uses 18–8 pipe and fittings.) In Europe, as high as 3200 lbs. at 700° F. is used. Creep is not important in piping; it is only necessary that the bursting point is not reached. 2 or 3% creep in 200,000 hrs. would be permissible. Seamless steel tubing is used up to 750° F. Cast or forged steel is used for fittings up to this temperature. The cast steel must not be given a liquid quench. For higher temperatures, a Cr-Ni cast steel is used that is as strong at 1000° F. as carbon steel is at 750° F. Differential expansion and galling are important in valves. Cast iron or nitrided steel each against itself and stainless steel against nitrided steel, resist galling. The seat ring must stand at least 9000 lbs./in.^{2} at operating temperatures. Materials for stems must machine well and resist corrosion. The valve body and bonnet, as well as the pipe sections are held by studs with nuts on each end. High carbon bolts become brittle. A 0.45 C, 1.50 Ni, 0.70 Cr heat-treated steel serves well. Nuts are usually carbon steel. WAT+WHG(29)

Thermal Expansion of Metals. N. L. MOCHEL (Westinghouse Elec. & Mfg. Co.). *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 Meeting, *American Society for Testing Materials*, pages 509–544, 9 figures, 21 references, 10 tables.

This paper contains 20 pages of tabulated data on thermal expansion of metals and on ferrous and non-ferrous alloys of all sorts, conveniently arranged for reference. Some hitherto unpublished data are included. After a general discussion, typical expansion curves are shown. Many engineering examples of difficulties met because of thermal expansion are cited. To plug holes in retorts, high Ni high Cr steel, of higher expansivity than the retort body, is used for high stress. Chilled surface iron rolls have been assumed to have trouble due to greater expansivity of chilled iron, but recent data indicate similar coefficients for white and gray iron. Piston and cylinder materials and clearances are discussed. Dilatometric methods of study throw light on metallurgical problems. Ingot and forging "clinks" are thermal expansion troubles. Low expansivity, Invar-type steels are discussed. HWG(29)

Pipe Lines for High-Pressure Steam. L. PERREAU. *Engineering and Boiler House Review*, Vol. 44, Mar. 1931, pages 574, 576, 578, 580.

This article is based on notes on design and construction dealing with French practice. Tests have shown that, for saturated steam, the temperature of the wall differed from that of the steam only by about 0.5 to 1° C. For ordinary pressures and temperatures not exceeding 250° C., a formula for calculating the necessary thickness of the pipe is given as

$$e = \frac{D}{2}\left(\sqrt{\frac{R+p}{R-p}} - 1\right) \text{ or } e = \frac{pD}{2R-p}$$

where D is the internal diameter of the pipe (determined from the necessary volume of the steam to pass in a certain time), e is the thickness, p is internal pressure, R is the working stress. The latter must be chosen with regard to the variation in strength with temperature, according to $R_1 = R - 0.12(t - 325)$, where R is ultimate strength at normal temperature, R_1 at temperature t ° C. (for all temperatures from 325° to 500° C.). The methods of joining pipes together with separators are illustrated and figures given for Continental practice of safety coefficients. A diagram is added for elastic limit and ultimate strength of steels up to 500° C. Ha(29)

Spectral Distribution of the Energy Radiated from Metallic Surfaces at High Temperatures. G. R. GREENSLADE. *Heating, Piping and Air Conditioning*, Vol. 3, Jan. 1931, pages 50–58.

This paper contains scientific information on the subject of thermal radiation from metallic substances, from 1500° to as high as 3750° F. The test specimens were heated electrically in a sealed water cooled vacuum chamber. A comparison of the radiation of the metals tested is given in the accompanying chart. The value, K, is a constant depending upon the intensity of radiation and current applied. It was found that the total radiated energy as well as the form of the wave length-energy curve varied with the purity of the metal. WAT(29)

Corrosion and Heat Resistant Nickel-Copper-Chromium Cast Iron. J. S. VANICK & P. D. MERICA. *American Society for Steel Treating*, Vol. 18, 1930, pages 923–942; *Bulletin* No. 208 of the *International Nickel Company*, 11 pages.

Data and graphs are given for tensile strength up to 1100° F. on two types of cast iron: plain and heat resistant. Heat resistant, C 2.75–3.00, Si 1.25–2.00, Mn 1–1.5, Ni 12.0–15.0, Cu 5.0–7.0, Cr 1.5–4.0 percent. Data on corrosion resistance are given for a number of corrosive reagents. Data on oxidation and growth of these two types of cast iron are given at 1500° F. After 40 cycles of heating and cooling (8 hours per cycle at 1500° F.) the heat resistant cast iron showed no growth or effects of oxidation. The alloy cast iron has the machinability of plain cast iron as well as its physical properties. The thermal coefficient of expansion is 50% greater than plain cast iron (similar to that of bronze) for temperatures up to 600° C. The alloy cast iron is non-magnetic and has a high electrical resistivity (1¼ % of copper conductivity). This material is unusually well suited to welding by arc or acetylene and by the use of filler rod of the same composition. See also *Metals & Alloys*, Aug. 1931, page 141. WAT(29)

The Resistance of Ordinary Steel at High Temperatures. (Sur la résistance à chaud des aciers ordinaires.) L. GUILLET, J. GALIBOURG & M. SAMSOEN. *Comptes Rendus*, Vol. 192, Apr. 13, 1931, pages 861–863.

The authors describe an investigation involving the use of a modified Martin's extensometer designed by them and described in *Comptes Rendus*, Vol. 188, 1929, pages 1205–1208. In the present investigation a series of boiler steels have been tested and values for two mechanical characteristics of the steels at temperatures of 225°, 325°, 425° and 525° C., respectively, are tabulated. The 2 characteristics referred to are known as (1) the limit of instantaneous extension proportional to load (la limite des allongements instantanés proportionnels aux efforts)—when passing from one load to a higher, observations are made of the instantaneous extensions which, for loads between zero and a certain limiting value, are proportional to the excessive load which has just been applied, but are not proportional to the excessive load if and when loads exceeding this limit have been reached, and (2) the limit of instantaneous extension without creep in relation to time (la limite des allongements instantanés sans écoulement en fonction du temps)—after the instantaneous extension has been measured, provided the load exceeds a certain limiting value and is continuously applied to the sample under test, the sample extends continuously with time, but ultimately extension reaches a limit at which it stops. The authors submit that the following generalization has been proved—namely, that properly speaking, a true elastic limit does not exist, even for steels at ordinary temperatures, the apparent permanence of dimensions after a slight load has been applied being an illusion resulting from the imperfect sensitivity of our measuring instruments. OWE(29)

LEACHING (30)

Extraction of Soluble Copper from Ores in Leaching by Percolation. JOHN D. SULLIVAN & KENNETH O. BAYARD. *Bureau of Mines Report of Investigations* No. 3073, Apr. 1931, 43 pages.

The physical nature of the rock, its porosity, degree of kaolinization and sericitization, and the amount of natural slime determine the amount of solution that will be retained, and the difficulty that will be found in washing out the soluble salts. The rate of removal of soluble copper decreased with increases in the amount of slime present and increased only slightly with temperature. Wet charging the ore into the vat was advantageous. In washing the cycles of submergence and draining should be as close to each other as possible consistent with fairly thorough mixing of the copper sulphate in the wash solution and thorough draining of the solution. The copper sulphate concentration was greater at the bottom than top of the ore column. Circulating the solutions increased extraction rates. Piston-displacement washing removed copper more rapidly than batch washing but the volume of wash solution required was greater. Downward and upward percolation of wash solutions gave virtually identical extraction rates. Less copper sulphate was precipitated in the ore when the impregnating solutions were acidic. AHE(30)

Factors Governing the Entry of Solutions into Ores during Leaching. JOHN D. SULLIVAN & ENRIQUE OLIVAR OSTREA. *United States Bureau of Mines, Technical Paper* 498, May 1931, 23 pages.

Replacing the air in the voids within pieces of Warren unweathered ore with SO_2 increases the rate of solution penetration. AHE(30)

Factors Involved in the Heap Leaching of Copper Ores. JOHN D. SULLIVAN. *U. S. Bureau of Mines Information Circular* 6425, Apr. 1931, 12 pages.

Enough solution cannot enter a rock at one time to dissolve the Cu minerals completely unless the Cu content is very low. Frequent renewals of solution and much time are required. In heap leaching with oxidized ores the slowest step is probably the removal of the soluble salts. If the Cu exists as sulphide (chalcopyrite excepted) about 20 days will be required for complete dissolution of the Cu. The rate of dissolution of any Cu mineral by a given solvent cannot be markedly changed. Displacing air in heaps with SO_2 from waste smelter gases increases the rate of solution penetration. Finer crushing or recirculation of solutions (if containing some free acid) speed extractions. AHE(30)

REDUCTION METALLURGY (31)

Smelting in the Lead Blast Furnace. Handling Rich Charges. VII. Methods of Charging, Rate of Subsidence of the Charge, and Accretions Made. G. L. OLDRIGHT & VIRGIL MILLER. *U. S. Bureau of Mines Report of Investigations* 3094, Apr. 1931, 11 pages.

Under the conditions of operation at Kellogg, Idaho, a fusible charge is employed containing about 50% Pb that is more difficult to desulphurize than is a poorer charge, and is also more semi-malleable at softening temperatures. A furnace column 7–11 feet high is used. A fast rate of smelting without too great a loss of Pb in the slag is obtained using 9–12% coke in the charge. The rate of subsidence at any one spot in the furnace is fairly uniform for the larger part of the time, although the rate of descent of different sections is vastly different. The sudden descent of the column toward the slag-tap end of the furnace into a space left vacant by the charge smelting away under it, usually causes a sudden increase in the Pb content of the slag issuing from the furnace. Accretions on the shaft walls may be formed by accumulations of volatilized material from the tuyères and residual matter left by the descending charge. At Kellogg these are thickest above the normal level of the top of the charge. The sulphide content (particularly of Zn) increases fairly steadily from the top of the accretion to a little lower than the junction of the 2 tiers of H_2O jackets. From this point down sulphides decrease to a normal slag at the tuyères. Accretions in the crucible start from the top and build downward. They form early and rapidly. They are predominantly sulphides, ZnS being the most notable. The volume free of accretions in which the molten Pb collects is at the bottom of the crucible, and there are but few channels through the accretions to connect this free space with the molten charge at the tuyères. AHE(31)

Iron-Ore Reduction in the Hot-Blast Furnace. WM. MCCONNACHIE. *Iron & Steel of Canada*, Vol. 14, Feb. 1931, pages 21, 42–43.

An article taken from *Iron & Coal Trades Review*, dealing with a study of the conditions obtaining in blast furnaces using as fuel the dry-burning bituminous coal in general use in Scotland, which furnaces, while not having large outputs, can produce pig-iron with a much less consumption of coke carbon—fed as raw coal—than any other. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 91. OWE(31)

Vanadium Recovery from Titaniferous Iron Ore. BJÖRN P. F. KJELLBERG. *Engineering & Mining Journal*, Vol. 131, May 25, 1931, page 460.

An outline of a wet process for extracting vanadium from titaniferous iron ores and concentrates, with the production of vanadium pentoxide and a residue which when melted directly, yields a high-quality steel and a rich titanium slag. Titaniferous iron ores containing vanadium are particularly suited for direct steel production. To the solution obtained by cold leaching of the calcine sufficient aqueous solution of sulphur dioxide is added to permit precipitation of the vanadium compounds with lime. The precipitate analyzing about 40% V when dried, carries a small amount of sulphur which may be expelled by calcining prior to the manufacture of ferro-vanadium. Pure vanadium pentoxide is being extensively used as a catalyst. Its preparation is outlined. WHB(31)

A Practical Method of Solving the Emergency Manganese Problem. C. H. Herty, Jr. *U. S. Bureau of Mines Report of Investigations* 3107, May 1931, 7 pages.

The use of Mn-Si alloys which may be produced from domestic Mn ores for deoxidation, would decrease the ferro-Mn requirements of a very large tonnage of our steel by 60–80% and in some cases 100%. The open hearth heats made with these alloys have been of excellent quality. The tonnage of ferro-grade ores made available by the Bureau of Mines' ore dressing studies, combined with the products resulting from such processes as those developed by the Bureau of Mines and by Bradley for Cuyuna ores, should easily fill our reduced ferro-Mn requirements when Mn-Si alloys and ordinary spiegel are used in the way described in this report, thus making the country independent of foreign ores. AHE(31)

The Wälz Process. I. Metal Volatilization as a New Assistant Process for the Treatment of Complex Copper-Zinc-Lead Ores. William E. Harris. *Canadian Mining Journal*, Vol. 52, May 22, 1931, pages 525–529; **II. Features of a Wälz Plant, and Its Application to the Copper-Zinc-Lead Ores of Eastern Canada.** May 29, 1931, pages 546–550.

A discussion of the sale and treatment of the concentrates. The Wälz process is carried out in a rotary kiln with a mixture of raw concentrate and solid fuel, the latter serving for reducing purposes. Lead and zinc are freed from the oxide or sulphide compounds and volatilized. An oxidizing atmosphere is maintained above the charge in the kiln so that escaping metallic vapors and the carbon monoxide are burned right above the feed. The essential feature of the process is the fact that the zones where the reducing reactions are taking place are superimposed over the whole length of the reaction zone. The Follsain process is another volatilization process, recently brought forward and carried out in a rotary kiln. It is similar to the Wälz process except in the fact that reaction air preheated to 600–800° C. is added to the process instead of cold air. II. A longitudinal section and cross section shows the simplicity of a Wälz plant. It consists of 3 main sections: the crushing, proportioning, mixing and feeding apparatus; the rotary kiln itself with incidental heating appliances; and the gas main with equipment for precipitating the oxide. For precipitating the oxides, Cottrell plants as well as the usual bag houses have given good results. Some existing plants are treating materials in the form of a slurry. For uniform working close observation is necessary on the temperatures at the different points in the kiln. Application of the process by the Base Metal Extraction Co. on a mixed copper-zinc concentrate from an Eastern mine yielded a sinter containing only 54% Zn (96% recovery). The following claims are made for the process: (1) it permits the treatment of mixed copper-zinc concentrates; (2) it eliminates the difficulties resulting in the formation of "insolubles" in roasting and reduces the roasting to the simple elimination of sulphur; (3) it recovers the precious metals with the copper where they are paid for; (4) it reduces the cost of subelectrolytic treatment of the zinc fume and (5) it appears to be the only volatilization process that has stood the test of commercial application. Flowsheets for the treatment of Zn-Cu-Pb concentrate with volatilization as an auxiliary process as well as the main primary process are shown. WHB(31)

Compendium of Metallurgy. (Precis de metallurgie.) H. Pécheux. J. B. Bailliere et Fils, Paris, 1931. Paper, $4^3/_4 \times 7^1/_2$ inches, 650 pages. 4th edition. Price 35 Fr.

A general survey of fire and electric smelting of metals. It is printed on a very poor paper and the 167 illustrations are either like old wood cuts or, as in the case of the few photomicrographs, badly blurred.

There is nothing especially complete or up-to-date in it, even if it is a new edition. Apparatus for determination of carbon in steel by wet combustion in chromic acid is illustrated, and the Cowles electric furnace for making aluminum bronze is shown as if these were in metallurgical use today.

This comes close to being the poorest excuse for a book on any branch of metallurgy we have ever seen.—H. W. Gillett (31)-B-

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Some Developments in the Use of Zinc Pigments. H. A. Nelson (New Jersey Zinc Company). *American Metal Market*, Vol. 38, Apr. 22, 1931, pages 5, 10.

Presented at Annual Convention American Zinc Institute, April 1931. Covers entire field of uses for Zn pigments. DTR(32)

Tunnel Furnace for Enameling. C. B. Phillips. (Surface Combustion Co.). *Iron Age*, Vol. 126, July 17, 1930, pages 159–161.

Discusses vitreous enameling as practiced by the American Stove Co. Vitreous enameling includes dipping, spraying, drying and burning. The necessary units were built by the Surface Combustion Co. The furnace is 120 ft. long, the conveyor units are 187 ft. overall and the furnace is divided into 2 heating chambers. Each section is divided into heat interchange, preheat, heating, heat interchange and cooling. Sheet steel after pickling and dipping in ground coat enamel is burned on at 1600° to 1800° F. and the white coat at 1400° to 1600° F. Firing is done by gas burners. The installation has reduced labor and fuel costs, eliminated separate drying process and cut percentage of rejects. VSP(32)

Coating with Sound-Damping Materials and Rust Removing Agents (Das Auftragen schalldämpfender Materialien und Entrostungsmittel.) A. H. Feige. *Automobiltechnische Zeitschrift*, Vol. 34, June 10, 1931, pages 382–383.

The all-steel bodies for automobiles which have recently come into use have the disadvantage of beginning to vibrate badly after a certain speed is reached and in resonance with vibrations of motor, unevennesses of road, etc. This may be eliminated if a very viscous asphalt lacquer or tar-oil product, sometimes mixed with sawdust, is sprayed on. This spraying may include the whole inner surface, or only parts of it, or even just the corners. The viscous liquid can be sprayed on without heating under a pressure of 4 atmospheres with spraying guns having nozzles of at least 3 mm. diameter under 4 to 5 atmospheres air pressure. Spots of rust can be removed by spraying with a de-rusting agent such as deoxidine with ordinary spraying apparatus. The correct treatment of parts and the required procedure are described. Ha(32)

Method of Preparing Sheet Metal for Finishing. H. M. Hagy (Wanger Elevator Mfg. Co.). *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, page 802.

First all rust spots and scratches are sanded with No. $2^1/_2$ emery cloth. The metal is washed with gasoline, benzine or naphtha. If a composition molding is present, it is washed with a solution of 2 pt. vinegar and 1 pt. H_2O. Scratches, pits and welding spots are then filled up with a paste of dry white Pb and shellac, which, after drying, is sanded down to the metal surface. After wiping clean, a thin coat of an oxide primer is applied, baked at 350° F. for 2 hr. and then sanded with No. 000 sandpaper. MS(32)

Choice of Pigments for Anti-Rust Paint Coatings. (Zur Wahl der Pigmente für Rostschutzfarben.) J. Schneider. *Korrosion und Metallschutz*, Vol 7, Mar. 1931, pages 60–61.

Review of the present state of non-metallic coating technique. EF(32)

Ramet Toolpak

The Ramet Toolpak consists of five small but sturdy Ramet tipped tools, a rugged tool holder and a special grinding wheel, all packed in a finely finished wooden case.

Heretofore the advantages and economies of Ramet tools have been available only to large production plants because of the great cost of special tool designs. The Ramet Toolpak overcomes this limitation by providing a number of inexpensive Ramet tool bits of various shapes to handle a wide variety of work.

An important innovation in these Ramet tool bits is the use of shanks made of a special metal having practically the same coefficient of expansion as Ramet. This metal was developed by Dr. C. W. Balke, Director of Research, Ramet Corporation of America, North Chicago, Ill., and overcomes many of the difficulties encountered in the use of steel shanks because the Ramet tip is not under strain. This special metal also has great advantages in the manufacture of large Ramet tools, especially those having tips of unusual size or shape.

Two right hand, one left hand, one round nosed and one grooving tool contained in the Ramet Toolpak adapt it to the varied jobs of ordinary shops.

In order that longer tool life will be had, a tool holder specially designed to give the proper support and top rake is included in the set.

Ramet tools should be ground on suitable wheels in order to get a keen cutting edge and to minimize the amount of metal removed in sharpening. A special grinding wheel which will fit practically all bench grinders is furnished with the Toolpak so that the Toolpak is complete in every detail.

New Core Oven

The world's largest core oven with a capacity of 800 tons of cores per day, built by the Foundry Equipment Company, Cleveland, Ohio, uses the roller conveyor system, permitting the handling of heavy cores with a minimum of core plate thickness and weight, core breakage practically eliminated and waste oven volume reduced to a minimum.

Approximate dimensions are 235 feet long, 11 feet wide and 20 feet high. The oven contains five tiers or passes each provided with roller conveyors designed for high temperature operation. Lighter core plates are used as the roller conveyor provides practically a continuous support regardless of size. Core plates are moved through the oven by means of pusher mechanism operating directly on the plates. Each tier has a variable speed transmission so that the baking time can be varied as desired.

The oven is heated with four large quadruple heaters located outside of the oven. They are oil fired and automatically controlled. The hot gases from the heaters are delivered to the main oven chamber through a series of ducts. Part of the gases are exhausted from the oven, but the great portion are returned to the heaters to help in the diffusion of the hot gases from the combustion chambers and are then recirculated.

A unique loading and unloading arrangement is incorporated. The cores move on roller conveyors from the core making stations to the loading end of the oven. The lower tiers of the oven are served by a pneumatic elevator, while the cores which go to the three upper tiers are raised by means of an inclined elevator having an automatic locking device to assure perfect alignment of the core plates as they pass from the elevator to the oven rollers.

At the unloading end, the cores are lowered to the floor level by means of an elevator. As the elevator reaches floor level cores are automatically ejected from the oven. The entire system interlocks and is automatically controlled.

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy.

Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given.

Information about this service may be secured by writing to the Patent Department, METALS & ALLOYS, 810 Eighteenth Street, Washington, D. C.

United States Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Note: Numbers of Reissue Patents are preceded by "Re."

Process of finishing cadmium plated goods. C. A. Ganser, 1,816,837, 3/14/30.

Process for refining ores or products containing aluminum oxide. T. R. Haglund, 1,816,842, 5/18/25; in Sweden 6/2/24.

Metal pickling process. G. L. Magoun, *et al.*, 1,816,860, 11/6/30.

Welding method and apparatus. T. E. Murray, 1,816,864, 5/29/29.

Chaplet. C. H. Reeder, 1,816,870, 6/3/29.

Electrolytic device. H. O. Siegmund, 1,816,875, 4/27/27 (with film-forming electrodes).

Process of cleaning wire. C. J. Warnke, 1,816,881, 3/10/30.

Annealing pot. C. A. Finn, 1,816,930, 7/8/30.

Self feeding swaging roll. E. W. Stoler, 1,816,940, 3/8/29.

Alloy and method of preparing same. (*Ag-Be.*) H. S. Cooper, 1,816,961, 12/2/25.

Manufacture and purification of magnesium. A. Jessup, 1,816,972, 4/2/26; in France 10/9/25.

Process of forging magnesium alloys. G. Michel, 1,816,983, 3/24/28; in France 3/31/27.

Process and machine for centrifugally extruding and casting substances. J. Merle, 1,817,012, 9/4/26.

Method and machine for rolling wheel disks. J. W. Hughes, 1,817,035, 11/20/26.

Converter smelting. H. H. Stout, *et al.*, 1,817,043, 4/8/27.

Treatment of zinciferous materials containing cadmium. H. M. Cyr, *et al.*, 1,817,068, 10/15/29.

Electric welding process. O. L. Mills, 1,817,092, 11/9/28.

Apparatus for galvanizing wire and the like. H. G. Black, 1,817,122, 4/22/29.

Method of open annealing sheet metal. A. T. Kahner, 1,817,152, 7/19/29.

Article and method of making the same. (*Zn coated.*) C. S. Brock, 1,817,174, 8/19/27.

Wheel welding machine. J. W. Hughes, 1,817,193, 1/30/28.

Pipe upsetting machine. J. H. Taylor, 1,817,215, 11/25/21.

Control means for hot blast stoves. F. H. Wilcox, *et al.*, 1,817,219, 8/13/27.

Welded rail joint construction. V. C. Armstrong, 1,817,225, 2/24/31.

Coating for metal casting molds and cores. M. L. Freed, 1,817,245, 5/10/30.

Extrusion of metal pipes and the like. P. Dunsheath, 1,817,301, 6/26/30; in Great Britain 7/1/29.

Method and means for the obtainment of decorative effects upon textile fabrics by brilliant metallic deposits. M. C. R. Hedde, 1,817,311, 1/24/30; in France 6/19/29.

Casting apparatus. T. B. Barr, 1,817,340, 8/3/29.

Process for case carburizing and heat treating metals. P. V. Brower, 1,817,345, 7/19/27; 1,817,407, 7/19/27.

Testing machine. (*Hardness testing.*) L. M. Showers, 1,817,170, 12/16/29.

Method and apparatus for casting journal boxes. L. W. Melcher, 1,817,388, 2/16/29.

Casting machine. L. C. Goad, *et al.*, 1,817,483, 10/12/29.

Treating metals and compositions therefor. J. C. Vignos, 1,817,500, 1/14/28.

Electrolytic separation of copper. M. Schlotter, 1,817,527, 9/28/29; in Germany 10/29/28.

Shake-out apparatus. V. J. Davis, 1,817,613, 2/17/28.

Die of the extruding and wire drawing type and process of making the same. J. T. Pratt, *et al.*, 1,817,680, 11/28/25.

Apparatus for producing low carbon iron. I. R. Valentine, 1,817,784, 11/-28/28.

Metallurgy of ores or materials containing tin. E. A. Ashcroft, 1,817,865, 5/7/28; in Great Britain 4/5/28.

Protective coating. (*Alborizing.*) R. E. Lowe, 1,817,888, 11/27/29.

Pyrometallurgical copper refining. H. H. Stout, 1,817,935, 8/15/28.

Manufacturing process. (*Tinning inside of Cu tubing.*) C. C. Ritter, *et al.*, 1,818,008, 11/27/29.

Magnetic material. (*Fe-Ni-Si.*) G. W. Elmen, 1,818,054, 1/12/27.

High frequency coil for electric induction furnaces. G. E. Taylor, 1,818,107, 7/5/28; in Great Britain 12/7/27.

Apparatus for the fusion electrolysis of metallic chlorides. R. Suchy, *et al.*, 1,818,173, 12/15/28; in Germany 12/23/27.

Partition for separating the products of fusion electrolysis of metallic chlorides. R. Suchy, *et al.*, 1,818,174, 2/11/30; in Germany 12/23/27.

Electroplating. L. R. Westbrook, 1,818,179, 2/23/28.

Method of coating substances. (*With alkali and alkaline-earth metals.*) H. S. Cooper, *et al.*, 1,818,196, 9/20/27.

Metal treating apparatus. C. Schumacher, 1,817,902, 1/16/30 (Original 3/3/27).

Electroplating. G. Lutz, *et al.*, 1,818,229, 2/23/28.

Ingot mold. T. McNally, 1,818,236, 3/18/27.

Electric furnace. W. E. Moore, 1,818,239, 9/25/29.

Device for annealing metal rings. F. Linnhoff, 1,818,341, 11/18/29; in Germany 11/24/28.

Process for the manufacture of metallic sheets. J. R. Cain, *et al.*, 1,818,379, 12/2/27.

Quenching oils. H. Rodman, 1,818,431, 5/16/29.

Method for the purification of iron and steel. M. Jaeger, *et al.*, 1,818,556, 12/13/28; in Germany 12/17/27.

Welding apparatus. J. A. Baker, 1,818,665, 5/23/27.

Molding apparatus. A. T. Bateman, *et al.*, 1,818,667, 7/30/28.

Furnace. J. F. Schrumn, 1,818,759, 5/8/30.

Zinc alloy. L. E. Wemple, *et al.*, 1,818,774, 1/21/31.

Electric furnace. H. G. Campbell, 1,818,789, 10/9/29; in Great Britain 5/15/29.

Electric furnace. A. Musso, 1,818,812, 3/14/28.

Method of recovering gold and silver. S. W. Giles, 1,818,846, 11/22/29.

Method of forming a compromise rail joint bar. D. L. Braine, 1,818,880, 6/5/29.

Process for preparing acid-proof cementing or lining compositions. K. Frank, *et al.*, 1,818,888, 9/8/26; in Germany 9/18/25.

Refractory article and composition for and method of making same. R. H. Martin, 1,818,903, 7/31/25.

Silicon carbide refractory article and method of making the same. R. H. Martin, 1,818,904, 4/18/25; this filed 7/22/27.

Process for precipitating rhodium, iridium, osmium, ruthenium, and the like. E. H. Reerink, 1,818,909, 5/14/28; in the Netherlands 10/20/27.

Soldering pot. R. E. Brown, 1,818,925, 12/2/29.

Mixer for welding torches. G. L. Hammon, 1,818,949, 4/6/29.

Method of producing substantially pure metallic magnesium directly by electrolysis of a fused bath. R. M. Hunter, 1,820,022, 5/31/29.

Furnace. C. L. Norton, 1,820,028, 2/8/29.

Electric welding machine. W. R. Hume, 1,820,139, 5/16/28; in Australia 5/21/27.

Process for the purification of metals. A. C. Jessup, 1,820,141, 10/23/28; in France 11/7/27.

Method of producing puddled iron ingots. A. H. Beale, 1,820,175, 7/19/28.

Method of granulating steel and forming wrought iron. A. H. Beale, *et al.*, 1,820,176, 7/19/28.

Manufacture of wrought iron from Bessemer steel. J. Aston, *et al.*, 1,820,177, 7/19/28.

Method of preparing and remelting synthetic slags. A. H. Beale, *et al.*, 1,820,178, 7/21/28.

Method of preparing or remelting wrought iron slag. E. L. Ives, 1,820,179, 7/21/28.

Forging machine. F. A. Halleck, 1,820,188, 7/30/20; this filed 9/9/24.

Furnace heat exchange apparatus. R. S. Riley, 1,820,199, 8/10/25.

Forging machine. W. H. Wineman, 1,820,207, 10/28/25.

Forging machine. W. H. Wineman, 1,820,208, 1/4/28.

Optical pyrometer. D. C. Gall, 1,820,219, 6/23/28; in Great Britain 6/-29/27.

Molding machine. H. B. Swan, 1,820,405, 11/16/29.

Treatment of zinc-bearing material. W. C. Hooey, 1,820,455, 2/7/29.

Fissure detector for metals. E. A. Sperry, 1,820,505, 8/10/28.

Apparatus for cooling and annealing metal bars. J. R. George, Re 18,152 (original 1,642,437, 9/13/27), 2/19/31.

Front wall for open hearth furnaces. H. Rateau, *et al.*, 1,819,001, 1/16/31.

Air and water cooled furnace and generator block. G. W. Davey, 1,819,016, 12/29/25.

Valve aggregate for regenerative furnaces, heat apparatus, etc. E. S. S. Wohlfahrt, 1,819,052, 10/30/29; in Sweden 9/19/29.

Operation of blast furnaces. E. Baumgartner, 1,819,064, 2/7/30; in Germany 2/11/29.

Electroplating and electroplating apparatus. J. A. Smith, 1,819,130, 4/19/26.

Method of producing pyrophoric iron. H. L. Hartenstein, 1,819,164, 10/-18/26.

Electric process of reducing ores. A. E. Greene, 1,819,238, 7/17/24.

Electric smelting apparatus. A. E. Greene, 1,819,239, 6/1/25.

Art of extruding cold materials. (*Metals.*) J. G. C. Mantle, 1,819,254, 3/31/24.

Mandrel for tube rolling mills. P. Multhaupt, 1,819,257, 8/10/29; in Germany 11/26/28.

Bearing. (*Welded-on porous lining.*) C. R. Short, 1,819,272, 9/22/27.

Method of assembling structural steel. (*By welding.*) A. A. Goerz, 1,819,287, 12/1/28.

Method of annealing sheet copper. G. A. Hempstead, 1,819,291, 1/30/30.

Hot top. L. G. Firth, *et al.*, 1,819,364, 9/24/29.

Mold. L. G. Firth, 1,819,365, 11/2/29.

Tube swaging machine and method. F. Müller, 1,819,376, 8/25/24.

Apparatus for roasting ores. H. H. Nicholson, 1,819,436, 7/30/29.

Method of making silicon iron compounds. J. A. Parsons, 1,819,479, 1/23/30.

Counterflow carburizing machine. H. H. Harris, 1,819,509, 3/15/29.

Resistor and terminal connection. A. J. Hanson, 1,819,554, 11/9/27.

Electroplating apparatus. J. W. Hughes, 1,819,603, 9/21/28.

Method of treating waste alloys for the purpose of removing therefrom certain constituents whose presence renders the alloys unsuitable for certain uses. P. Kemp, 1,819,607, 6/23/28; in Austria 6/23/27.

Ring forming machine with knockout. C. L. Wiles, 1,819,630, 2/2/28.

Shearing metal plates. J. J. Cain, 1,819,636, 4/6/28.

Electric soldering iron. J. Buccola, 1,819,671, 5/16/30.

Ingot mold. E. Gathmann, 1,819,705, 2/5/31.

Process for composite casting. I. Sugimura, *et al.*, 1,819,722, 11/22/29.

Continuous sheet metal. W. M. Blecker, 1,819,763, 6/23/28.

Continuous strip metal. W. M. Blecker, 1,819,764, 6/23/28.

Chill for castings. G. C. Bumbaugh, 1,819,765, 5/4/28.

Process for decomposing ores of the rare earths, of zirconium and titanium, in a cycle by means of sulphuric acid. J. D'Ans, 1,819,770, 5/12/28; in Germany 5/23/27.

Process of applying heat. W. A. Darrah, 1,819,772, 10/12/29.

Method of casting continuous polygonal bands. W. M. Carty, 1,819,942, 2/20/29.

Method for manufacturing ingots. Z. Colwell, 1,820,597, 3/7/30.

Manipulator for rolling mills. A. T. Keller, 1,820,622, 2/8/30.

Electrode for electric furnaces. P. L. J. Miguet, 1,820,625, 6/23/28; in France 3/31/28.

Means and method of forming and feeding weldrods. H. J. Burnish, 1,820,649, 5/8/30.

Process of obtaining beryllium compounds from beryllium-bearing minerals. H. Fischer, 1,820,655, 12/13/28; in Germany 12/15/27.

Foundry tool. A. A. Meyer, 1,820,819, 4/25/29.

Apparatus for obtaining light metals by electrolysis. E. Steinbuch, *et al.*, 1,820,844, 10/14/29; in Switzerland 8/23/29.

Apparatus for the dipping of tubes or rods for pickling, etc. H. Trevorrow, 1,820,851, 4/29/29; in Great Birtain 5/10/28.

Heat treating furnace. H. O. Breaker, 1,820,879, 3/3/28.

Manufacture of potassium. W. Busch, *et al.*, 1,818,881, 7/21/28; in Germany 8/5/27.

Method of reforming bars. G. Langford, Re 18,165 (original 1,712,506, 7/16/26), 7/6/31.

Austrian Patents

Subject of Invention, Patentee, Patent No. and Date of Beginning of Term of Patent.

Process for producing high-strength cast iron. Meier & Weichelt, 123,363, 2/15/31.

Process for bright-annealing metals. Siemens-Schuckertwerke G. m. b. H., 123,238, 12/15/29.

Process for deoxidizing ingot iron. The Armco International Corp., 123,364, 2/15/31.

Process for making ingot iron which is particularly suitable for enameling. Same patentee, 123,368, 2/15/31.

Process for making steel by carburizing pure molten iron. H. J. van Royen, 123,369, 2/15/31.

Process for refining iron and steel baths. I. G. Farbenindustrie Akt.-Ges., 123,376, 2/15/31.

Lead-base bearing metal containing alkali and alkaline-earth metals, magnesium and aluminum, and process for making the same. W. Mathesius, *et al.*, 123,366, 2/15/31.

Process for making alloys containing aluminum and silicon but practically no titanium and iron, out of titanium- and iron-bearing raw materials containing alumina and silica. Metallges. Akt.-Ges., 123,388, 2/15/31.

Refractory block for supporting heating wires. Siemens-Schuckertwerke G. m. b. H., 123,367, 2/15/31.

Device for connecting quadrangular carbon electrodes, particularly those of electric furnaces. Siemens Planiawerke Akt.-Ges. für Kohlefabrikate, 123,387, 2/15/31.

Process for butt-welding two-piece hollow bodies. Budd-Wheel Co., 123,359, 2/15/31.

Mechanical extrusion press for making metal pipes. Testa G. m. b. H., 123,-654, 5/15/29.

Device for automatically disconnecting the drive of pulling drums of wire-drawing benches. C. Rasch, 123,769, 3/15/31.

Wire coiling device. O. Stern, *et al.*, 123,780, 3/15/31.

Process for making solid or hollow ingots by centrifugal casting. Mannesmannröhren-Werke, 123,839, 3/15/31.

Apparatus for examining crystalline bodies with the aid of X-rays. N. V. Philips' Gloeilampenfabrieken, 124,017, 3/15/31.

Checkerwork for the regenerators of melting furnaces and the like. "Feuerungstechnik" Spezialbauunternehmung G. m. b. H., 123,855, 3/15/31.

Trough-shaped tilting vessel for pouring molten metal, particularly iron. K. Rein, 123,886, 3/15/31.

Motor piston made of aluminum containing over 20% silicon. K. Schmidt G. m. b. H., 123,888, 3/15/31.

Casting machine actuated by pressure of a piston. J. Polák, 123,899, 3/15/31.

Centrifugal casting process and mold for making thin annular castings. W. Bremicker, 123,900, 3/15/31.

Process for making aluminum and aluminum alloys out of pre-alloys. T. R. Haglund, 123,814, 3/15/31.

Process for removing suspended particles of iron and similar impurities from magnesium and high-percentage magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 123,808, 3/15/31.

Process for increasing the corrosion-resistance of hot-worked objects made of magnesium containing 0.5–2.5% manganese. Same patentee, 123,818, 3/15/31.

Process for making shaped objects. F. Krupp Akt.-Ges., 124,079, 11/15/30.

High-frequency induction furnace. Oesterreichische Siemens-Schuckertwerke, 123,843 (Addition to 119,737), 3/15/31.

Process for making non-passive nickel electrodes. The International Nickel Co., Inc., 123,835, 3/15/31.

Process for coating metal conductors (preferably strip or wire) with a hydroxide-oxide mixture, the metal of which is different from the conductor metal. F. Hansgirg, 124,070, 4/15/30.

Welding flux containing potassium and lithium, for welding magnesium and its alloys. I. G. Farbenindustrie Akt.-Ges., 123,796, 3/15/31.

Process for cleaning metal surfaces. J. H. Gravell, 123,803, 3/15/31.

Process for metallizing objects of organic origin in a high vacuum. K. Richter, 123,816, 3/15/31.

Process for making sulphonation productions for use as inhibitors in metal-pickling baths, especially those for iron and steel. V. Bertleff, 123,823, 3/15/31.

Process for protecting metallic coatings on iron and steel during the plating process. Copperized Steel, Ltd., 123,824, 3/15/31.

Process and apparatus for the continuous surface- and heat-treatment of metals in the form of strip. Same patentee, 123,825, 3/15/31.

Process for making a lead solder. American Machine & Foundry Co., 123,827, 3/15/31.

Process and solder for soldering tungsten and molybdenum. N. V. Philips' Gloeilampenfabrieken, 123,828, 3/15/31.

Process and material for soldering and welding chains, rings, jewelry and the like. J. Brunhübner, 123,829, 3/15/31.

Process for making pickling baths for iron and steel, containing water-soluble sulphonation products. V. Bertleff, 123,832, 3/15/31.

Process for making a stable foam, particularly on acid pickling baths. J. H. Gravell, 123,833, 3/15/31.

Device particularly for guiding the burners of cutting or welding machines by a template. A. Schmidt, 123,766, 3/15/31.

Process and apparatus for welding two-piece hollow bodies. Budd Wheel Co., 123,776, 3/15/31.

Process for making polygonal containers, particularly out of rustless steel, especially for ice cells and the like. F. Krupp Akt.-Ges., 123,785, 3/15/31.

Process for plating metals with aluminum or aluminum alloys. Vereinigte Silberhammerwerke Ketze & Co., 123,770, 3/15/31.

British Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Note: When the date applied for differs from the date on which the application was lodged at the British Patent Office, the former date is given, followed by *.

Detection of cracks in iron or steel parts by magnetic means. W. L. Lorkin, *et al.*, 351,767, 7/16/30.

Process for manufacturing steel rims and hoops used in wheels and hubs. A. Dechenne, 351,779, 8/11/30.

Gold alloy particularly suitable for jewelry. Cartier, 351,811, 7/14/30*.

Salt bath furnaces for the heat treatment of steel and other metals. Siemens-Schuckertwerke Akt.-Ges., 351,812, 9/19/29*.

Method for the manufacture of tube welding bells. J. Mark, 351,840, 9/24/30.

Heat recuperating structures. H. De Gaillard et Cie., 351,863, 10/17/29*.

Regulation of electric arc soldering machines. British Thomson-Houston Co., Ltd., 351,883, 11/16/29*.

Oxy-arc cutting tools. Same patentee, 351,895, 1/9/30*.

Joining zinc-aluminum alloys to steel. H. C. Hall, 351,977, 1/25/30.

Reducing zinciferous materials containing lead and other contaminating metals. The New Jersey Zinc Co., 352,005, 2/3/30; 353,371, 12/30/29.*

Metal rolling. J. B. Tytus, 352,047, 3/21/30.

Magnetic materials. Electric Research Products, Inc., 352,019, 4/2/29.*

Annealing pots and the like. E. L. James, 352,061, 4/2/30.

Control of electric generators for arc welding. J. H. Holmes & Co., Ltd., 352,-066, 4/4/30.

Welding electrodes and coatings therefor. Hollup Corp., 352,086, 4/5/30.

Cathodes for the electrolytic refining of metals. United States Metals Refining Co., 352,104, 4/9/30.

Heat treatment furnaces. Hevi Duty Electric Co., 352,174, 5/22/29.*

Refining aluminum, magnesium and their alloys. H. C. Hall, 352,199, 6/5/30.

Rust proofing of iron, steel and other metals. W. H. Cole, 352,202, 6/10/30.

Method of electric welding. R. D. Malm, 352,223, 6/24/30.

High-strength grey cast irons, and methods of producing same. International Nickel Co., Inc., 352,510, 1/5/29.*

Process for the manufacture of copper wire. S. O. Cowper-Coles, 352,385, 1/7/30.

Electrically driven roller-way conveyers. F. Krupp Grusonwerk A.-G., 352,-402, 5/29/29.*

Means for preheating the air supply to furnaces. H. A. S. Gothard, *et al.*, 352,405, 4/4/30.

Process of and apparatus for the manufacture of hollow bodies, especially tubes, by drawing over a mandrel. Metallges. A.-G., *et al.*, 352,505, 4/10/30.

Electric upsetting and forging machines. G. Benedetto, 352,508, 4/10/30.

Manufacture of material suitable for resisting rifle bullets and other projectiles, and for other purposes. R. A. Hadfield, 352,548, 4/12/30.

Presses for working sheet metal and the like. Marquette Tool & Mfg. Co., 352,559, 4/16/30.

Method of reducing ores with gases. F. M. Wiberg, 352,580, 7/6/30.*

Expanded-metal and other sheets, and processes for manufacturing such sheets. M. Kaminetsky, 352,584, 4/23/30.

Processes and apparatus for the cooling of annealed goods in cooled vessels. H. Prüfert, 352,586, 4/24/30.

Pressure die-casting machine. Armstrong, Whitworth & Co., Ltd., *et al.*, 352,600, 5/1/30.

Process for the manufacture of hollow profile sections from sheet metal. M. Gessner, 352,614, 5/6/30.

Copper-silicon-zinc alloys. Hirsch, Kupfer-und Messingwerke A.-G., 352,639, 2/13/30*.

Method for the production of oxidic coatings on articles made from aluminum and its alloys. R. E. Muller, 352,656, 5/24/29*.

Process of purifying or refining non-ferrous metals and alloys. D. R. Tullis, *et al.*, 352,671, 6/4/30.

Method of annealing or other heat-treatment of metals, more especially iron and steel. N. G. Elfstrom, 352,677, 6/10/30.

Sheaths of electric cables and pipes of lead and lead alloys. Callender's Cable & Construction Co., Ltd., *et al.*, 352,700, 6/21/30.

Method for welding steel parts. L. C. Delachaux, 352,714, 7/27/29*.

Apparatus for autogenous cutting and welding under water. H. Topper, 352,-749, 7/30/29*.

Metal alloys. C. Vangrevenynge, et *al.*, 352,759, 1/7/30*.

Manufacture of seamless lead pipes, in particular cable sheaths. Siemens-Schuckertwerke A.-G., 352,797, 12/3/29*.

Steel mold and the method of manufacturing the same. United States Pipe & Foundry Co., 352,824, 2/4/30*.

Agglomeration of finely divided ferruginous ores, concentrates, and the like. A. Folliet, *et al.*, 352,832, 10/30/29*.

Manufacture of tubes. Vereinigte Stahlwerke A.-G., 352,868, 2/8/30*.

Method of bundling rod-shaped material, particularly metal rods or tubes. Hirsch, Kupfer-und Messingwerke A.-G., 352,875, 11/27/29*.

Manufacture of refractory products from magnesium silicates. Metallges. A.-G., *et al.*, 352,881, 7/7/30*.

Metal-rolling mills. F. Möller, 352,889, 1/2/30*.

Electrical welding-machines. Vereinigte Stahlwerke A.-G., 352,895, 2/7/30*.

Iron-titanium alloys. W. Kroll, 352,964, 2/16/29*.

Method of and apparatus for shaping metal from a hollow blank. Bridgeport Brass Co., 353,040, 3/18/30.

Cobalt high-speed tool steel. Oesterreichische Schmidt-Stahlwerke A.-G., 352,951, 4/14/30.

Method of operating furnaces for brazing, annealing and the like. British Thomson-Houston Co., Ltd., 353,062, 4/19/29*.

Manufacture of sponge iron. I. Rennerfelt, *et al.*, 353,180, 6/12/30.

Method and apparatus for casting copper or equivalent copper alloys. American Metal Co., Ltd., *et al.*, 353,205, 6/24/30.

Process of treating metallurgical slimes. Metallges. A.-G., 353,212, 6/28/29*.

Metal strip or sheet rolling processes and apparatus. Morgan Construction Co., 353,224, 7/4/30.

Fin tubing for heat-exchange apparatus and method of making the same. Griscom-Russell Co., 353,251, 8/1/29*.

Manufacture of welded articles. H. Schmuckler, 353,254, 5/21/30.

Electric induction furnaces. Associated Electrical Industries, Ltd., 353,270, 8/14/29*.

Cooling-boxes for metallurgical furnaces. J. H. Ledeboer, 353,298, 8/29/30.

Drawing and winding drum for multiple-pass wire-drawing machines. W. Nacken, 353,326, 10/3/30.

Devices for suspending articles in electric-plating baths. Langbein-Pfanhauser-Werke A.-G., 353,332, 11/30/29*.

Receiving-apparatus for goods in bulk to be galvanically coated. Siemens & Halske A.-G., 353,337, 10/18/29*.

Methods of reclaiming and reusing metallic-scrap mixtures. Ford Motor Co., Ltd., 353,377, 2/4/30*.

Iron, chromium, and nickel alloys. International Nickel Co., 353,448, 1/22/29*, and 353,459, 1/22/29*.

Armour-piercing projectiles. R. A. Hadfield, *et al.*, 353,425, 1/22/30.

Method of producing ferro-chrome. K. M. Simpson, 353,406, 10/9/29*.

Method of cleaning the surface of metals. Bullard Co., 353,488, 3/21/30.

Preventing corrosion of metallic surfaces. H. Sutton, *et al.*, 353,415, 4/14/30.

Metal castings. E. A. Hailwood, 353,497, 4/22/30.

Method of producing covered weld-rods for electric arc welding, and weld-rods produced thereby. A. F. Burgess, 353,499, 4/22/30.

Device for casting bearings. R. Fuche, 353,530, 4/30/30.

Foundry molding-machine. A. Baillot, 353,545, 3/4/30*.

Apparatus for measuring the hardness of materials. A. F. Shore, 353,549, 5/5/30.

Welding. I. G. Farbenindustrie A.-G., 353,671, 7/12/30.

System of construction of suspended furnace roofs. E. Strunk, *et al.*, 353,682, 7/17/30.

Machines for testing the hardness of materials. W. & T. Avery, Ltd., *et al.*, 353,729, 8/21/30.

Methods of and machines for producing core boxes. A.-G. der Eisen & Stahlwerke vorm. G. Fischer of Schaffhausen, 353,734, 8/23/30.

Apparatus for testing steel-wire ropes. Smith, Major, & Stevens, Ltd., *et al.*, 353,743, 9/1/30.

Soldering-materials. General Electric Co., Ltd., 353,758, 9/28/29*.

Apparatus for sorting rods, tubes, or the like. British Thomson-Houston Co., Ltd., 353,785, 10/9/29*.

Boxes for packing tin-plates and for the like purposes. W. H. Bolt, 353,807, 11/20/30.

Production of metallic tungsten. I. G. Farbenindustrie A.-G., 353,815, 12/31/29*.

Production of metal stampings. Pressed Steel Co. of Great Britain, Ltd., *et al.*, 353,820, 12/23/30.

Manufacture of fusion-welded pipe. Air Reduction Co., Inc., 353,821, 1/8/30*.

Method and apparatus for machining rolls for rolling-mills and the like. Mannesmannröhren-Werke, 353,829, 2/15/30*.

Tube draw benches. Demag A.-G., 353,830, 2/20/30*.

Sintering-plants. H. Eriksson, 353,833, 3/27/30*.

Rolling metal. Cold Metal Process Co., 353,525, 1/11/30*.

Process for manufacturing aluminum alloys. S. Junghans, 353,891, 1/31/29*.

Two-step sulphatizing roasting process. F. A. Brinker, 353,861, 2/18/30.

Melting flux for purifying aluminum, its alloys, and other non-ferrous metals. F. Dubberley, *et al.*, 353,867, 3/26/30.

Protective masks for the use of welders. H. C. Greene, *et al.*, 354,019, 7/1/30.

Hard metal compositions. British Thomson-Houston Co., Ltd., 354,028, 7/16/29*.

Presses for drawing sheet metal and the like. F. J. Rode, 354,045, 7/29/30*.

Conversion of metallic ores. H. Edwards, *et al.*, 354,098, 9/13/30.

Manufacture of tools. F. Krupp A.-G., 354,112, 4/16/30*.

Alloys of palladium, silver, and copper. International Nickel Co., Inc., 354,216, 1/28/29*.

Electric furnaces. Carborundum Co., 354,172, 3/3/30.

Steel capable of resisting rust and corrosion. R. Kesselring, *et al.*, 354,177, 3/30/29*.

Sheet-feeding devices. E. G. Budd Mfg. Co., 354,223, 4/3/29*.

Method and means for lapping wire-drawing and other dies. W. Haddow, 354,225, 4/5/30.

Apparatus for forging and roughing-out iron and steel bars by electricity. Soc. Holding des Brevets et Procédés Giacchino pour l'Ebauchage Electrique, 354,188, 4/30/29*.

Machines for the pressure casting of metals. Armstrong, Whitworth & Co., *et al.*, 354,227, 5/1/30.

Feed rods for use in soldering, brazing, or welding. A. Stephenson, *et al.*, 354,195, 5/1/30.

Aluminium-copper-light metal alloys. O. Kamps, 354,202, 5/2/30.

Rolling-mills. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 354,234, 5/5/30.

Welding wire. G. Bammer, 354,261, 5/6/30.

Lead extrusion-presses. B. E. Marean, 354,365, 5/8/30.

Manufacture of chromium or alloys thereof. General Electric Co., Ltd., *et al.*, 354,387, 5/10/30.

Manufacture of tubes and the like. Brittania Tube Co., Ltd., *et al.*, 354,457, 8/2/30.

Moulds for producing hollow metal bodies by vertical centrifugal casting. H. Lent, *et al.*, 354,459, 8/5/30.

Manufacture and production of shaped articles from metal powders. I. G. Farbenindustrie Akt.-Ges., 354,562, 8/21/30.

Oxy-acetylene and like torches for welding or like purposes. Air Reduction Co., Inc., 354,599, 10/5/29*.

Manufacture of metal cutting and working and like tools. F. Krupp Akt.-Ges., 354,641, 11/21/29*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date

Electric furnace. P. L. J. Miguet, *et al.*, 313,347, 8/8/30.

Production of zinc. C. F. von Girsewald, *et al.*, 313,348, 11/7/28.

Lead refining method. P. W. Davis, 313,365, 4/22/30.

Method of producing zinc salt solutions. W. Kartenbeck, 313,388, 12/22/28.

Method of hardening internal surfaces. The American Manganese Steel Co., 313,429, 5/13/29.

Method of making copper weld tubing. The Bundy Tubing Co., 313,454, 10/18/29.

Acid inhibitor. The E. I. duPont de Nemours & Co., 313,474, 11/4/29.

Metallic paint. The Flintkote Co., 313,483, 4/24/30.

Method of roasting fine ores. The General Chemical Co., 313,486, 1/3/29.

Aluminum alloy. Metallges. Akt.-Ges., 313,506, 12/4/29.

Annealing apparatus. N. V. Mij. tot Beheer en Exploitatie van Octrooien, 313,509, 9/11/29.

Galvanizing or electroplating process. La Waldberg S. A., 313,558, 12/6/29.

Molding apparatus. V. J. Davis, 313,617 & 313,618, 6/7/29.

Method of recovering nickel from ores. F. L. Duffield, 313,621, 2/1/30.

Apparatus for converting molten metals into solid fabricated articles. H. Harris, 313,630, 1/29/31.

Process of treating pyrites. S. I. Levy, 313,647, 9/17/28.

Apparatus for treating molten slag. M. O. Sem, 313,685, 2/26/30.

Heat-resisting liquid metal for mending various metallic articles. M. Taradash, 313,693, 11/26/30.

Process for recovering cadmium from its compounds. The American Lurgi Corp., 313,712, 9/17/30.

Process of roasting and sintering pulverulent ores. The American Lurgi Corp., 313,713, 9/20/30.

Method of making brake drums. The Budd Wheel Co., 313,724, 1/20/30.

Electric heating furnace. The Geo. J. Hagan Co., 313,787, 10/30/30.

Constructional steel. F. Krupp Akt.-Ges., 313,797, 9/4/29.

Muffle furnace. F. Krupp Akt.-Ges., 313,798, 8/28/30.

Steel swage. (Nitrided.) The Nitralloy Ltd., 313,813, 2/20/29.

Apparatus for treating zinc. The St. Joseph Lead Co., 313,824, 12/9/29.

Process of treating sulphide ores. The Sulphide Corp., 313,826, 5/8/30.

Tubing die. The Titeflex Metal Hose Co., 313,832, 5/20/29.

Method of treating aluminum oxide minerals. L. M. Hughes, 313,855, 7/11/30.

Method of treating aluminum oxide. L. M. Hughes, 313,856, 7/11/30.

Finishing roll polisher. D. H. Williams, *et al.*, 313,865, 10/16/29.

Manufacture of metal billets or bars. F. W. Harbord, *et al.*, 313,873, 10/30/29.

Device for cutting holes. (Autogenous.) H. Greggersen, 313,903, 6/5/29.

Manufacture of magnesium and the alkaline earth metals by electrolysis. A. C. Jessup, 313,909, 7/5/26.

Method of metallizing articles of organic origin. K. Richter, 313,933, 8/1/30.

Method of thinly coating articles. K. Richter, 313,934, 8/1/30.

Electric furnace. A. Stansfield, 313,941, 1/3/30.

Non-corrosive alloy. The American Machine & Foundry Co., 313,951, 6/19/28.

Machine for bending metal sheets. The Cairns Development Corp., 313,931, 11/2/29.

Production of refractory articles. (Tungsten powder sintered to wool.) The Canadian Westinghouse Co., Ltd., 313,971, 12/15/23.

Method of producing uranium and uranium-zinc alloys. Same patentee, 313,973, 7/2/29.

Wire-bending die. Same patentee, 313,974, 3/26/30.

Lined bearing. The Cleveland Graphite Bronze Co., 313,981, 10/24/28.

Method of roasting finely divided sulphide ores. The General Chemical Co., 314,002, 1/3/29.

Apparatus for treating flux-core solder. The Kester Solder Co., 314,026, 10/13/30.

Apparatus for purifying zinc ores. The Matthiessen & Hegeler Zinc Co., 314,028, 5/17/30.

Welding method. The National Tube Co., 314,032, 10/6/30.

Apparatus for cooling wires in annealing furnaces. The Niagara Weaving Co., Ltd., 314,033, 7/5/30.

Method of preparing surfaces for coating. The Parker Rust-Proof Co., 314,035, 9/3/29.

Coated zinc product. Same patentee, 314,036, 9/30/29.

Method of making metallic magnesium. The Dow Chemical Co., 314,086, 5/4/25.

Danish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process and apparatus for welding two hollow pieces together. Budd Wheel Co., 44,206, 1/10/30.

Process and machine for rolling bulges and grooves. Vereinigte Stahlwerke Akt.-Ges., 44,222, 2/15/30.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Method of operating furnaces for melting ores, minerals and metals. Soc. Oxythermique, 708,581, 12/30/30.

Improved process for recovering and reutilizing mixtures of metal scrap. Ford Motor Co., Ltd., 709,107, 1/9/31.

Process for obtaining metals in pulverulent form. Vitriolfabrik Johannisthal Akt.-Ges., 709,124, 1/10/31.

Improvements to hard metal compositions and to processes for making them. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, Additions 38,878 & 38,897 (6th & 7th additions to 654,210 filed 4/4/28). 7/3/30 & 7/25/30.

Process and apparatus for making fusion-welded pipe. Air Reduction Co., 709,049, 1/6/31.

Permanent molds for casting metals, and processes for making them. J. B. Durand, 709,096, 1/9/31.

Improvements to electrodes for welding apparatus and machines. Ford Motor Co., Ltd., 709,106, 1/9/31.

Process for the electrolytic separation of copper. Asociaion de Productores de Yodo de Chile, 708,989, 10/1/29.

Process for the electrolytic separation of gold and silver. Same patentee, 708,990, 11/3/29.

Annealing furnace cooling chamber, containing a reducing atmosphere. H. Schaeffer, 709,247, 1/13/31.

Mining tool with hard-metal tip. Gewerkschaft Wallram, Addition 38,958 (1st addition to 696,198 filed 5/28/30), 8/27/30.

Improvements to processes for making nickel carbonyl. The Mond Nickel Co., Ltd., 709,381, 1/15/31.

Improvements to processes and apparatus for the electrolytic production of light metals. Soc. d'Electrochimie, d'Electrométallurgie et des Aciéries d'Ugine, 709,476, 4/18/30.

Method of equalizing the pressure in the grooves in the rolls of pilger mills. Vereinigte Stahlwerke Akt.-Ges., 709,616, 1/19/31.

Pack-annealing furnace with screw conveyor. H. Lindhorst, Addition 38,964 (1st addition to 680,924 filed 8/28/29), 8/29/30.

Improvements in the heat treatment of ferrous metals. A. P. & G. Mahoux, Addition 38,999 (1st addition to 700,049 filed 11/18/29), 2/27/30.

Process and mill for rolling sheet metal. J. R. Spear, *et al.*, 709,326, 11/28/30.

Process and apparatus for cleaning metal objects. W. Frey & Co., 709,338, 12/31/30.

Improvements to arc welding apparatus. J. E. J. Languepin, 709,346, 1/8/31.
Process for making bearings by centrifugal casting. Th. Goldschmidt Akt.-Ges., 709,349, 1/9/31.
Improvements in the manufacture of finished and semi-finished steel objects. Timken Holding & Development Co., 709,359, 1/14/31.
Rolling mill. F. Krupp Grusonwerk Akt.-Ges., 709,382, 1/15/31.
Means for rolling up spools or coils of wire or the like in the drawing of wire and the like. Morgan Construction Co., 709,384, 1/15/31.
Press for drawing hollow objects. F. Krupp Akt.-Ges., 709,359, 1/16/31.
Induction furnace. H. Zepernick, 709,580, 1/17/31.
Method and means for operating several arc furnaces in parallel, using rectifiers and a common transformer. Akt.-Ges. Brown, Boveri & Cie., 709,673, 1/20/31.
Salt bath furnace. Siemens-Schuckertwerke Akt.-Ges., Addition 38,953 (1st addition to 699,179 filed 7/21/30), 8/22/30.
Process for making articles which are to be machined with chip-removing tools. Sachsische Gussstahlwerke Dohlen Akt.-Ges., 709,828, 1/16/31.
Alloys of copper, tin, silver and nickel. R. Ozlberger, 709,850, 1/22/31.
Mechanism for polishing rolls of hot-rolling mills. Continental Can Co., Inc., 710,014, 1/27/31.
Process and apparatus for the direct conversion of molten metals or molten alloys into solid products. H. Harris, 710,099, 1/28/31.
Improvements to foundry molding machines. British Insulated Cables, Ltd., 709,786, 9/24/29.
Tube. Bundy Tubing Co., 709,911, 1/24/31.
Improvements in the heat treatment of metal objects, particularly rails. Bethlehem Steel Co., 709,949, 1/26/31.
Machine for electrically welding wires or an ensemble of wire. Vereinigte Stahlwerke Akt.-Ges., 709,994, 1/27/31.
Process and product for protecting aluminum, magnesium, zinc, and their alloys against corrosion. Soc. Continentale Parker, 710,042, 4/24/30.
Process for pressing rods and wire. Hirsch, Kupfer- und Messingwerke Akt.-Ges., 710,076, 1/28/31.
Pressure tanks for apparatus for cleaning castings with a mixture of sand and water. Badische Maschinenfabrik, 710,082, 1/28/31.
Improvements to processes and machines for arc welding. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 709,795, 12/12/30.
Method of utilizing the heat of melting furnaces. Vereinigte Stahlwerke Akt.-Ges., 709,975, 1/26/31.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for making metal handles covered with a heat resistant composition by compound casting. Aluminium Walzwerke Wutöschingen G. m. b. H., 529,351, 3/2/29.
Roasting furnace for the continuous roasting of sulfide ores. I. G. Farbenindustrie Akt.-Ges., 529,700, 6/23/27.
Process for reducing crude ores containing zinc, lead and similar volatilizable metals. F. L. Duffield, 529,431, 11/15/28; Great Britain 8/4/28.
Process for preventing deep corrosion of base metals. I. G. Farbenindustrie Akt.-Ges., 529,606, 10/11/27.
Process for making pipe coils of any desired section out of metal strip. D. Smith, Ltd., & D. Smith, 529,753, 6/21/29.
Copying device, particularly for torch cutting machines. C. Krebs, 529,677, 1/26/29.
Reversible drive, particularly for reversing rolling mills. J. M. Voith, 529,872, 12/10/29.
Return guide trough for roll trains. Vereinigte Oberschlesische Hüttenwerke Akt.-Ges., 530,040, 5/22/30.
Wire-drawing machine. Vereinigte Deutsche Metallwerke Akt.-Ges., 530,-275, 12/1/27.
Device for loading lead into vertical lead-pipe or cable presses. Hydraulik G. m. b. H., 529,873, 3/7/29.
Process for making finned tubing. M. Schlötter, 529,964, 8/30/29.
Process for making sponge chrome-iron and sponge chromium. H. G. Flodin, 530,030, 3/29/28; Sweden 11/17/27.
Nipple for use in carrying and for screwing together the sections of electrodes for electric furnaces. Siemens-Planiawerke Akt.-Ges. für Kohlefabrikate, 529,837, 12/25/29.
Controllable welding limit device. Siemens-Schuckertwerke Akt.-Ges., 530,061, 5/21/26.
Transformer, particularly for arc welding. Allgemeine Elektricitäts Ges., 530,062, 6/30/29.
Welding compass for welding non-circular objects. Siemens-Schuckertwerke Akt.-Ges., 530,063, 6/5/27.
Channel stone made of separately produced core pipe and sheath. W. Studte, 529,899, 3/8/30.
Process for making compound castings, particularly rolls. Vereinigte Stahlwerke Akt.-Ges., 529,838, 5/14/30.
Removing iron from copper salt solutions containing ferrous salts. I. G Farbenindustrie Akt.-Ges., 529,903, 11/13/29.
Process for forming electrolytic deposits of metals of the platinum group. Baker & Co., Inc., 529,848, 5/16/30; U. S. 7/2/29.
Finder and lifter for articles dropped into electrolytic baths. A. Jensch, 530,017, 11/19/30.
Process for forming metallic deposits. I. G. Farbenindustrie Akt.-Ges., 529,849, 6/28/28.
Process for making metal surfaces particularly those of aluminum and magnesium, resistant to high temperatures. The Expanded Metal Co., Ltd., 530,018, 3/3/27; Great Britain 3/17/26.
Burner for autogenous cutting under water. H. Töpper, 530,465, 7/31/29.
Device for separating or opening thin sheets rolled in packs. J. Doubs, 530,357, 2/28/29.
Tube-rolling mill for making small tubing. Mannesmannröhren-Werke, 530,368 (Addition to 440,654), 8/21/27.
Roll, particularly for the hot-rolling of metals. Siemens-Schuckertwerke Akt.-Ges., 530,484, 7/28/27.
Wire reel. H. Böcher, 530,466, 11/19/29.
Horizontal extrusion press. F. Krupp Grusonwerk Akt.-Ges., 530,467, 3/25/28.
Method of making a welded pipe connection, with welded seam relieved from stress. F. Heck, 530,561 (Addition to 501,377), 6/15/27.
Process for reducing iron ores with gases. I. G. Farbenindustrie Akt.-Ges., 530,568 (Addition to 528,347), 7/2/25.
Process for producing sponge iron from iron ores. F. Krupp Akt.-Ges. Fried. Alfred Hütte, 530,569 (Addition to 529,136), 9/21/29.
Guide elements for foundry molds. E. Borner, 530,510, 9/18/30.
Process for working up sulphidic iron ores containing copper and lead, and optionally zinc and other metals. Verein für chemische u. metallurgische Produktion, 530,516 (Addition to 526,610), 2/6/29.
Process for the electrolytic separation of gold. H. Paweck, *et al.*, 530,525 11/7/29, Austria 7/13/28.
Apparatus for making objects by the electrolytic deposition of metal on a form. G. Rosenqvist, 530,605, 10/25/29.
Process for making draw plates for drawing wires. Electrical Research Products, Inc., 530,778, 4/4/29; U. S. 4/12/28.
Process for making double-walled vessels. Ges. für Linde's Eismaschinen Akt.-Ges., 530,779, 10/9/28.
Head for slot burners for the surface hardening of objects. C. V. Haryes, 530,884, 9/13/30.
Process for extruding long objects, such as pipe or bars. F. Singer, 531,294, 1/13/25; U. S. 10/11/24.
Throat closure. Kölsch-Fölzer-Werke Akt.-Ges., *et al.*, 531,160, 11/19/29.
Hearth furnace burner using gaseous fuels. Witkowitzer Bergbau u. Eisenhütten-Gewerkschaft, *et al.*, 531,206, 12/21/24.
Process for the bright-annealing of iron and steel objects in thin sheet iron covers, and covers for working the process. Siemens-Schuckertwerke Akt.-Ges., 530,865, 4/1/26.
Electric soldering device, in which the element used for soldering is connected to the secondary of a stationary transformer. Elektrische Löt- u. Schweiss G. m. b. H., 531,288, 7/5/29.
Arrangement of the electrodes of electrically heated rotary furnaces. A. Johnson & Co., 531,350, 12/8/29; Sweden 12/10/28.
Interchangeable resistance heating for electric heat treating furnaces with several heating zones. E. F. Russ, 531,351, 11/28/29.
Means for the simultaneous operation of several arc furnaces in one plant Akt.-Ges. Brown, Boveri & Cie., 531,349, 2/5/29.
Induction furnace with laterally situated, completely full channel. H. Zepernick, 531,302, 1/18/30.
Method of cooling the coils of induction furnaces. Société Générale d'Applications Electro-Thermiques, 531,352, 3/28/30; France 3/27/29.
Means for operating furnaces. Allgemeine Elektricitäts Ges., 531,353, 4/18/30; U. S. 4/17/29.
Electric resistance welding machine with controllable welding voltage. F. Hellmuth, 531,354, 5/9/29.
Means for welding base plates to iron ties. Siemens-Schuckertwerke Akt.-Ges., 531,062, 4/14/26.
Furnace installation consisting of a reverberatory furnace and a charging shaft through which the waste gases flow from the former. F. Wüst, 531,064, 8/7/26.
Tilting, gas- or oil-fired hearth melting furnace. W. F. Sklenar, 530,914, 8/14/29; Great Britain 10/22/28.
Melting furnace for cast steel, malleable cast iron, enameling, etc. H. Tholen, 531,065, 9/16/27.
Furnace which tilts about an axis passing near its tap hole. Siemens & Halske Akt.-Ges., 531,146, 1/20/29.
Remelting furnace for scrap linotype metal and other cast metal. Maschinenfabrik Winkler, Fallert & Co., 531,310, 6/28/30.
Drying furnace for foundries. H. Küppers, 530,985, 8/4/27.
Wind regulating device for cupolas. J. E. Fletcher, 530,986, 5/11/30; Great Britain 5/24/29.
Device for protecting the metal issuing from melting pots against oxidation. Felten & Guilleaume Carlswerke Akt.-Ges., 531,022, 5/22/30.
Hand rammer. H. Leis, 530,915, 3/10/29.
Process and device for making sand molds for pipes and similar castings, by compressed-air rammers. K. Pardun, 531,023, 2/15/30.
Jolt molding machine. G. Zimmermann, 531,024, 12/24/29.
Process and molding machine for filling molds and core boxes with molding sand. A. Stahn, 531,025 (Addition to 524,373), 7/30/30.
Gas-absorbing composition for facing molds for making fluid-tight metal castings. F. Grotthaus, 530,916, 3/6/29.
Knock-out device for centrifugally cast pipes. Bayerische Berg-Hütten- u. Salzwerke Akt.-Ges., 530,917, 1/11/30.
Pouring trough for centrifugal molds rotating about a horizontal axis. Buderusche Eisenwerke, 530,918, 9/2/30.
Process for making composite castings. G. Pemetzrieder, 530,919 (Addition to 525,225), 5/9/30.
Process and machine for making centrifugally cast pipes. Ferric Engineering Co., 531,106, 9/25/29.
Process and device for making cylindrical bushings with a hardened inner surface. T. R. Pawlikowski, 531,107, 9/13/29.
Process for making hollow ingots by centrifugal casting. Vereinigte Stahlwerke Akt.-Ges., 531,174, 10/17/29.
Introduction of gases, vapor or liquids into molten baths at high temperature. F. Krupp Akt.-Ges. Fried. Alfred Hütte, 531,315, 6/12/29.
Working up alloy scrap. P. Kemp, 531,066, 5/12/28; Austria 6/23/27.
Process for detinning tin plate scrap or other tin-bearing material. E. Kardos, 531,112, 8/2/29; U. S. 8/30/28.
Process for improving alloys containing copper as the major component, nickel or cobalt or a metal of the platinum group, and silicon. Metallges. Akt.-Ges., 531,304, 4/18/25.
Device for dipping steel and other metal pipes, bars and the like for the purpose of pickling, cleaning, galvanizing, etc. The Perfecta Seamless Steel Tube & Conduit Co. (1923), Ltd., *et al.*, 531,036, 4/17/29; Great Britain 5/10/28.
Device for the continuous spraying of molten substances. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 531,069, 12/30/28.
Electrically heated tunnel furnace with two trains of cars moving in opposite directions. L. Riedhammer, 530,993, 7/21/28.
Molding machine for making all kinds of cores, operated with compressed air. F. Rolff, 531,559 (Addition to 496,383), 12/17/29.
Molding machine, especially for foundries. G. Zimmermann, 531,594, 8/-30/30.
Casting mold made of ceramic material. Deutsche Ton- u. Steinzeug-Werke Akt.-Ges., 531,630, 12/28/26.
Method of heating the sink-heads or risers of ingots and castings. E. Schwarz, 531,412, 5/31/29.
Bimetal obtained by welding a sheathing of copper-zinc alloy to an iron core. Vereinigte Deutsche Metallwerke Akt.-Ges., 530,807, 4/21/27.
Gas cut-off for welding burners. J. B. Barge, 531,512, 5/8/28; France 11/-29/27 & 3/30/28.
Rolling mill for rolling shapes. F. Möller, 531,611 (Addition to 513,122), 1/8/31.
Process for making steel rods. Stahlwerke Westig Akt.-Ges., 531,514, 12/-28/30.
Process for making metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 531,479, 2/13/30.
Process for making molybdenum carbonyl. Same patentee, 531,402, 1/21/30.
Process and means for making steel in the basic converter. P. Ries, *et al.*, 531,627, 1/9/29; Belgium 4/26/28.

Refractory lining for electric induction furnaces. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 531,621, 12/25/27.

Electric bright-annealing furnace. Siemens-Schuckertwerke Akt.-Ges., 531,484, 8/7/26; Austria 6/24/26.

Arrangement for connecting a non-ferrous induction furnace directly to a three-phase supply system. Hirsch, Kupfer u. Messingwerke Akt.-Ges., 531,409, 3/3/28.

Means for connecting carbon electrodes, especially those of electric furnaces. Siemens-Planiawerke Akt.-Ges. für Kohlefabrikate, 531,490 (Addition to 520,394), 12/2/28.

Regulating device for polyphase electric furnaces, having a compensated relay. Siemens-Schuckertwerke Akt.-Ges., 531,491, 4/29/26.

Heat insulation for melting crucibles. E. Brabandt, 531,368, 7/6/30.

Machine for making casting molds. E. O. Beardsley, *et al.*, 531,431, 10/11/29; U. S. 10/19/28.

Molding sand feed device for sand-projecting molding machines. S. Kurze, 531,593, 3/1/29.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

1001 **Large Castings.**—An article entitled "Massive Castings Made with Cores in New Steel Foundry" has been reprinted from Iron Age by the Foundry Equipment Company, Cleveland, Ohio. It is a description of the new plant of the General Steel Castings Corporation in which is installed the world's largest core oven completely designed and built by the Foundry Equipment Company. Interesting illustrations add to the article.

1002 **Gages.**—Circular No. 104 sent out by the Amthor Testing Instrument Co., Inc., 309 Johnson St., Brooklyn, N. Y., describes their mercury column gage for low pressure and vacuum. Several interesting features of this gage are pointed out and prices are given.

1003 **Metal Cleaner.**—The Udylite Process Co., Detroit, Mich., has distributed a folder announcing two metal cleaners prepared by them;—No. 7 for cleaning iron and steel prior to plating and No. 11, a low alkali cleaner for copper, brass and bronze, die cast and aluminum.

1004 **Foundry Equipment.**—Bulletin GEA-1413 of the General Electric Co., Schenectady, N. Y., is a 51-page booklet describing their electric equipment for foundries. This includes a page on lighting for foundries and a page on X-ray equipment for radiographic inspection. The same company has sent out several small leaflets, one devoted to their soldering iron, one to their heating devices and another to their controllers.

1005 **CO_2 Meters.**—A long period of research and development preceded the placing on the market of the L & N CO_2 meters but now the company is able to offer power plant operators a meter which will measure CO_2 to an accuracy within one-half of one per cent, while requiring comparatively little attention on the part of the operator. These meters are described in Bulletin No. 781 of the Leeds & Northrup Co., Philadelphia, Pa.

1006 **Electric Furnaces.**—The Pittsburgh Electric Furnace Corp., Pittsburgh, Pa., has distributed a reprint of "Continuous Melting from Cold Stock of Gray Iron in Electric Furnace" which is a paper presented by N. L. Turner at the 1930 Convention of the American Foundrymen's Association. This is a description of one of the company's furnaces which is in operation at the Beach Foundry, Ltd., and gives complete operating data and costs.

1007 **Cadalyte.**—A number of facts about this process and product for cadmium plating are noted in a leaflet sent out by the Grasselli Chemical Co., 629 Euclid Avenue, Cleveland, Ohio.

1008 **Potentiometers.**—The Leeds and Northrup Type K potentiometer is a thoroughly standardized instrument for measuring electromotive force with high precision and has a diversity of application. It is described and illustrated in Bulletin No. 755 sent out by the company.

1009 **Gear Blanks.**—A single page bulletin describing gear blanks made of arc-welded rolled steel has been sent out by Lukenweld, Inc., Division of Lukens Steel Co., Coatesville, Pa. This short bulletin is preliminary to a more complete engineering bulletin to be published later.

1010 **Udylite.**—Several interesting and unusual uses for this plating are brought out in the July issue of the Udylite News, published by the Udylite Process Co., 3220 Bellevue Ave., Detroit, Mich.

1011 **Metalayer.**—This is a process and apparatus for simultaneously melting, atomizing and spraying on any surface, coatings of any of the commercial metals. An attractive pamphlet illustrating applications of the process for both everyday and special coating work may be procured from the Metals Coating Company of America, 497 N. Third St., Philadelphia, Pa.

1012 **High Pressure Castings.**—An article with this title is a feature of the June issue of Nickel Cast Iron News, published by the International Nickel Company, 67 Wall St., New York, N. Y. This issue also contains number seven of their "Intimate Chats on Metallography," and part II of "Nickel and Nickel-Chromium Cast Iron" by Dr. Merica.

1013 **Precision Borer.**—Catalog No. 534 of the Societe Genevoise d' Instruments de Physique, for whom the R. Y. Ferner Co., Washington, D. C., are the American agents, describes the latest model of their type MP-3C SIP precision borer for the locating, drilling, boring and checking of work-pieces. It shows several new features of these machines added since the first of this type was exhibited at the Power Show last December, which includes drive by motor mounted vertically on the side of the machine, increased height below the cross rail, and a greater range of boring and drilling speeds. This machine has capacity for boring pieces 12" x 18" at one setting.

1014 **Testing Machines.**—Alfred Suter, 200 Fifth Avenue, New York, N. Y., is the American agent for Losenhausenwerk, Düsseldorf, Germany, manufacturers of testing machines of all kinds. A loose-leaf catalog, prepared by the German company, illustrates their different machines, including hardness testers, measuring devices, fatigue testing machines, etc.

1015 **Material Handling.**—An interesting article on this subject is found in the August issue of "Better Methods" published by the Beardsley & Piper Co., 2541 N. Keeler Ave., Chicago, Illinois.

1016 **Nitralloy.**—The Associated Alloy Steel Company of Cleveland has issued several new pamphlets in their Technical Bulletin Series. They are: "The Straight Chromium Stainless Irons and Steels," "Fabrication of Nevastain, Nirosta and KA2," "Resistance of Nevastain, Nirosta, KA2 and KA4 against Chemical Attack" and "The Physical Properties of Nevastain, Nirosta and KA2." These booklets are full of valuable material for those interested in these products.

1017 **Steels in Special Shapes.**—Cold finished steel bars can be drawn into a variety of odd and unique shapes twenty-four of which are illustrated in a book prepared by the Union Drawn Steel Company of Beaver Falls, Pa. These shapes can be produced with an accuracy of plus or minus 0.002" and their use will lower manufacturing costs and add to the quality of the finished product.

1018 **Metal Testing Machinery.**—Catalog 390 of Louis Schopper, sent out by Testing Machines, Inc., 314 Broadway, New York, illustrates measuring appliances for investigating the strength of materials. Machines for carrying out tests respecting tensile properties, compression, bending, etc., Ball hardness testers and pendulum impact testers are described.

1019 **Furnaces.**—The Parker-Kalon Corporation, 200 Varick Street, New York, has prepared a pamphlet describing their pot furnaces for case hardening by cyanide, heat treating, etc. A drawing is included which shows details of construction and operation. The furnace can be used equally well for tempering, annealing, drawing and blueing.

1020 **Cutting Oils.**—The rapidly increasing use of alloy and other special steels places an added burden on machine tool lubrication and so D. A. Stuart & Company, 2727 South Troy Street, Chicago, have developed unique oil products especially designed for present day conditions. A 62-page booklet telling about them is entitled "The Straight Line to Metal Working Efficiency."

1021 **Tungsten Carbide.**—"Firthite" is the name the Firth-Sterling Steel Company, McKeesport, Pa., have given to their cemented tungsten carbide. They have prepared an attractive booklet which lists uses for this product and gives reports of actual performances of Firthite tools. A price sheet for them can also be obtained.

1022 **Die Casting Machine.**—A folder describing their new size automatic die casting machine has been sent out by the Madison-Kipp Corporation, 20 Wauseba Street, Madison, Wis. This machine—size 12 x 16—is larger and more massive, for a larger range of work and increased production in multiple cavity dies. It is also a precision machine for high production of die castings in all standard alloys.

1023 **Rustless Iron.**—The Superior Steel Corporation, Pittsburgh, Pa., make several different brands of rustless iron and have sent out a booklet which gives the physical properties of the various kinds and shows a number of uses of each. The same company produces a new "Superior Metal" which is said to be ideal for a bright rustless surface that always looks new and is resistant to denting, scratching and corrosion. A folder telling about it is also available.

1024 **Carbonal Process for Carburizing Steels.**—This is the title of the new 12-page Bulletin 931 just published by the Hevi-Duty Electric Company of Milwaukee. The bulletin describes the results and advantages of the Carbonal Process of carburizing in the electric vertical carburizing furnace.

1025 **Hydraulic Tables.**—The Baldwin-Southwark Corporation, Philadelphia, is preparing a series of bulletins, No. 25 of which is intended for those engaged in the design or use of hydraulic equipment. An effort has been made to include data on subjects most frequently needed by such men. The data have been collected from many sources and some have never before been published.

1026 **Heat Treating Furnaces.**—A recent leaflet issued by the Surface Combustion Corporation, Toledo, discusses an installation of their furnace in which fifty axles per hour are normalized and hardened. Illustrations and performance data are given.

1027 **Cold Finished Bar**—Joseph T. Ryerson & Sons, Inc., Chicago, have issued a bulletin recently describing the wide variety of shafting, screw stock and open hearth case carburizing steels in use to-day. Each of these is explained in a non-technical manner, telling what each is used for and why it serves certain purposes to the best advantage. This is Bulletin A.

1028 **Fahralloy.**—An interesting leaflet published by the American Manganese Steel Company, Chicago Heights, tells the story of Fahralloy and its many heat and corrosion resistant applications.

1029 **Furnaces.**—The Electric Furnace Company, Salem, Ohio, has issued a folder illustrating and listing several electric and fuel fired furnaces of the various types recently installed in steel plants.

1030 **Plykrome.**—This is the trade name for a stainless composite steel made by the Plykrome Corporation, 225 Broadway, New York, into tanks, tubes, piping, retorts, etc., and for other general anti-corrosive purposes. It is a stainless steel veneer on a backing of inexpensive mild steel and may be fabricated into tanks, tubes, piping, retorts, etc., and used for other general anti-corrosive purposes.

1031 **Melting Machine.**—The "Schwab" continuous melting machine for lead, tin, stereotype metal, aluminum, zinc, etc., has a full automatic temperature control and greatly increased thermal efficiency. A folder describing it may be procured from Industrial Welded Alloys, Inc., Newark, N. J.

1032 **Castings.**—For unusually hard service the Chicago Steel Foundry Co., uses Evansteel in castings, for high temperature, Pyrasteel. They have sent out a small leaflet giving the physical properties of these alloys. The company's address is Kedzie Ave. at 37th St., Chicago.

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Sixty section editors and abstractors cover over 400 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstracts appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important. An improvement we hope to make in the METALLURGICAL ABSTRACTS in the near future is the cross-indexing of articles, which belong under several sections. Some of the sections are descriptive and some are self-explanatory and we have so labeled them.

CLASSIFICATIONS

0 (General). Under this heading we classify all abstracts which are of interest to the metallurgical industry in general. Compare this with Section 20—miscellaneous.

1, 2, 3 (Properties of Metals, Non-Ferrous and Ferrous Alloys). An article goes under one of these heads when the properties are emphasized and not the method of determining them.

4 (Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys). This takes articles on weather resistance, resistance to acids, etc., and protection against them.

5a (Structure of Metals & Alloys—Metallography & Macrography). An article would go in this group if it discussed the microscopic or macroscopic study of metals and alloys, or the determination of constitutional diagrams, critical points, etc.

5b (Structure of Metals & Alloys—Structure and X-Ray Analysis). This group includes articles dealing with the structure of metals and alloys as determined by X-ray analysis and X-ray examination.

6 (Physical, Mechanical & Magnetic Testing). If an article emphasizes the method of determining the properties of metals rather than the properties them-

selves it belongs in this section. The abstracts on fatigue appearing under this section are prepared with the coöperation of the Fatigue Research Committee of the American Society for Testing Materials.

7a (Electro-Chemistry—Electroplating). This will include articles on the electrolytic plating of metals.

7b (Electro-Chemistry—Electrometallurgy). This relates to the electrolytic recovery and refining of metals.

8 (Metallic Coatings Other than Electroplating). Articles on galvanizing, metal spraying or dip coating would come in this group.

9 (Industrial Uses and Applications). If the application of the metal is stressed rather than the properties the article belongs in this section.

10 (Heat Treatment). If heat treatment in general is discussed the article would be classed under section 10; if, however, any distinct operation is stressed it would go under the corresponding subhead.

11 (Joining of Metals and Alloys). The explanation for this group is similar to that for section 10.

12 (Working of Metals & Alloys). We feel that the divisions in this group are self-explanatory to men in the metals industries. We might say, though, that an article is classified under 12j (Cold Working) only when it will not fit under one of the other heads—for instance, an article on cold rolling would be put under 12c, rolling.

13 (Defects). This section includes articles dealing with inclusions, segregations, cracks, pinholes, blowholes and failures.

14 (Chemical Analysis). If the method of analysis is emphasized the article goes here.

15 (Historical & Biographical). Self-explanatory.

16 (Economic). Articles in this group are devoted to economic trends, savings, cost estimates, etc.

17 (Plants & Laboratories) This section includes descriptive articles.

18 (Machinery & Supplies). This includes descriptive articles.

19 (Bibliographies). Self-explanatory.

20 (Miscellaneous). This takes in all scattered articles which do not belong anywhere else.

21 (Laboratory Apparatus). Purely descriptive articles belong here. If results or processes are given they would go under 6 or 14.

22 (Foundry Practice & Appliances). This is self-explanatory.

23 (Furnaces & Fuels). This takes in descriptive articles. Otherwise they go under 10, heat treating, 10b, annealing, etc.

24 (Refractories & Furnace Materials). This section is hand-in-hand with 23. Furnace men should read both of them.

25 (Gases in Metals). This is self-explanatory.

26 (Inspection). This includes articles dealing with inspection, pure and simple—not X-ray or microscopic analysis.

27 (Effects of Elements on Metals and Alloys). Articles dealing with the effect of the addition of different chemical elements to metals and alloys are included in this group.

28 (Instruments & Controllers). Descriptive.

29 (Effect of Temperature on Metals and Alloys). This section is prepared in conjunction with the Joint High Temperature Committee of the A. S. T. M. and the A. S. M. E.

30 (Leaching). Self-explanatory.

31 (Reduction Metallurgy). This would include articles on blast furnace practice.

32 (Non-metallic Coatings for Metals and Alloys). Articles discussing painting, enameling, lacquering, etc., belong here.

◆ ◆ ◆ ◆ ◆

It has been our purpose in this outline to make our scheme of classification apparent to our readers and so, perhaps, make the abstract section more useful. If you have any questions pertaining in any way to the abstracts, write to us. We shall be glad to answer them in detail.

The classification number at the end of each abstract will be of assistance in mounting them on file cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

GENERAL (0)

Recent Investigations on Metals. (Nouvelles Recherches sur les Métaux.) EDMOND MARCOTTE. *Arts & Metiers*, Vol. 83, May 1930, pages 210–215.

A brief review of recent investigations carried out in France on protective coatings for metals, detection of internal stresses, annealing of steels in vacuum and tensile tests of nickel and nickel-chromium steels at 450° C. WHB(0)

Manganese Steel and Its Developments. R. HADFIELD. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 261–272.

Brief and very general résumé. HWG(0)

Applications to Iron & Steel Production—Annual Report of the Committee on Applications to Iron & Steel Production. A. C. CUMMINGS, *et al.* *Electrical Engineering*, Vol. 50, July 1931, pages 590–593.

Electric developments in the iron and steel industry during 1930 are traced, particularly in d.c. motors, synchronous motors and auxiliaries. WHB(0)

On Damascene Steel "Taban" and "Khorassan." N. T. BELAIEW. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 111–114.

General discussion with photographs of the two types of blades referred to. HWG(0)

Materials and Structures. By E. H. SALMON. Longmans, Green & Co., New York, 1931. Cloth, $5^3/_4 \times 8^1/_2$ inches, 638 pages. Price $6.00.

The first 391 pages deal with the mathematical calculation of stresses. The next 200 pages discuss the strength of metallic materials. A large number of references to the literature are given so that the student is not led to believe that all the important information is given in the book. In general, this section is moderately well up to date. There are some slips, as it is stated that the steel charge in the ordinary electric steel furnace is heated by the resistance of the charge, and that steel of 0.05–0.25% C cannot be hardened by heat-treatment.

The 18–8 type of steel is dismissed with 3 lines and Mo is not included among alloying elements for steel. On the other hand, the CuCr type of structural steel, the Meyer hardness index and Moser's work on impact specimens of varying widths are mentioned.

A chapter is devoted to endurance testing, in which the main points are dealt with and the effect of keyways, etc., mentioned. "Accelerated" test methods are only mildly condemned. Another chapter relates to high temperature properties, but a curve of creep data from tests lasting only 32 hrs. is shown without comment. The reader is not likely to grasp, from the discussion given, the essentials of creep testing that are necessary for precision. The impression one gets from this part of the book is that the author has read quite widely in the literature of physical testing of metals, but has not had much personal experience with a good many of the tests mentioned.

The last 30 pages are an "Introduction to the Study of Metallography." This is rather sketchy and while it serves to give the budding engineer some idea of the subject and its relation to the engineering properties of metals, it seems doubtful that he will be able to grasp very much of it.

The book gets weaker as one nears the back. The materials testing and metallographic sections seem to be put in because the author feels that they should be included in a course in theory of structures, rather than because he has much personal interest in them. Nevertheless the book is better balanced than if those sections had been omitted, even if they are less authoritatively dealt with than the mathematical section.

The selected bibliographies are rather well chosen and the reader can follow up, from the works of good authorities, the subjects that are none too authoritatively dealt with in this work. On the whole, it should be a rather good engineering text book, but as a reference book for metallurgists it is somewhat elementary and its mediocrity is only relieved by the fact that it is fairly well up to date.—H. W. Gillett (0)-B-

Modern Developments in Alloy Steels. (Neuzeitliche Entwicklung des Edelstahls.) P. GOERENS. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 285–324.

Includes Discussion. Furnace practice is first briefly discussed. The idea of vacuum melting for quality steel is mentioned approvingly. Aging-brittleness and temper-brittleness are mentioned. Structural steels are tabulated as follows:

Kind	Composition % C	Mn	Si	Cu	Cr	Y.P. lbs./in.²	T.S. lbs./in.²	Elongation %
No. 27	0.12	0.40–0.45	0.02–0.05			31,000	52,500	22
No. 48	0.30	0.55	0.12			41,000	68,000	18
Si	0.15	0.80	0.80			51,000	68,000	20
Cu-Cr	0.20	0.80	0.25	0.65	0.50	51,000	68,000	20
Cu-Mn	0.20	1.30	0.40	0.50		51,000	68,000	20

The properties of various heat-treated C, Ni-Cr, Ni-Cr-Mo or W and Cr-Mo-V steels are given. High temperature creep testing and wear testing are very briefly mentioned, as are magnetic properties. High speed steels are mentioned and the statement made that W can be substituted wholly or partly by Mo. Tungsten carbide tools, corrosion resistant steels, heat resisting alloys and nitriding steels are all briefly dealt with. In discussion Kjerrman pointed out the importance of "body" in steel. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 687. HWG(0)

The Engineers Vest Pocket Book. W. A. THOMAS. W. A. Thomas Company, Chicago. $3 \times 5^1/_2$ inches. Price $3.00.

Contains tables and information on mathematics, statics, dynamics, strength of materials, building construction, mechanical design, heat, hydraulics, chemistry, physics, electricity, transportation, surveying and costs.—W. A. Tucker (0)-B-

Iron and Steel (Eisen und Stahl) 97 photographs by Albert Renger-Patzsch with an introduction by Dr. Albert Vögler. Published by Hermann Reckendorf, Berlin, 1931. Bound, $8^1/_2 \times 12$ inches, 84 pages. Price 7.50 R.M.

Albert Renger-Patzsch is at present considered the best industrial photographer in Germany. The subject of iron and steel is divided into several groups of subjects. I. The production of iron and steel shows views in the blast furnace and Bessemer plants; II. In the rolling mill; III. In the foundry and forge shop; IV. In machine construction; V. In marine construction; VI. In bridges; VII. In steel structures; VIII. In cranes; IX. The working of iron and steel.

The photography is unquestionably the work of an artist and the publisher has assisted by executing a printing masterpiece.—Richard Rimbach (0)-B-

Coöperative Technical Research in the Steel Industry. F. N. SPELLER. *Iron Age*, Vol. 127, June 18, 1931, pages 1967–1971.

Includes discussion. Abstracts of a paper read before the American Iron & Steel Institute, May 1931. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 159. VSP(0)

Properties of Metals (1)

Thallium. ALICE V. PETAR. *Information Circular* 6453, *U. S. Bureau of Mines*, June 1931, 6 pages.

The properties, occurrence, uses, production and markets of thallium are discussed. 26 footnote and bibliographic references. AHE(1)

New Data Relative to the Independence of the Hardness and the Hydrogen Content of Electrolytic Metals. (Nouvelles données relatives á l'indépendance de la dureté et de la teneur en hydrogéne des métaux électrolytiques.) GUICHARD, CLAUSSMAN, BILLON & LANTHONY. *Comptes Rendus*, Vol. 192, May 4, 1931, pages 1096–1098.

The authors continue the discussion of the relationship between the hydrogen content of electrolytic metal and its hardness, which has been the subject of controversy between them and Guillet and Cournot. They bring forward evidence to prove that no such relationship exists, quoting the results of experiments on 5 different samples of electrolytic iron and also on other larger amounts of the same material. OWE(1)

The Geo-Chemistry of Rhenium. (Die Geochemie des Rheniums.) I. & W. NODDACK. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 154, Apr. 1931, pages 207–244. 15 references.

The authors consider at length the physical and chemical properties of rhenium and draw conclusions in regard to the geo-chemical behavior of this "rare element." The distribution of rhenium in the earth crust as well as in the cosmos is established by chemical analyses of a great variety of minerals (about 1600) and of some 60 meteorites, respectively. Furthermore, 1200 X-ray spectrograms were taken. The most important results of the exhaustive research are tabulated. Stress is laid on the occurrence of rhenium in sulphuric minerals. EF(1)

The Electrical Resistivity of Silicon. (Sur la résistivité électrique du silicum.) CU. BENDEL. *Comptes Rendus*, Vol. 192, Mar. 30, 1931, pages 802–804.

The author describes the results of experiments on the electrical resistivity of silicon, in which he used silicon containing about 0.1% of iron, a commercial product containing 1.4% of iron and a ferro-silicon of which the iron content was as much as 8.5%. The effect of iron upon the electrical resistivity of pure silicon was shown to be quite considerable, the mean value for the electrical resistivity of the sample containing 0.1% iron being 0.267 ohms-cm. For the other samples the following values were obtained: 0.069 for the 1.4% iron alloy, and 0.035 for the 8.5% iron alloy. OWE(1)

The Influence of Purity on the Variations of the Mechanical Properties Produced by Rolling and Annealing of Aluminum. (Influence de la purete de l'aluminium sur la variation de ses proprietes mechaniques par lamination et par recuit.) JEAN CALVET. *Revue de Métallurgie*, Vol. 28, Mar. 1931, pages 162–164.

Physical properties of very pure (Hoope's)aluminum and commercial aluminum were compared in cast and severely rolled state before and after several heat treatments. For cast metals the best annealing temperature is 400° C. for purer metals and 350° for commercial grades. The full influence of annealing is developed in very pure aluminum at a lower temperature (200–250°) than in commercial alloys. JDG(1)

Magnesium. Industry's Lightest Structural Metal. JOHN A. GANN. *S. A. E. Journal*, Vol. 28, June 1931, pages 653–668.

After reviewing briefly the history of the aluminum and magnesium industries, the author describes foundry practice in the production of magnesium and magnesium-alloy castings, their heat-treatment and the effect of various fabrication processes on the microstructure and physical properties. The general classes of commercial magnesium-base alloys now in use in this country are discussed at some length with particular reference to the combination of extreme lightness with good physical and mechanical properties that is obtained. Applications of magnesium alloys in the aircraft and automobile industries are outlined in a section of the paper. Many of these are illustrated. In conclusion the author states that the importance of magnesium as a structural metal is now being recognized, especially as the factors that have retarded its development and restricted its use are overcome. (1)

Status of the Knowledge of Super-conductivity. (Der Stand der Forschung über die Supraleitfähigkeit.) W. MEISSNER. *Metallwirtschaft*, Vol. 10, Apr. 10, 1931, pages 289–295; Apr. 17, 1931, pages 310–313; *Zeitschrift für Metallkunde*, Vol. 22, Sept. 1930, page 311.

A lecture before the German Society of Technical Physics and the Berlin Physical Society. Contains a bibliography of 75 references. A review of recent investigations. EF+CEM(1)

Some Experiments on the Strain-Hardening Induced in Iron and Stee by Certain Types of Mechanical Deformation—with Special Reference to D-Links for Colliery Tram Shackles. W. R. D. JONES. *Proceedings, South Wales Institute of Engineers*, Vol. 47, Feb. 26, 1931, pages 23–71.

Drilling does not introduce any irregularities in hardness in the vicinity of holes. Drifting and punching bring about hardened areas on the surface near the holes. Stressing of D-links has shown that drop forged links have considerably better properties than hand-forged and that mild steel is superior to wrought Fe. Mild steel showed greater shock resistance than wrought Fe by the Charpy impact test. There is a critical amount of work-hardening for each material as regards the best impact values. Annealing at 900° C. reduced the shock resistance. Includes 29 references. AHE(1)

The Freezing Point of Platinum. W. F. ROESER, F. R. CALDWELL & H. T. WENSEL. *Bureau of Standards Journal of Research*, Vol. 6, June 1931, pages 1119–1120.

In determining the freezing point of platinum on the International Temperature Scale, measurements were made of the ratio of brightness of black bodies maintained at the freezing points of gold and platinum. The black bodies used were hollow inclosures of fused thorium oxide immersed in the molten metals. Observations were made during the freezing of the metals. Two optical pyrometers were used and observations were obtained on two separate lots of pure platinum by three observers. The metals were heated in air using a high frequency induction furnace to secure automatic stirring of the freezing metals and to avoid contamination from furnace windings. The freezing point was found to be 1773.5° C. WAT(1)

Investigations of the Influence of Different Intermediary Annealing Temperatures on the Technological and Chemical Properties of Aluminum Sheet. (Untersuchungen über den Einfluss verschiedener Zwischenglühtemperaturen auf die technologischen und chemischen Eigenschaften von Aluminiumblech.) H. RÖHRIG. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 237–238.

The chemical resistivity of hard aluminum sheet can be made equal to that of properly soft annealed sheet by an intermediary annealing at 600° C. without impairing the technological properties. The final annealing temperature of 450° C. equalizes the various effects of the intermediary annealing. The sheet annealed at this temperature attains the best chemical resistivity and technological properties. The tests are given in detail. Ha(1)

The Temperature Dependence of Crystal Elasticity. II. (Ueber die Temperaturabhängigkeit der Kristallplastizität. II.) W. FAHRENHORST & E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XVIII, 1931, pages 26–30.

See *Metals & Alloys*, Vol. 2, Mar. 1931, page 62. (1)

The Preparation and Properties of Chemically Pure Metals. (Ueber die Herstellung und Eigenschaften chemisch reiner Metalle.) M. L. V. GAYLOR. *Metallwirtschaft*, Vol. 9, Aug. 15, 1930, pages 677–679.

Contains 7 references. In the preparation of pure metals very pure materials must be used, especially crucibles. SiO_2 crucibles are suitable for preparing Si, and Al_2O_3 crucibles for Fe, Mn and Cr. *Iron.* Electrolytic Fe made with very pure anodes from $FeCl_2$ solution can be obtained containing only traces of P. It oxidizes when exposed to air. Most of the oxide can be removed by heating for several hours at 900–1000° C. in a stream of dry hydrogen. It can be rolled into thin sheets. The last traces of O can be removed by treating the liquid metal with H at reduced pressure. The magnetic properties of electrolytic iron are better than commercial silicon steel but those of the iron treated in the liquid state are not as good. *Chromium.* Cr is prepared by electrolysis of 30% H_2CrO_4 and 1% H_2SO_4 solution in a water cooled lead tank, the tank forming the anode. The cathode is vertical tube, 3" dia., closed at the bottom, and rotated by a motor. In 10 g. of Cr prepared in this way no S, Pb, Al or Fe were found by analysis. H is removed by heating to 600° C. The O which it contains is not removed by melting in vacuum. The microscope shows that Cr_2O_3 is formed. This can be reduced by melting in a high frequency induction furnace at 1500–1600° C. in a rapidly circulating stream of H. The spectroscope shows no metallic impurities in the resulting metal. Electrolytic Cr is very hard and brittle, but after H is removed it becomes softer. *Manganese.* Mn prepared by the Thermit process, containing 3–4% impurities, is distilled in a vertical quartz tube in a high frequency induction furnace at 1–2 mm. pressure at a temperature just above the melting point. The distilled metal analyzes S nil, Si 0.002, Fe and Al trace, P 0.003, N <0.002. It is silver gray and very hard and brittle. When cooling below 800° C. it cracks. During cooling allotropic changes take place at 1191°, 1024°, 742° and 682° C. At one of the lower 2 points a volume change takes place which is the cause of the cracking. X-ray study shows a cubic crystal structure. The edge of one cube is 8.894 ± 0.002 A. U., density 7.44 g./cc. The elemental cube contains 58 atoms beta Mn, between 742° and 1024° also has a cubic lattice, 6.29 A. U. long, 20 atoms per cube. *Silicon.* The impurities in Si consist of silicates of Fe and Al and silicides of Fe, Ca and Mg at the grain boundaries. The Si is finely powdered in a mortar and treated with acid in a large beaker to dissolve the impurities. The residue is filtered, washed with water, treated with conc. HCl, diluted, filtered, washed and dried. Analysis: Insoluble 0.006, Fe 0.02, Al 0.02, Ca 0.009. Under the microscope the Si appears very pure, with twinned crystals. It is blue green, very hard and brittle. *Beryllium.* Be is prepared by electrolysis in a special apparatus from fused $BeF_2.NaF$ to which BaF_2 is added to bring the Ba up to 10–15%. A Cr Ni container and graphite anodes impregnated with pure NaCl are used. Be is hard, steel gray, has a high luster and is not attacked by the atmosphere. It is not ductile and is difficult to work. It is attacked by dilute acids and alkalies, but not by conc. HCl and H_2SO_4. Melting point about 1280° C. CEM(1)

Bismuth. PAUL M. TYLER. *United States Bureau of Mines Information Circular* 6466, July 1931, 19 pages.

Bismuth is discussed under the following headings: properties, uses, occurrence, extraction, production, imports, exports, foreign industry and lists of producers and consumers. 13 footnote references are given. AHE(1)

Progress in Production and Use of Tantalum. GEORGE W. SEARS. *Transactions American Institute Mining & Metallurgical Engineers*, 1930, pages 317–321.

Includes discussion. See *Metals & Alloys*, Vol. 1, Apr. 1931, page 471. (1)

Rhenium (and Masurium). PAUL M. TYLER. *United States Bureau of Mines Information Circular* No. 6475, July 1931, 17 pages.

Tyler discusses the properties, identification, occurrence, extraction and preparation, production and use of rhenium. Over 50 footnote and bibliographic references (with abstracts) are given. AHE(1)

I. The Specific Heats of Thallium, Calcium and Magnesium Measured to 10° Absolute. II. The Entropy and Chemical Constants of Magnesium from Spectroscopic Data. K. CLUSIUS & J. V. VAUGHEN. *Journal American Chemical Society*, Vol. 52, Dec. 1930, pages 4686–4699.

The specific heats of thallium, calcium and magnesium have been measured from 10° to 200° A. The vapor pressure constant of magnesium has been determined as 0.443 ± 0.1 and is found to agree very well with the statistically calculated value 0.493. The entropy of monatomic magnesium vapor at atmospheric pressure and 25° has been determined empirically at 35.29 units, while the theoretical value is 35.51. MEH(1)

Has Aluminum An Inversion Point? (Hat das Aluminium einen Umwandlungspunkt?) A. SCHULZE. *Elektrotechnische Zeitschrift*, Vol. 52, Mar. 12, 1931, page 358; *Zeitschrift für Physik*, Vol. 49, July 1928, page 146.

Experiments made with Al of 99.94% purity to higher than 600° C. shows conclusively that with increasing purity all discontinuities disappear, so that up to 600° C. aluminum does not possess an inversion point. Ha(1)

Tantalum. H. M. BASSETT. *Foundry Trade Journal*, Vol. 44, May 28, 1931, pages 366, 368.

A brief note on the reduction of tantalum and its uses. OWE(1)

The Dependence of the Alternating Current Resistance of Iron Wires upon Mechanical Tension. (Die Abhängigkeit des Wechselstromwiderstandes eiserner Drähte von mechanischer Spannung.) B. SAADIKOV. *Archiv für Elektrotechnik*, Vol. 25, June 19, 1931, pages 431–435.

A number of curves show the change of resistance of an extended iron wire at different tensions when an alternating current flows through the wire. For wires from 1 to 6 mm. diameter, a continued decrease was observed from 0 to 140 kg. tension, for ohmic as well as for the reactive resistance and, therefore, for the impedance. The reason given for this phenomenon is that a mechanical tension exerts an influence on the circular magnetic permeability of the Fe on which the alternating current resistance depends. Ha(1)

The Atomic Weight of Uraninite Lead from Wilberforce, Ontario, Canada. GREGORY PAUL BAXTER & ALLEN DOUGLASS BLISS. *Journal American Chemical Society*, Vol. 52, Dec. 1930, pages 4851–4853.

Value found for lead from uraninite is 206.195, the average of two determinations. MEH(1)

The Manufacture of Chemical Sheet Lead. R. S. RUSSELL. *Chemical Engineering & Mining Review*, Vol. 23, July 6, 1931, pages 389–391.

The British and the American standard specifications for "chemical lead" are regarded as not quite corr ct. Maximum limits for any one impurity are: Ag 0.002%, Bi 0.005%, Fe 0.003%, Sb 0.004%, Zn 0.002%, Cu 0.001%, Ni and Co together 0.001% Sn, Cd and As traces, and the Pb content obtained by difference must be no more than 99.99%. The rolling process is outlined. The fatigue limit of Pb determined on the Haigh machine is ±0.2 tons/in.², that is, 10,000,000 reversals of a stress of 0.2 tons/in.² will cause failure at ordinary temperature. At 100° C. the fatigue limit is about 4/5 that at ordinary temperature, and at 150° it is reduced to less than half. The remedy for fatigue failure lies in (1) elimination of vibration, (2) working at as low a temperature as possible, (3) preventing changes of temperature, and (4) supporting the Pb as completely as possible. The Atomic Weight of Uranium Lead from Swedish Kolm. GREGORY PAUL BAXTER & ALLEN DOUGLASS BLISS. *Journal American Chemical Society*, Vol. 52, Dec. 1930, pages 4848–4851.

An average atomic weight is given as 206.013 for uranium lead. MEH(1)

Tungsten. WILLIAM CRAWFORD HIRSCH. *Electrical Manufacturing*, Vol. 7, June 1931, pages 43–45.

The uses and properties of tungsten are presented. WAT(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Light Metals & Alloys, Cast and Wrought. Report of A. S. T. M. Committee B-7. J. B. JOHNSON, Chairman. *Preprint* No. 23, for June 1931 meeting, *American Society for Testing Materials*, 10 pages.

Tentative specifications for sand cast Mg-base alloys are proposed covering the following:

% Mg	% Al	% Mn min.	% Cu	% Cd	% Impurities	Tensile lbs./in.²	Elong. 2" in 2 in.	
Bal.	5.5–7.0	0.2	0.1 max.	.....	0.3 max.	24,000	4	
Bal.	6.5–8.5	0.2	0.1 max.	.....	0.3 max.	24,000	4	as cast
						29,000	6	heat treated
Bal.	1.7–2.3	0.2	3.5–4.5	1.6–2.4	0.3 max.	21,000	2	

From the former tentative specifications for Al-base sand cast alloys, the one of 8% Si, 3½% Cu is now omitted, and other minor changes made. Analytical methods for Mg alloys are to be drawn up in the form of a tentative standard. Tentative specifications for Al-alloy wire, rods and bars, Mg-base alloy sheet and wrought shapes have been recommended to the society, but have not yet been published. HWG(2)

Photo-Electric Effect of Aluminum and Aluminum Amalgams. (Der lichtelektrische Effekt des Aluminiums und der Aluminiumamalgame.) H. GERDING (University of Amsterdam). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. XI, Dec. 1930, pages 1–37.

Deals with the phenomenon of passification as met on surfaces of Al, Cr, Fe, etc. The photo-electric sensitivity of Al and its amalgams during scratching in vacuo is studied and the photo-electric fatigue by oxygen absorption interpreted. 70 references. EF(2)

Slowly Age-Hardening Silver Alloys. (Ueber vergütbare, schwer anlaufende Silberlegierungen.) J. A. A. LEROUX & E. RAUB. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 58–63.

The preparation and properties of silver-copper alloys for silverware modified by added metals (chiefly Zn, Cd and Ni) to diminish tarnishing were studied (cf. Jordan, *Technical Paper Bureau of Standards*, Vol. 21, 1927, page 459). An alloy with 83.5% Ag, 12.32% Zn, 4.18% Cu proved difficult to homogenize by annealing, very persistent coring obtaining. After hammering "in three directions," annealing at 520° C. for 2 hours produced a homogenized structure. The solubility of Cu in the Ag-Zn solid solution was determined. It was found that the diffusion of Cu in the Ag-Zn solid solution was much more rapid than in pure Ag. It was found that Cu dissolves to an extent of 7% in the Ag-Zn solid solution at 700° but not over 1% at 280°. These solubility determinations apply as well to an alloy with 92.5% Ag as to one with 83.5% Ag. These values approximate those for Cu in pure Ag, and in this sense Zn seems simply to replace an equivalent amount of Ag. This diminishing solubility with temperature suggested a capacity for age-hardening which was confirmed by hardness and tensile strength measurements on an alloy (82.5% Ag, 12.32% Zn, 4.18% Cu) given a typical age-hardening heat-treatment. Curves are given showing the increase in hardness (from 50 to 80 Brinell hardness), decrease in elongation (60 to 30%) and increase in tensile strength (by approx. 6000 lbs./in.²) on alloys quenched from various temperatures and aged at 280°. The considerable scattering in values was attributed to the tendency of the growth of abnormally large grains. An attempt was made to decrease this tendency by adding other metals. Ni was found to be very effective. Photomicrographs are given showing the effect of Ni additions up to 1.5% upon the grain size. Age-hardening determinations were made upon the Ni modified alloy and the data are given in curves. Ni improves the mechanical and age-hardening properties of this alloy. It is shown that the addition of Ni makes diffusion slower and the aging process more sluggish. Comparative aging experiments were run on pure Ag-Cu alloys with 83.5% Ag which showed the aging characteristics to be quantitatively similar to those of the Ag-Zn-Cu-Ni alloy. The diffusion of Cu in Ag is rapid only above 600°. Alloys of Ag-Cd-Cu were also studied. Large amounts of Cd and small amounts of Cu produce a sluggishly aging alloy whereas smaller amounts of Cd and larger amounts of Cu produce a rapidly aging alloy. Ni accelerates aging in these alloys, but these alloys age more sluggishly than Ag-Zn-Cu-Ni alloys. A table of data is given showing the changes in mechanical properties of all these alloys upon aging. EF+RFM(2)

Copper and Copper Alloys, Cast and Wrought. Report of A. S. T. M. Committee B-5. C. H. MATHEWSON, Chairman. *Preprint* No. 21 for June 1931 meeting, *American Society for Testing Materials*. 8 pages.

Changes in the specifications for sheet high brass, to be discussed at the next committee meeting, have been proposed, namely, recognition of 2 grades, use of tensile test for determination of rolled temper, of grain size for annealed, explanation of Rockwell figures on all tempers, and recognition of 5 annealed tempers. A tentative specification for copper water tube is proposed, by which dimensions and bend test are set for standard (for plumbing) and extra heavy (for underground) service. Hydrostatic test to 6000 lbs./in.² is required. Phosphorus-deoxidized copper is called for. The composition is to be 99.9 Cu, minimum; 0.1 P, maximum.

Properties	Soft Annealed	Light Annealed	Hard Drawn
Tensile, lbs./in.²	30,000	32,000	42,000
Elong. in 4 in., %	25	25	....
Grain size, mm.	0.025 to 0.065	Under 0.035	....

Aluminum Brasses. (Les Laitons a l'Aluminium.) L. GUILLET. *Revue Aluminium*, Vol. 6, Mar.–Apr. 1930, pages 1069–1072.

Aluminum added to brass goes into solution in the constituents of the primary alloy. It is known that the addition of a third element to a copper zinc alloy gives a structure which is different from that of the primary alloy, although the phases found are always present in ordinary brasses. Experiments have shown that 1% of aluminum has the same effect as 6% zinc. In connection with this the author shows a method of calculating the quantity of an element to be added in order to give definite amounts of α and β-phases. The special brass has mechanical properties similar to those of ordinary brass having the percentage of copper to give them the microstructure of the special brass. The addition of aluminum gives a structure resembling a brass of lower copper content and increases the tensile strength, elastic limit and hardness while decreasing the elongation and reduction in area. In an aluminum brass of the same structure as the binary brass there is an increase in elastic limit and corrosion resistance. The tensile strength and elastic limit of brasses of the same microstructure are higher the greater the percentage of aluminum. Only brasses containing less than 60% copper can be hot rolled; the addition of only 0.8% aluminum to a 65% copper brass enables it to be hot rolled. (2)

Die Cast Metals & Alloys. Report of A. S. T. M. Committee B-6. H. A. ANDERSON (Chairman). *Preprint* No. 22 for June 1931 meeting, *American Society for Testing Materials*. 13 pages.

Contains report of activities of the committee. Proposed tentative specifications for 7 Al-base alloy die castings are as follows:

No.	Cu	Si	Ni	Fe(max.)	Ten. Str. lbs./in.²	Elong. % in 2″	Charpy ft.-lbs.	Rockwell E.
1	..	5	..	2	29,000	3½	4½	60
2	..	12	..	2	33,000	1½	2	80
3	2	3	..	2½	30,000	3½	5	60
4	4	5	..	2¼	32,000	2	2½	75
5	1½	1	2¼	2½	29,000	4	4½	55
6	4	1¾	4	2½	31,000	1½	2	75
7	8	1½	..	2½	....	..	..	..

Nos. 1 and 2 may contain up to 0.6% Cu, Nos. 1–4 and 7, up to 0.5% Ni, Nos. 1–6 up to 0.75, and No. 8 up to 1% Zn; all may contain up to 0.3% Mn and 0.1% Mg, and all but No. 7 up to 0.1% Sn, while No. 7 may contain up to 0.2% Sn. Other impurities up to 0.2% in Nos. 1–6 and up to 0.5% in No. 7 may be present. Only the composition is specified, the physical properties are given for information, and relate to die cast specimens, not those cut from die cast parts. Only one zinc base alloy is required to meet all service, production and cost requirements. For this, the purest of zinc (not over 0.02% total impurities, including Pb, Sn, Fe and Cd) is required, to produce stable castings. The 10-day water vapor aging test is considered most suitable for determining stability. The alloy, according to the proposed tentative specifications, is to contain 2½ to 3½% Cu, 3½ to 4½% Al, 0.02 to 0.10% Mg. The maximum impurities allowed are: Fe 0.10%; Pb 0.01%; Cd 0.005%; Sn 0.005%, other impurities 0.02%. Individual specimens on a round die cast specimen of specified dimensions must show 35,000 lbs./in.² tensile, ½% elongation in 2″ and Charpy impact, on a square specimen, of 4 ft.-lbs. The minimum average of 5 specimens must show 44,000, 2%, 6 ft.-lbs. After aging 10 days at 95° C. in a humidity cabinet free from wood or organic matter, the minima for the average of 5 are 30,000, ½% and ¾ ft.-lb. The average expansion in 5 castings thus aged must not exceed 0.0025 in. in any dimension less than one inch, or that expansion per inch in any larger dimension. There is appended a paper by Tobias. See abstract below. HWG(2)

Lead-Base and Tin-Base Alloys for Die Castings. F. J. TOBIAS (Newton Die Casting Corp.). Appendix I to Report of Committee B-6, A. S. T. M. *Preprint* for June 1931 meeting, *American Society for Testing Materials*, 3 pages.

Characteristic alloys of this class are:

	Sn	Cu	Sb	Pb	Tensile lbs./in.²	Elong. %	Brinell 20° C.	Brinell 100° C.	Sp. Gr.
Tin-base	85	7½	7½	..	10,000	1	30.2	15.3	7.53
Intermediate	60	3	11	26	7,800	1¼	27.7	10.2	7.98
Lead Base	5	..	15	5	8,000	1½	23.2	10.6	..
Pb-Sb	..	..	10	90	7,500	1	15.5	10.9	..

German experiments on an alloy of the lead-base type, but also containing 2½% Cu, and using 0.4% Ni instead of some of the Sb, are stated to have shown good hardness and tensile strength, but hard nickel-antimony compound crystals thrown against the die walls under pressure pitted the die. Some uses for alloys of each class are mentioned. Six references are cited. HWG(2)

Electrical-Heating, Electrical-Resistance and Electric-Furnace Alloys. Report of A .S. T. M. Committee B-4. D. HARVEY, Chairman. *Preprint* No. 20 for June 1931 meeting, *American Society for Testing Materials*. 18 pages.

Contains proposed tentative specifications for rolled or drawn 80 Ni, 20 Cr alloy (77–79 Ni; 19–20 Cr; maximum of other elements, Fe, 1½; Mn, 2½; C, 0.25; Si, 0.40; S, 0.03). This alloy is to be tagged with a yellow label. Similar specifications for 60 Ni, 15 Cr, 25 Fe are: Cr 14–18; Ni, minimum 57; maximum of other elements, Mn, 3; C, 0.25; Si, 0.40; S, 0.03; Fe, balance. This is to be tagged with red. A proposed tentative method for determining temperature-resistance constants is given. Work on life tests and accelerated life tests is in progress. A sub-committee is working on molding and foundry practice necessary to produce sound tension specimens for Ni-Cr-Fe cast alloys, on methods of test for thermal expansion, thermal conductivity and the relation of these properties to warpage. HWG(2)

Electrochemical Investigation on Aluminum and Alloys of Aluminum with Mercury. (Elektrochemische Untersuchungen an Aluminium und Legierungen von Aluminium mit Quecksilber.) H. GERDING (University of Amsterdam). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 151, Dec. 1930, pages 190–218.

No compound could be found in the system Al–Hg. A liquid and solid phase was established between 0.8 and 99.97 atomic % of Hg. The binary constitutional diagram Al–Hg was investigated by means of potential measurements of Al and its amalgams in solutions of acetyl-acetone. The potential difference between an amalgam with 2 phases and the extrapolated potential value of the "theoretical Al" amounts to 130 milli-volts. The normal potential value of this Al in an aqueous solution of aluminum chloride is −1.47 volts and −1.43 volts in an Al-sulphate solution. The electrochemical behavior of amalgams in acetyl-acetone is discussed and the formation of low-valence Al-ions is suggested. EF(2)

PROPERTIES OF FERROUS ALLOYS (3)

The Influence of the Cross Section of Ingots on the Mechanical Properties of Forged or Rolled Steel Bars. (Contribution a l'étude de l'influence de la section du lingot sur les proprietes mechaniques des barres forgees our lamines en acier.) A. PORTEVIN, E. PRETET & H. JOLIVET. *Revue de Métallurgie*, Vol. 28, Mar. 1931, pages 121–138.

Two ingots 40 and 21 cm. on the side were cast from several Ni-Cr heats and rolled according to the usual plant practice with the reduction of 4, 16 and 48 in the case of larger ingot and 4 and 12 for the smaller one. They were properly heat treated and studied under the microscope, macrographically and on a tensile strength machine. The irregularities due to crystallization in too large dendrites show their influence up to a certain minimum of deformation, which is largely dependent on the prominence of the dendritic segregations. In sound ingots the properties both transverse and longitudinal are not affected by the large reductions. They are detrimentally affected by impurities which might be present locally either as segregations, inclosed in certain areas of ingots, or in interdendritic spaces. Their presence is always dangerous, but particularly so in materials only slightly worked. The amount of deformation given cannot be used for prediction of the final properties. 18 tables and 29 photographs are given. JDG(3)

Tensile Properties of Cold-Rolled Bolts. (Festigkeitseigenschaften kaltgewalzter Schrauben.) W. REICHEL. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Apr. 11, 1931, pages 457–459.

The difference in the tensile properties of cut and rolled bolts is due only to the different method of threading. Both types are of equal value for all moderate stresses. The temperature occurring during the rolling of the thread is measured and its influence on the quality of the bolt is discussed. In general, the rolled bolt is superior to the cut bolt, especially in the refined state; the increase amounts, on an average, to 20%. At dynamical stresses, the rolled bolt is not quite as good as the cut bolt; the conditions under dynamic stresses have not yet, however, been sufficiently investigated. 15 references and microphotographs supplement the paper. Ha(3)

The Physical Properties of Fine Bolts. H. B. PULSIFER. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 273–312.

Paper read before the 12th Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion and is illustrated with 12 charts and 14 micrographs. The author presents a statistical study of the physical properties of bolts, Brinell, scleroscope, tensile strength, yield point and elongation. The spiral material of the thread outside the root diameter cuts down the elongation by stiffening the bolt giving a more abrupt fracture and wider scatter of results than would be obtained on a smooth test bar. Heat treating equipment, threading tools, sampling for test and the possibilities for improvements in the quality of bolts are discussed. WLC(3)

The Broad-Flanged Differdinger-Grey Steel Sections. (Die breitflanschigen Differdinger-Grey-Träger.) M. ROS. *Report* No. 52. *Eidgenössiche Materialprüfungsanstalt an der E. T. H. Zurich*, Aug. 1930, 34 pages.

Study of mechanical properties and allowable loads in Thomas steel of 0.06% C, 57,000 lbs./in.² tensile; 0.10% C, 64,000; 0.15% C, 71,000, made in certain broad-flanged sections. Segregation and heterogeneity were considered, and the necessity of finishing rolling above the critical point is emphasized. It is concluded that in properly made steel allowable stresses on these sections are:

Tensile Strength of Steel, lbs./in.²	Allowable Stress, lbs./in.² For Bridges	For Buildings
57,000	20,000	22,800
64,000	21,300	24,200
71,000	22,800	25,600

HWG(3)

Wrought Iron. Report of A. S. T. M. Committee A-2. H. W. FAUS, Chairman. *Preprint* No. 10 for June 1931 meeting, *American Society for Testing Materials*. 5 pages.

Slight changes in specification for stay-bolt, engine-bolt and other high-grade wrought iron bars are proposed. Grade C is to be termed B1 and its tensile requirements dropped, in 1¼ sq. in. or less section, from a maximum tensile of 54,000 to 53,000, over 1¼ sq. in. from 48,000–54,000 to 47,000–53,000, and reduction of area is dropped from 37 to 35%. On grade A, for flats, the reduction of area requirement is omitted. A sub-committee is planning for a symposium in 1932 on what constitutes "quality" in wrought iron. HWG(3)

Chromium-Manganese Steels. F. M. BECKET. *Heat Treating & Forging*, Vol. 16, June 1930, pages 750–754; *Iron Trade Review*, Vol. 86, May 15, 1930, pages 53–57; *Metal Stampings*, Vol. 3, June 1930, pages 543–544; *Rolling Mill Journal*, Vol. 4, May 1930, pages 219–220.

Steel Castings as a Material of Construction. (Der Stahlguss als Baustoff.) A. OEHLER, with discussion by A. ENGLER, J. WEISS and M. ROS. *Schweizer Verband für die Materialprüfung der Technik*. Report No. 36 of the Eidgenossische Materialprüfungsanstalt (Report of discussion No. 11), Dec. 1929, 34 pages, 35 figures.

A résumé of the properties of large steel castings, discussing porosity, cracking, design to obviate these, properties of properly annealed steel of 0.15–0.20% C; 0.25–0.30% C, and 0 50–0.55% C, made in the open-hearth, the converter and the electric furnace. Some data on Ni-Cr steels are included. Gating is discussed. Short-time tensile and impact tests on cast steel up to 500° C. are given. The article covers such a broad field that it cannot be adequately abstracted. HWG(3)

Some Notes on Blue Brittleness. LELAND RUSSELL VAN WERT (Harvard University). *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 404, 1931, 11 pages.

"Aging" of cold worked steel and "blue brittleness" are caused by precipitation of nitrides, oxides or carbides from supersaturated solid solutions. When steel is deformed at 200° or 300° C. the precipitation occurs immediately after deformation, thereby strengthening the steel as it is being tested. Torsion tests, in which load was automatically plotted against twist, were made at various temperatures. A stepped curve indicates alternate yielding followed by apparent elastic recovery, and is typical of steels in the blue brittle range. Pure (Yensen) iron at 300° C. showed small steps, indicating a small quantity of impurities. Izett steel at 300° C. gave even a smoother curve. Nitrided Armco iron gave a lightly stepped curve at 100° C., decidedly stepped curves at 200° and 300° C., and smooth curves above and below these temperatures. The same material when quenched from 575° C. gave stepped curves at room temperature, 100° and 200° C., but smooth curves at 300° and 400° C. Contains 11 references. JLG(3)

Nickel Cast Irons. (Ueber Nickelguss.) F. RENAUD. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 207; *Revue de la Fonderie Moderne*, Vol. 24, Nov. 25, 1930, pages 397–400.

Stainless Steel. HARRY BREARLY. *Proceedings Society of Chemical Industry of Victoria*, Vol. 30, No. 6, 1930, pages 368–384.

The properties of stainless steel are briefly discussed. Experiments are described and observations detailed on the general problem of corrosion, particularly the part which stainless steel has had in the simplification of that study. WHB(3)

On Quench-Hardening Properties in Some Iron Alloys. T. MATSUSHITA & K. NAGAWASA. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*. Part 2, pages 163–178.

In English. Expansion, critical point and magnetic curves are shown for steels of 0.15–0.20% C and 1 to 17% Cr. Also magnetic and hardness curves for five practically carbon-free Fe-Cr alloys of 2.4 to 19.6% C; quenching from the γ region is alleged to produce hardening. The quenching temperatures actually used are not given. Similar tests were made on three alloys of 0.05 to 0.10% Si, 0.03 to 0.07% Mn, with 0.14% C and 1% V, 0.14% C and 3% Mo, and 0.07% C and 5% W. Tensile curves are given for different tempering temperatures. The V and Mo steels gave maxima of about 160,000 lbs./in.^{2} tensile. HWG(3)

The Development of Structural Steels. (Die Entwicklung der Baustahle.) O. PETERSEN. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 213–229.

The importance of high yield point in structural steels is discussed and the progress in producing such steel reviewed. The use of higher carbon brings poorer workability. The high Si structural steel is prone to have surface flaws and does not show as high a yield point as is desired in heavy sections without using an analysis that gives too high an ultimate strength. The next step was to a Cu-Cr steel of 0.15% C, 0.25% Si, 0.80% Mn, 0.50–0.80% Cu, 0.40% Cr. This is more uniform in properties in different sections, and can be finished at a lower temperature than the high Si steel, its critical range being 120° C. lower. It has a certain corrosion resistance due to its copper content. Shapes rolled from this give a yield point of 53,500 to 61,000 lbs./in.^{2}, tensile of 76,000–84,000 lbs./in.^{2} with 22–24% elongation and 45–50% reduction of area, with an impact of 10 to 12 mkg./cm.^{2} A variation of this steel may contain about 0.80% Cr, 0.30% Cu and 0.40% Si. Still another high yield point steel contains 0.15% C, 0.5% Si, 1.0 to 1.5% Mn and 0.3 to 0.6% Cu. In this, the Si may be lowered to 0.3% and around 0.15% Mo be used. Such steels, in various sections, give 51,500–61,000 lbs./in.^{2} yield, 76,500–87,500 lbs./in.^{2} tensile, 21 to 26% elongation and 45–36% reduction of area. HWG(3)

Operating Results and Fields of Application of the Recently Produced Different Kinds of Malleable Iron. (Betriebsergebnisse und Anwendungsgebiete der neuzeitlich hergestellten verschiedenen Tempergussarten.) RUD. STOTZ. *Giesserei-Zeitung und Giesserei*, Vol. 18, Jan. 2, 1931, pages 1–8.

In Europe, especially in Germany, the designation "malleable iron," contrary to American practice, does not designate a material with definite properties. The consumer must become acquainted with the peculiarities and difficulties of production in order to avoid trouble in working. In the future, the American practice will probably be followed to a greater extent in making black iron instead of the white chilled iron which was formerly made exclusively. Many new applications can be found for this product; it can often replace steel castings. The mechanical properties and metallurgical structure of the 2 kinds of malleable iron are described and test results are given. 6 references. Ha(3)

The Thermal and Electrical Conductivities of Cast Iron. J. W. DONALDSON. *Foundry Trade Journal*, Vol. 45, July 2, 1931, pages 5–6.

Refers to the work of Masumoto on the thermal and electrical conductivities of cast iron and then discusses the results of an investigation of these same properties, which was reported upon by him in 1928. The author concludes that the investigations which have so far been carried out justify the view that the thermal conductivity of gray cast iron varies from 0.110 to 0.140 and decreases with increase in temperature. The conductivity of white cast iron is considerably lower, varying from 0.030 to 0.080. The conductivities of both gray and white cast iron are affected by composition. Heat treatment also changes the behavior of the material. The relationship between thermal and electrical conductivity (Wiedmann and Franz law) holds with a fair degree of accuracy for white cast iron, but when graphitization occurs in either white or gray iron, the relationship is definitely altered. The article is illustrated by two tables and one diagram. OWE(3)

New Chromium Steel Contains Zirconium Sulphide. F. R. PALMER. *Steel*, Vol. 87, July 24, 1930, pages 50, 52, 54.

Addition of 0.4% ZrS_2 to a corrosion-resisting steel containing about 0.1% C and 14% Cr facilitates the machining, grinding and polishing of the steel practically to the extent of commercial screw-stock. This grade of steel is being machined at surface speeds up to 150 ft./min. The sulphide confers non-galling properties on the steel, reducing scratching, seizing and galling. The steel is being used for many purposes. Use of ZrS_2 in steel intended for sheets, plates or cold-rolled strip is not recommended because the steel does not respond well in these forms to deep drawing or forming operations. For best machining properties, steel containing ZrS_2 is heated thoroughly at 1350–1400° F. and cooled in air. This gives a Brinell hardness of about 187. If the steel is hardened by quenching in oil from 1850° F., and drawing at 700° F., it will have a yield-point of 92,500 lb./in.^{2}, tensile strength of 127,000 lb./in.^{2}, elongation in 2 in. of 16%, reduction in area of 38%, Brinell hardness of 255, and Izod impact value of 22 ft.-lb. The corrosion resistance of the steel is equal to that of the same analysis without ZrS_2. It remains practically scale free to about 1200° F. Samples which had an average Izod impact value of 40.6 ft.-lbs. had an average value of 42.7 ft.-lbs. after being held in a furnace at 800–1000° F. for 6 months. ZrS_2 exists in the steel as tiny particles uniformly distributed throughout the metal. MS(3)

The Magnetic Properties of Perminvars. (Ueber die magnetischen Eigenschaften der Perminvare.) H. KUEHLEWEIN. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 72–88.

The property of the perminvar materials—that is the constancy of the original permeability up to comparatively high magnetizing fields—which makes them so valuable in the construction of instruments—is not yet fully explained. The following results can be stated as certain: 1. The different shapes of the hysteresis loops of perminvars all form a continuous series; 2. An increase of the perminvar character in the Elmen perminvar range can be obtained either by a greater contents of cobalt or by annealing at higher temperature; 3. Hysteresis loops of perminvar character can be obtained only if the cooling after annealing goes on very slowly; 4. In the system iron-nickel-cobalt another perminvar range exists besides that of Elmen which lies very close to the iron-nickel series; 5. The more pronounced the perminvar character of an alloy is the more difficult it is to demagnetize it; some kinds can be demagnetized only by annealing. Numerous diagrams illustrate the paper; 7 References. Ha(3)

The Alloys of Beryllium with Iron. (Die Legierungen des Berylliums mit Eisen.) WILH. KROLL. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 33–34.

It had been observed that Be-Ni-Cr steels assume a greater hardness by very slow annealing at a temperature of at least 700–750° C. At this temperature, the aging obtains a maximum for these steels after having been quenched in oil from 1200° C. The aging of the beryllium steels is due, very likely, to the different solubility of Be in the γ-iron or α-iron. See also *Metals & Alloys*, Vol. 1, Feb. 1930, page 383. Ha(3)

Weather-OMeter
and Metallurgy

In processes mechanical or chemical—in smelting, refining, reducing, or alloying metals—in the various industrial fields, the use of the Weather-Ometer for making weathering determinations and the study and measure of corrosion is becoming common practice.

The Violet Carbon Arc in the Corex D Glass Globe g ve light reaction that parallels natural sunlight so closely as to meet all ordinary scientific test requirements and the other natural weathering factors of rain—cold—heat—humidity—are reproduced under accelerated, controlled—measureable conditions that make possible accurate, scientific deductions.

We have recently published a new Treatise on Weather-Ometer and its industrial and scientific uses that will especially interest the Metallurgist. A copy will gladly be sent you if you will ask for Bulletin MA-11.

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosion of Cast Iron in City Soil. (Die Veränderungen des Gusseisens im Stadtgrund.) A. ROMWALTER. *Das Gas- und Wasserfach*, Vol. 73, Feb. 1930, pages 178–182.

Investigation on corroded cast iron pipes of under-ground piping. EF(4)

Method for Evaluating Results of Corrosion Tests. KARL PITSCHNER. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, page 974.

Abstract of paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 902. MS(4)

Protection of Iron Immersed in Aërated Salt Solutions and the Realization of an Evans' Cell. (Protection du fer plongé dans les solutions salines aerees et réalisation d'une pile Evans.) E. HERZOG & G. CHAUDRON. *Comptes Rendus*, Vol. 192, Apr. 7, 1931, pages 837–839.

The authors point out that a quantitative study of what may be termed an Evans' cell has not been made on account of the difficulty of forming cathodic or anodic surfaces on the entire electrodes. With the object of overcoming this difficulty they have designed a cell, a description of which is given in the paper. In this cell 2 plates of iron form the cathode and the anode, respectively. These plates are placed in compartments separated by a porous diaphragm, the plates prior to the experiment having been carefully polished to the same degree. The cathode is immersed in sodium hydroxide, the anode in ferric chloride or ferric sulphate. The cell is set in action by bubbling air around the cathode or by adding dilute oxygenated water to the hydroxide solution. The authors have noted that the potential rises slowly to about 0.15–0.20 volt and remains steady after several hours in the neighborhood of 0.4–0.43 volt. The experiments have shown that the current of such a cell is determined principally by the concentration of the oxygen in the neighborhood of the cathode, increasing with this concentration up to a certain limiting value. The authors have studied the effects of protection due to additions made to the corroding solution. They have found that a whole series of bodies: borates, phosphates, arsenates, bicarbonates, oxalates, citrates, acetates, etc., have a protective effect. This can be explained by the property which these bodies possess of forming such acid and basic compartments as are necessary for the building-up of a high voltage cell. A variety of potential-time curves are shown, these differing in their form according to the solution which is employed. An explanation is given of the various types of curve obtained. The authors point out that the device they have described enables a comparison to be made of the actions of seawater and sodium chloride solutions, the results obtained being in good accord with experiments made by measuring the loss of weight of iron after corrosion in these solutions. The article is illustrated by two curves. OWE(4)

Cadmium Plating vs. Corrosion-Fatigue. WILBER E. HARVEY. *Metal Industry*, N. Y., Vol. 29, Apr. 1931, page 175.

The following table lists the results obtained in testing cadmium plated steel:

	Engineering Experiment Station Cr-V Steel, lbs./in.²	Present Test 0.47% C Steel, lbs./in.²	Percentage Protection
Fatigue limit (air)	69,000	61,000	
Fatigue limit uncoated steel (water)	18,000	19,000	
Fatigue limit 0.0002″ Cd (water)	35,000		33.3
Fatigue limit 0.0004″ Cd (water)	42,000		47.0
Fatigue limit 0.00022″ Udylite (water)		45,000	62.0

Solubility of Zinc in Sulfuric Acid. F. W. HARRIS. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, page 696.

Abstract of paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Aug. 1930, page 688. MS(4)

On the Dissolution of Metals in Acids. (Ueber die Auflösung von Metallen in Säuren.) G. WALPERT (University of Münster). *Zeitschrift für physikalische Chemie*, Sec. A, Vol. 151, Dec. 1930, pages 219–233.

Experiments on Fe, Cr, Zn and Cd, the dissolution of which in acids after adding salts, acids and highly molecular materials is studied. The author concludes that his observations are based on the absorption phenomenon of "foreign matter" (Fremdstoffe). Owing to this, the primary reaction during the dissolution of metals must be an absorption of ions. EF(4)

Combating Wear of Tractor Parts. H. B. VEITH. *Machine Design*, Vol. 3, June 1931, pages 33–35.

Wear due to friction and the entrance of mud and water was efficiently overcome by means of a special lubricating system and washer at the end of the track roller shaft bearing box. Ha(4)

Corrosion and Heat Resistant Nickel-Copper-Chromium Cast Iron. J. S. VANICK & P. D. MERICA (International Nickel Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 923–942.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. A preliminary study of austenitic nickel-chromium cast irons led to the realization of their industrial possibilities and further study developed a valuable series of alloys containing 12–15% Ni, 5–7% Cu, 1.5–4% Cr, 1.0–1.5% Mn, Si 1.25% and total carbon 2.75% with low sulphur and phosphorus. These irons show good mechanical properties, satisfactory resistance to certain industrial corrosives and to heat. Various industrial applications are given and discussed. The thermal coefficient is 50% greater than for ordinary iron and has led to the use of this alloy for sleeves in automotive engines in connection with certain aluminum alloy pistons. WLC(4)

Corrosion Defects on Oil Tanks. (Korrosionsschäden an Oelbehältern.) TIBURTIUS. *Korrosion und Metallschutz*, Vol. 7, Mar. 1931, pages 49–53.

The author reports on two 10,000 m.³ oil storage tanks which failed in service due to corrosion. The drainage system of the surrounding pit did not work properly so that rain had free access to the bottom plate, which badly corroded and yielded when the storage tank was filled. The repair work on the tank is described at length and scientific laboratory tests are reported which indicate that coke and metal in the presence of water are liable to form "contact" and "concentration currents." EF(4)

Comparison of the Corrosion Resistance of Copper Steel and Plain Steel Railroad Ties. J. S. UNGER. *The Steel Maker*, Vol. 2, No. 1, 1931, pages 93–95.

The 2 steels had the following composition:

	Copper Steel Ties	Plain Steel Ties
Carbon	0.23	0.22
Manganese	0.48	0.52
Phosphorus	0.018	0.017
Sulphur	0.049	0.047
Copper	0.25	...

After 9 yrs. in service, the average loss of 10 ties of each kind was 19.4 lbs. for the copper steel and 41.9 lbs. for the plain steel tie. The foot flange showed a much less reduced section in the copper steel ties. Ha(4)

UNIVERSAL CORROSION-RESISTANT ALLOY

supplied as rough or finished castings

Particularly effective against the sulphur acids and compounds, ILLIUM likewise withstands other corrosives, both acid and alkali, to a degree equalled by few materials. Also resistant to heat, wear, impact and torque. It machines readily, takes high polish, is easily welded.

ILLIUM has been in successful use for more than 15 years. Its chemical and physical characteristics are known. Its advantages and limitations clearly defined. Its record is proof of its value.

RECOMMENDED FOR

Agitators	Filter Parts
Bobbins and Holders	Instrument Cases
Bombs	Kettles
Bolts and Nuts	Machine Parts
Buckets	Nozzles
Crucibles	Pipe Fittings
Dipping Baskets	Pump Parts
Fans	Racks
	Valve Parts

and other similar items

Do you have a corrosion problem in some process or in equipment which you sell? Let us quote from your patterns or drawings, or work with you in designing ILLIUM parts to eliminate the trouble. At least *investigate* ILLIUM'S possibilities. The coupon below is for your convenience.

Effect of Antimony in Aluminum Alloys. (L'influenza dell'antimonio nelle leghe d'Alluminio.) A. W. BONARETTI. *Metalli Leggeri*, Vol. 1, Jan.-Feb., 1931, pages 29–52.

Discussion of results of corrosion tests in sea water for 180 days on various aluminum alloys—especially the "K. S. see-wasser" type, with Mn, Mg and Sb as alloying elements, compared with alloys containing 8% Si or 4% Cu. The last 2 alloys were destroyed by corrosion while several of the "K. S." type were not much affected. Tensile tests were made after corrosion, the actual figures not being given, the results being stated to be no change in elongation and a slight improvement in tensile strength for an alloy with 3% Mg, 3% Mn and 1% Sb. (The usual composition of the K. S. alloy is given as 1.4% Mn, 2% Mg, 0.7% Si, 0.2% Sb). Somewhat similar alloys without Mg did not behave quite as well. The data appear to be taken from the work of Baumeister. No alloy was tested in which the 3% each of Mg and Mn were used without Sb. No definite proof is presented to show whether Sb is really useful. The cast Mn-Mg-Sb alloy is said to have 20,000–28,000 lbs./in.^{2} tensile and 2 to 5% elongation. Wrought alloys 28,000–42,000 and 3 to 18%. It is stated that for wrought material, the Sb should be raised to about 2%, and the Mg lowered to about ½%. No corrosion tests are cited for such an alloy. High temperature tensile tests on the cast alloy of 25,000 tensile, 2% elongation showed little change to 250° C.; from 250° to 500° C., the strength fell to 8500 lbs./in.^{2}, and the elongation rose to 18%. Many photographs of large castings, mostly for marine use are shown. In only a couple of cases, is it specifically stated that the castings were of the 3% Mn, 3% Mg, 1% Sb alloy. Photos are shown of specimens of this, of silumin, of the "German alloy" (10% Zn, 2% Cu) and the "American alloy" (6% Cu) after 180 days in sea water, alone, and of all but silumin after 120 days, in contact with bronze or steel, to show that attack is least on the "KS" alloy. The Puzzle of Corrosion. (Rätsel des Rosten.) DR. FREITAG. *Oberflächentechnik*, Vol. 7, Sept. 2, 1930, pages 162–163.

The familiar fact that iron from ancient times and the middle ages does not often show the least sign of rust or any other indication of corrosion is ascribed, in general, to a chance product of stainless material by certain additions. Several such examples are cited. Ha(4)

Some Factors Affecting the Corrosion of Buried Steel. F. L. BASSETT. *Gas Journal*, Vol. 194, Apr. 29, 1931, page 296; *Journal Society of Chemical Industry*, Vol. 50, May 8, 1931, pages 161–166T.

Gives discussion of paper presented before London Section of Society of Chemical Industry, April 13, 1931. MAB(4)

Anodically Oxidized Aluminum as a New Material for Electrical and Automobile Industry. (Anodisch Oxydiertes Aluminium als neuer Werkstoff für die Elektrotechnik und den Automobilbau.) KARL ALTMANNSBERGER. *Oberflächentechnik*, Vol. 8, May 5, 1931, page 101.

A new process for rendering aluminum or aluminum alloy sheets or shapes highly corrosion resistant was demonstrated at the International Automobile Show in Germany. The process was worked out by the United Aluminum Works and it differs materially from the English process. Thus, instead of using the pure 3% chromic acid as the electrolytic bath and employing progressively increasing voltage in the oxidation of aluminum, the German process applies a cold bath of arsenious acid, material involved as cathode. (By the English process, aluminum is used as the anode.) The first layer of aluminum oxide coating is produced by direct current and the final layer by alternating current. The coating produced also has high electric insulating power and is capable of absorbing the coloring substances permanently and uniformly. ER(4)

Corrosion of Iron and Steel. Report of A. S. T. M. Committee A-5. J. H. GIBBONEY, Chairman. *Preprint* No. 12 for June 1931 meeting, *American Society for Testing Materials*. 40 pages.

Contains reports of several sub-committees and accounts of work in progress. Among the projects in hand are; one looking toward specifications for plated coatings on iron and steel, in which 7000 specimens plated with Zn, Cd, Cu, Ni, Cr or combinations, are being prepared for outdoor exposure tests; one on methods of determining weight of coatings; one on the Preece test and stripping tests for Zn coatings; one on metal culverts, in which the specimens are to be put out in the spring of 1932; and one on embrittlement of galvanized structural steel on which experimental work is now active. Another major project is the study of methods of laboratory testing for prediction of service in the atmosphere, especially the SO_2-CO_2 simulated industrial atmosphere and the salt spray tests. Progress to date has not been encouraging, and it seems probable that if success is possible at all, it will be through the use of a flexible method in which the corroding agents are varied so as to duplicate different atmospheric conditions. Very valuable work by the sub-committee on total immersion tests is reported, in which material whose atmospheric corrosion in various localities is known by actual 5 years exposure, was subjected to acid immersion tests in 5 laboratories. The life was as shown below:

Material	Copper Content %	Life in Industrial Atmosphere near Pittsburgh Years	Life in Sea Coast Atmosphere Key West Years	Av. Life in 20% H_2SO_4 Hours
Y Open Hearth Steel	0.05	2	2⅔	20
R " " Iron	0.03	2	3⅔	480
V " " Iron	0.05	2⅓	3⅔	325
U " " Iron	0.09	2½	3⅔	950
W Wrought Iron	0.02	3	3⅔	6
N Open Hearth Iron	0.17	3	3⅔	970
S " " Steel	0.05	3¼	3⅔	35
T " " Iron	0.23	Over 5	3⅔	660
K " " Steel	0.27	Over 5	4½	275
C " " Steel	0.22	Over 5	Over 5	235

The acid immersion test does *not* predict atmospheric life. In the field tests of metallic coatings, the failure of galvanized sheets appears to be the inverse of the weight of coating. This test is still in the early stages. 26 pages of tables of data are given on exposure tests of coated and plated articles, like nipples, conduit, angles, bolts, wood screws, clamps, window frame sections and miscellaneous hardware, with hot dip Zn, hot dip Al, electric and gas sherardizing, electroplated Zn, Cd, Pb, etc., and some Amaloy and Parkerized coatings, all put on in regular commercial practice. These were exposed in the usual 5 localities differing in atmospheric conditions. The tests have continued for about 2 years, and the heavier coatings of hot dip Zn and Al are in general, still standing up. Many of the thin plated coatings have failed but the test is not yet far enough along for the committee to draw any conclusions. It merely presents the data. The abstractor has tried to figure out the relative performance of electroplated Zn and Cd of equal thickness from the data. The thickness is seldom the same on the two coatings in any one exposure, but where tentative conclusions can be guessed at, there would appear little to choose between the two, at least the alleged superiority of Cd is not at all evident. The same lots of Cd plated articles show better life in sea coast exposure than in industrial atmosphere exposure, on the whole. Parkerized articles in general have very poor life in sea coast exposure, but the coating appears to give at least a brief protection in industrial atmospheres. HWG(4)

Costly Rust of Metal Supply Can Be Prevented If Temperature Is Kept Above Dew Point In Storage Room. JOSEPH GESCHELIN. *Automotive Industries*, Vol. 64, Feb. 1931, pages 256–260.

Dew point temperature and not relative humidity is danger indicator in rusting of iron and steel stocks. Atmospheric corrosion may be eliminated by maintaining surface temperature somewhat above prevailing dew point temperature. Simple heating system with positive circulation throughout the entire stock will suffice. DTR(4)

Corrosion of Various Aluminium Alloys by Means of Salt-Spray and Intermittent Immersion Tester. H. ENDÔ & K. MIYAZAKI. *Kinzoku no Kenkyu*, Japan, Apr. 1931, pages 197–213.

The corrosion of various aluminum alloys such as duralumin, silumin, No. 12, L. 8, K (1.68% Mg, 0.38% Mn, 3.66% Cu, 7.16% Si), Q, Halmin (2.03% Cu, 1.28% Ni, 1.28% Fe), Al-Mg-Mn alloy and others was studied by means of salt-spray and intermittent immersion testers designed by H. Endo. Every test was done in a manner to suit as practical purposes as possible. Pure aluminum, Al-Mg-Mn alloys (1.1 to 1.3% Mg, 0.6 to 2.9% Mn), silumin and Mg-Mn-Si alloy (0.98% Mg, 1.90% Mn, 6.38% Si) were proved to be superior. KT(4)

Rust Protection of Sheet Iron Apparatus During Manufacture. (Rostschutz von Blechapparaten während der Verarbeitung.) A. DIETRICH *Korrosion und Metallschutz*, Vol. 7, Apr. 1931, page 90.

Note on precautions against rusting of fire extinguishers. EF(4)

Corrosion of Non-Ferrous Metals and Alloys. Report of A. S. T. M. Committee B-3. T. S. FULLER, Chairman. *Preprint* No. 19 for June, 1931 meeting, *American Society for Testing Materials*. 2 pages.

The use of the units, milligrams loss per square decimeter per day, and inches penetration per year, is recommended to A. S. T. M. and other corrosion investigators. Progress is being made on the outdoor exposure tests. A sub-committee is studying the behavior of stainless steel in contact with various non-ferrous metals, under corrosion. HWG(4)

Corrosion and Corrosion Protection on Rolled Aluminum Alloys. (Korrosion und Korrosionsschutz von Aluminium-Walzlegierungen.) P. BRENNER. *Zeitschrift für Metallkunde*, Vol. 22, Dec. 1930, pages 420–422.

Discussion of paper with the same title in the October issue. See *Metals & Alloys*, Vol. 2, April 1930, page 78. (4)

Corrosion Resistant Alloys of the Stainless Type in Use and Fabrication. T. H. NELSON (Midvale Co). *Advance paper* for May 1931 meeting, *American Iron & Steel Institute*, 35 pages, 10 tables.

The compositions and mechanical properties of the plain chromium and the chromium-silicon steels are given, and their behavior on heating described. Carbide precipitation with consequent local impoverishment in chromium is described in relation to 18–8, and experimental evidence offered to substantiate the theory of impoverishment. To prevent reversion from the austenitic state due to impoverishment, it is logical to increase the chromium content. The danger is much less serious in 25% Cr, 10% Ni than in 18% Cr, 8% Ni, especially in welded structures to resist drastic corrosive conditions. Corrosive attack in the chemical industries may be of various types. In order to show how to select an alloy for a given chemical service, the behaviors of the pure metals Fe, Ni and Cr in HNO_3, HCl and H_2SO_4, and that of alloys with about 0.10% C and 18%, 24%, 34%, 43% Cr, with 10% Ni, 18% Cr; 10% Ni, 24% Cr; 19% Ni, 24% Cr; 24% Ni, 10% Cr and 21% Ni, 10% Cr, 4% Cu in 5% solutions of each of the 3 acids at 110° F. are given. In HNO_3, nickel does not materially aid in corrosion resistance, but it may help in fabrication or welding. In the oil industry, the addition of nickel has been found to reduce embrittlement at 800–950° F. In the paper pulp industry, the straight Cr alloys are not satisfactory as to corrosion resistance. Nickel is necessary, but the Cr content must be higher than the Ni content. The author advocates viewing corrosion resistance from the point of view of iron content and finds that, in general, if an alloy of 75% Fe, 25% Cr will serve, so will one of 20% Cr, and 5% Ni, or of 15% Cr, 10% Ni. Or, if an alloy of 65% Fe, 35% Ni behaves well, so will one of 25% Ni, 10% Cr or 20% Ni, 15% Cr. For any given corrosive service, either Cr or Ni should predominate, but as long as the one demanded by the corrosive conditions does predominate, there is a wide latitude in the ratio of Ni and Cr, the Fe remaining constant. Thus, the corrosion resistance needed may be retained, and the mechanical properties and workability of the alloy varied to meet the other conditions imposed. Comparison of alloys might well be made on the basis of iron content. A minimum of Cr or Ni, or Ni + Cr is needed to combat a given set of corrosive conditions. The ability to alter the Ni:Cr ratio and still preserve corrosion resistance helps in choosing an alloy for castings, as some compositions cast easier than others. Castings should be made from alloys that will cast well, not necessarily from those alloys that are preferable in wrought form. A higher Ni, higher Cr, higher C alloy is better from the foundryman's point of view. These corrosion principles can probably be adapted to high temperature corrosion, e. g., in SO_2 gas, present in many furnaces, an alloy in which Cr predominates over Ni is much superior to the reverse. Laboratory corrosion tests in simple solutions are useful only when they exactly reflect service conditions. For service in a complex solution, extrapolation from tests in simple solutions is often entirely erroneous. Tungsten is useful in Ni-Cr-Fe alloys, not only for heat resistance uses, but also, to resist erosion. HWG(4)

Influence of Arsenic on the Dezincing of Brass. (Einfluss des Arsens auf die Entzinkung des Messings.) GEORG MASING. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 35–56.

Two typically different kinds of corrosion can be distinguished in brass. The one is the general corrosion by which the brass as a whole is attacked either in spots or all over the surface. The second type of corrosion is often more dreaded, but theoretically more interesting: the dezincing, which consists in the gradual conversion of the brass into porous copper. It has been found that an important condition of dezincing is insufficient oxygen. The reduction of dissolved copper into metal is proportional to the amount of oxygen present. New tests have corroborated the experiments of Bengough and May in concluding that an addition of traces of arsenic to brass prevents dezincing entirely. This effect increases with an increase of 0.01–0.08% in the amount of As. The electro-chemical aspect of this corrosion is discussed and test results are described. 26 references are cited. See also "On the Dezincification of Brass," *Metals & Alloys*, Vol. 2, June 1931, page 118. Ha(4)

Protection of Tubing in Refrigerating Machines. (Rohrleitungsschutz für Kühlmaschinen.) MERZ. *Korrosion und Metallschutz*, Vol. 7, Mar. 1931, pages 61–62.

Material of pipes, operating scheme, requirements in regard to insulation and corrosion stability, prevention of corrosion attack. EF(4)

On the Corrosion of Molybdenum and Tungsten. (Ueber die Korrosion des Molybdäns und Wolframs.) S. L. MALOWAN. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 69–70.

After reviewing previous publications on the subject, the author presents his own investigations in which the corrosion attack in H_2O, distilled H_2O, KOH, NH_3, HCl and H_2SO_4 was determined colorimetrically. The corrosion resistance of tungsten was found to be remarkably superior to that corrosion stability of molybdenum. EF(4)

Corrosion of Aluminum Casting Alloys. (Korrosion von Aluminium-Gusslegierungen.) W. KRÖNIG. *Korrosion und Metallschutz*, Vol. 7, May 1931, pages 104–108.

Various Al casting alloys were tested for physical properties microstructure and corrosion resistance to sea-water. Alloys containing Cu as a principal addition displayed a poor corrosion resistance and in most cases showed the phenomenon of intercrystalline corrosion. Alloys with an addition of Mg and Mn proved to be superior to Cu bearing alloys. The Mg content, however, should not exceed 7 or 8% otherwise an interdendritic corrosion attack takes place. The writer strongly recommends an addition of Mn up to 1–1.5% which represents the maximum percentage due to the effective changes in physicals. Alloying Sb to Mg-Mn-Al alloys results in a further improvement of the highly anti-corrosive properties of these alloys. EF(4)

Behavior of Nitrided Special Steels against Copper Sulphate Solution. (Verhalten nitrierter Sonderstähle gegen Kupfersulfatlösungen.) O. NIEZOLDI. *Korrosion und Metallschutz*, Vol. 7, Mar. 1931, pages 53–54.

Paper deals with Fry's etching reagent and corrosion tests on nitrided steels, which did not prove to be stable in copper sulphate solutions. EF(4)

The Effect of Ammonium Chloride upon Metals in Industry. (Ueber die Wirkung des Salmiakes in der Metallindustrie.) GEORGE BUEHNER. *Oberflächentechnik*, Vol. 8, Feb. 3, 1931, page 21.

According to the investigations of K. A. Hoffmann, the ammonium chloride acts as ammonium acid and its attack upon metals must not be attributed to the dissociated HCl, as was hitherto taken for granted. This is verified by the ensuing facts. The dry ammonium chloride attacks the metals more effectively than dry HCl. The action of dry ammonium chloride on metals is accompanied by a more violent development of hydrogen than in the case of HCl. The reaction proceeds according to the following equation: $Me + NH_4Cl = NH_3MeCl + H$. Copper is more readily attacked by NH_4Cl than the less noble nickel. At elevated temperatures, the ammonium complex is more stable than HCl and, therefore, the rate of reaction is increased with rising temperature. ER(4)

Steamship Boiler Corrosion and Its Prevention by Improvement of the Boiler Water. (Die Korrosion in Schiffskesseln und ihre Bekämpfung durch Speisewasserpflege.) H. JANSSEN. *Korrosion und Metallschutz*, Vol. 7, May 1931, pages 108–111.

Takes up the prevention of boiler corrosion by purifying the boiler water and considers the main reactions and phenomena accounting for the corrosion of steamship boilers. Emphasizes former investigations of Tillmanns and Klarmann, Splitgerber, Parr and Straub. The paper was presented before the Reichsausschuss für Metallschutz, Kiel, 1930. EF(4)

Address and Report on Corrosion Papers of the Reichsausschuss für Metallschutz. (Begrüssungsansprache und Bericht über Korrosionsarbeiten des "Reichsausschusses für Metallschutz.") E. MAASS. *Korrosion und Metallschutz*, Vol. 7, May 1931, pages 97–104.

Lecture at the General Meeting of the Reichsausschuss für Metallschutz, Kiel, 1930. EF(4)

On the Corrosion Resistance of Copper Bearing Steels. (Ueber den Korrosionswiderstand gekupferter Baustähle.) W. MARZAHL & A. PUSCH. *Korrosion und Metallschutz*, Vol. 7, Feb. 1931, pages 34–39. 11 references.

Various copper bearing steels low in C, Si, Mn, Cr were submitted to corrosion tests in the laboratory and in the free atmosphere. The corrosion attack was studied by determination of the loss in weight and of the physical properties. The corrosion media applied in the laboratory were H_2SO_4, HCl, HCOOH, KOH, NaCl and H_2O. Both sets of experiments clearly proved the superiority of copper bearing steels in regard to corrosion resistance and thus fully confirmed recent results of other investigators along those lines. EF(4)

Influence of Stress on Corrosion. D. J. MCADAMS, JR. (Naval Engineering Experiment Station.) *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 417, 1931, 39 pages.

A continuation of the study of "corrosion-fatigue." The materials reported are Cr-Ni steel, Cr-V steel, stainless iron, Ni, Al bronze, Cu-Ni-Si alloy, Muntz metal, and nitralloy. Each experiment was in 2 stages, (1) corrosion with or without cyclic stress, and (2) a fatigue stage. The lowering of the endurance limit due to the corrosion stage was used as a measure of the "damage" due to corrosion. The results are plotted in the form of several different types of diagrams. Intercrystalline failure under stress is probably due to corrosion pitting. The conditions favoring such pitting are (1) high stress, (2) low cycle frequency, (3) slight intensity of corrosion and (4) very little accummulation of corrosion products. Contains 15 references. JLG(4)

Testing of Metals and Metal Alloys for Their Resistance to the Action of Salt Solutions. (Prüfung von Metallen und Metalllegierungen auf ihre Widerstandsfähigkeit gegen Einwirkung von Salzlaugen.) E. MAASS & W. WIEDERHOLT. (Chemisch-Technische Reichsanstalt.) *Korrosion und Metallschutz*, Vol. 6, Oct. 1930, pages 218–223; Nov. 1930, pages 241–250; Dec. 1930, pages 265–277.

The first installment represents a systematic research on the corrosion resistance of the following materials: Fe with 0.05% C and 0.08% C, electrolytic Cu, brass with 72.5% Cu, pure aluminum containing 0.22% Si and 0.27% Fe, aluminum alloy containing 3% Mn, 2.5% Mg, 0.5% Sb. The corrosion media are solutions of chlorides and sulphates of Na, K and Mg, i. e. Sylvinit, Carnallit, Glauber's salt and Bitter-salt. The following factors, which exert an influence upon the corrosion attack, were studied: degree of submersion (completely and partly), access of air, addition of oxygen, stirring of solution and temperature. The degree of corrosion attack was determined by weighing and by visual examination. Prevention of the access of air decreases the corrosion (0.6), while an increase by the following rates was noted: passing of oxygen: 2.5, stirring: 5.4, heating to 95–100° C.: 8.6. The second part refers to the influence of solid salts upon some 40 materials as Ni, Ni-Cu, Ni-Fe-Cr, electrolytic Cu, bronze, brass, 20/7 Ni-Cr-steel, various steel sheets, aluminum metal and one Al-alloy. Compositions are listed in a table. Length of testing time: one year. Salts used: potassium salts as mentioned above. Two sets of tests were carried out: (*a*) in a closed box filled with a moist atmosphere, (*b*) in a room with the access of the natural atmosphere varying in moisture. The test pieces were covered to a depth of 1 or 2 cm. with the various salts. The original paper must be consulted for the details of the 400 statements given. It might be mentioned that none of the materials tested proved to be absolutely corrosion resistant, and even the Cr-Ni steels were pitted, while a uniform and heavy corrosion attack was found to take place on the plain iron test pieces. Ni and to a smaller extent Ni-alloys, also displayed a fair corrosion stability, which is suspected to be lowered by Fe in the Ni-Fe-Cr alloys. Cu and bronze turned out favorably, too, and a pronounced difference was noted between α and β brass. Al was also locally attacked. The third part deals with solutions of the potassium salts. The testing conditions were as follows: (1) strips were suspended by a thread in a vessel closed by a ground-in stopper, (2) access of air and strips only partly submerged, in order to study the boundary line air/liquid, 250 cm.^{3}, (3) strips completely submerged, 300 cm.^{3}, (4) same as under (1) except addition of oxygen: 2–3 bubbles per min., (5) testing temperature: 90° C. automatically controlled, 400 cm.^{3}. Tests of one week duration and 1–4 months for conditions outlined under (1)–(4). Result of visual examination is given in numerous tables and losses in weight are graphically presented. Includes 5 illustrations and 14 tables. EF(4)

The Chemical Treatment of Metals and Alloys to Increase Their Corrosion Resistance. (Die Chemische Behandlung der Metalle und Legierungen zur Erhöhung der Korrosionsbeständigkeit.) E. COURNOT. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 205.

Summarizes a paper presented before the International Congress of Mining, Metallurgy and Applied Geology, Liege, 1930. EF(4)

Radiators of Acid-Proof and Heat-Proof Materials. (Radiatoren aus säure- und hitzebeständigen Werkstoffen.) H. BINDER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Apr. 11, 1931, pages 465–466.

To avoid expensive tubes of high grade alloyed steels, radiators are made of sheets, which permits a greater flexibility to connect the individual parts of the radiator in parallel or series according to pressure. Chrome-nickel steels, all high heat-proof steels and sichromal, Monel metal and pure nickel can be used successfully as material for such radiators. In cases where acid-proof materials must be used, these materials are, in the end, cheaper than the usual common metals which require frequent renewal. Ha(4)

Recent Progress in Pipe Protection. HENRY W. HOUGH. *American Gas Journal*, Vol. 134, Apr. 1931, pages 40–42.

Reviews development of use of various methods and apparatus used in coating pipes. MAB(4)

A Laboratory Study of the Atmospheric Corrosion of Metals. Part 1. The Corrosion of Copper in Certain Synthetic Atmospheres, with Particular Reference to the Influence of Suphur Dioxide in Air of Various Relative Humidities. W. H. J. VERNON. *Transactions Faraday Society*, Vol. 27, June 1931, pages 255–277.

Experiments showed that copper changed very little in weight when in desiccated or water saturated purified air and in desiccated air containing as high as 10% SO_2. With the introduction of water vapor, attack of copper occurs in SO_2 atmospheres. There tends to be a minimum in rate of corrosion when the SO_2 content of air is 1%, the reaction product being normal copper sulphate. In atmospheres containing less than 1% SO_2 the copper sulphate is associated with excess base; if more than 1% SO_2 is present, there is excess sulphuric acid in the corrosion products. There exists a critical humidity between 63% and 75%, below which relative humidity has little effect on corrosion, and above which it has an enormous effect. CO_2 has little effect on corrosion in the presence of SO_2. In a humid atmosphere containing SO_2 the corrosion process is controlled by the catalytic oxidation of the SO_2, the surface condition of the metal affecting the corrosion rate. If the atmosphere contains H_2S, the corrosion process is controlled by gaseous diffusion through an initially formed film, the surface condition having no effect. Contains bibliography. PRK(4)

Rust and Rust Prevention. G. SODERBERG. *Monthly Review American Electroplaters' Society*, Vol. 18, May 1931, pages 15–28.

The origin of rusting as a process, in which first ferric oxide is formed and which is then further oxidized, is discussed in general and the influence of air and moisture in this corrosion is considered. The prevention of rusting by coating requires the greatest care because the envelope must be resistant toward chemicals and also against mechanical handling. The tendency of various metals to go into solution is described and the means of obtaining a rust-proof coating by proper treating of the articles before plating are discussed. Ha(4)

Short-Time Corrosion Tests. (Korrosionskurzprüfungen.) K. TAUSSIG. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Apr. 1931, pages 107–108.

Discusses previous methods for corrosion testing, the necessity for greatly decreasing the length of the test, and the methods used by Tödt, by Duffek, and by Duffek and Liebreich. MAB(4)

Accelerated Cracking of Mild Steel (Boiler Plate) under Repeated Bending. WALTER ROSENHAIN & A. J. MURPHY (National Physical Laboratory). *Iron & Steel Institute, Advance Copy* No. 16, May, 1931, 20 pages.

It has been observed that a type of failure occurs in boilers that differs both from the intercrystalline cracking occurring in the vicinity of rivet holes and from the action of the better known "fatigue." The failure occurs in parts that have probably been plastically deformed through a comparatively small number of cycles. In order to determine the effect of corrosive media on parts subjected to plastic deformation strips of boiler plate were bent in first one direction and then the other. The time between bends was usually 24 hours, but in some tests it was 5 min., 1 hr., or 48 hr. Failure was judged by the first evidence of cracking and by complete fracture. The number of bends to fracture varied from 25 to 41. Visible cracking and breakage were accelerated by tap water and brine. NaOH solution did not accelerate failure. The samples were usually bent in the solution and kept immersed during the rest period. No evidence of intercrystalline attack was observed on microscopic examination. Other experiments are in progress. Contains 3 references. JLG(4)

Corrosion and Corrosion Protection of Steel. (Korrosion und Korrosionsschutz von Stahl.) E. H. SCHULZ. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 179–194.

Summarizes the advantages of copper-bearing steels. HWG(4)

Novel Corrosion Resistant Protective Coatings for Iron and Steel Objects. (Neuartige korrosionshemmende Schutzüberzüge für Eisen- und Stahlwerkstücke.) H. REININGER. *Automobiltechnische Zeitschrift*, Vol. 34, Jan. 20, 1931, pages 27–29.

The production and texture of novel corrosion resistant coatings are described. Of these, the citoxide browning process is less known to American craftsmen. This process was invented by Dr. Uecker; by it, steel objects, after being immersed in a boiling aqueous solution of an oxidizing organic salt for 5–20 min., are covered with a tenaciously adhering ferrous-ferric oxide coating. The latter may fully compete with parkerized coating, except that it is more readily scratched through. The alumetizing process employed for producing heat resistant coatings is carried out in the following manner: The objects involved are coated with aluminum by a metal spray method. Then the coating is covered with soft flux and heated up to 1000° C. The microscopic examination discloses that in this way a continuous coherent coating is produced. Finally, a method is described for detection of uniformity of aluminum coating. The coated strip is polished without allowing it to cool; the display of blue color is observed, which does not extend to alumetized part of steel strip. ER(4)

Protective Coatings as Produced by Treating the Steels with Phosphates and Painting. (Rostschutz durch Phosphatbehandlung Phosphatierung des Eisens und Anstreich.) E. RACKWITZ. *Oberflächentechnik*, Vol. 8, Mar. 3, 1931, pages 53–56.

The resistance to corrosion of protective coatings on steel sheets as produced by Parker's and Bonderite process is increased still more by additional lacquering, oiling, etc. The author's tests show definitely that the painting of Parkerized sheets not only improves their surface appearance, but renders them more scratch-resistant, imparting to the protective coating also the property of adhering more tenaciously to the surface of steel. The lacquering of Parkerized sheets renders them also resistant to sea water corrosion attack. ER(4)

The Relation of the Moisture in Rust to the Critical Corrosion Humidity. W. S. PATTERSON & L. HEBBS. *Transactions Faraday Society*, Vol. 27, June 1931, pages 277–283.

Assuming that iron rust has a gel structure, the marked effect that rust has in accelerating corrosion can be explained. In humid atmospheres less than 40% saturated, water that is present in the rust is strongly adsorbed by the gel and is held by considerable force such that it is not free to further corrosion. If the humidity is above this critical humidity the gel fills with water and the forces that hold the water are lessened at the same time. Though there is but a small increase in the moisture content of the rust at the critical humidity, a much larger amount becomes available to further corrosion. Contains 9 references. PRK(4)

Chromium Cast Steels Resist Heat and Corrosion. H. D. PHILLIPS. *Foundry*, Vol. 59, Jan. 1, 1931, pages 65–69.

Corrosion-resistant metals usually fall into one of the following classes: (1) ferrites with little C; (2) martensite, non-malleable, being used after hardening; (3) austenite, solid solution alloys of Fe, Ni, Cr, C and Si. Steel may be strengthened by one or more of the alloying elements but the C content must be regulated. Cr in raising critical temperature necessitates higher temperature to relieve working strains. Ni dissolves in ferrite and increases hardness and strength without loss of ductility. When Ni and Cr are present together the good properties of each are enhanced by the other. Tabulates the analysis and physical properties of some alloy steels. Main source of trouble in feeding alloy steels in mold lies in the low heat conductivity as compared to ordinary steel. Cleaning alloy steel castings follows to a large extent the usual steel foundry practice. Martensitic Cr steel is more resistant to corrosion than one with pearlitic structure. VSP(4)

The Constitution of Scale. L. B. PFEIL. *Iron & Steel Institute, Advance Copy* No. 13, May 1931, 19 pages.

The portion of the Fe-O diagram from 70 to 78% Fe was studied by thermal and microscopic methods. Iron oxide was prepared by heating electrolytic iron in air, and samples of desired oxygen content were prepared by heating mixtures of high and low O-content oxides. An equilibrium diagram for the portion of the system studied is given. On slow cooling the ferrous phase decomposes into Fe and Fe_3O_4 at 575° C. The ferrous phase does not include the composition given by the formula FeO; its high iron limit is placed at 76.9% at all temperatures above 575° C., and its low iron limit varies from this composition at 575° C. to 75% Fe at the solidus. Under equilibrium conditions at room temperatures the components present are Fe + Fe_3O_4, Fe_3O_4, or Fe_3O_4 + Fe_2O_3. The outer layer of scale consists of Fe_2O_3, the middle layer of Fe_3O_4, and the inner layer of the decomposed ferrous phase. The inner layer is weak and brittle. In alloy steels the structure of the scale varies with the alloying element. Contains 12 references. JLG(4)

The Corrosion of the Tin-Plate Container by Food Products. T. H. MORRIS & J. M. BRYAN. Department of Scientific & Industrial Research, Food Investigation, Special Report No. 40, 1931. 29 figures, 73 references. Published by H. M. Stationery Office, London. Price 1 s. 6 d.

The problem of the corrosion of tin cans is characterized as the most fundamental with which the industry is confronted.

Lacquered cans give more trouble than unlacquered ones. The alleged relative immunity from corrosion troubles in England is not due to better lacquer or better tin plate, but to the lower temperatures and the type of fruits packed. Double-lacquering does not give immunity. Protective coatings are still imperfect. Glass and aluminum containers have their places, but there appears to be no effective substitute for the tin plate for many types of canning; so its corrosion problem has to be tackled.

The electrolytic theory, the effect of differential aeration, of pH, of depolarizers, and the solubility of tin in organic acids are briefly reviewed. The amount of tin in the foodstuffs, the effect of oxygen, the behavior of the Sn-Fe couple, and the effect of inhibitors are discussed from data in the literature. The effect of an inhibitor is due to adsorption.

Experimental work on corrosion in citric acid indicated that Armco iron was corroded only about half as fast as a 0.07% C, 0.38% Mn steel. If oxide films are removed, cold rolled steel corrodes more slowly in citric acid than hot rolled or annealed. In highly acid solutions oxygen has little effect; in weakly acid (pH 5) it accelerates corrosion greatly. Corrosion of tin is very rapid in presence of ferric citrate, or in the presence of iron and oxygen together.

Experimental work on the Sn-Fe couple showed total corrosion to decrease with increasing acidity, due to the greatly increased attack on the tin. Hydrogen evolution comes from the iron surface, not from the tin. The corrosion of the iron is decreased by contact with tin, while that of the tin is increased by the contact, but the total corrosion is much less than with iron in the absence of tin.

Iron is critically anodic to tin but soon becomes cathodic.

Some very pure sugars, which, however, contained traces of sulphide or sulphite, accelerated the corrosion of the steel, but some impure sugars acted as moderately effective inhibitors. Beet sugar will probably prove of greater value in canning than cane sugar. Sulphur compounds are harmful when acidity is high, but may be beneficial at low acidities. Gelatin appears to be a useful inhibitor at high acidities, but has no effect at low ones.

Lacquering is helpful in avoiding discoloration, due to combination of some coloring matters with tin, or to the formation of tin sulphide. Discoloration by iron sulphide is discussed.

Addition of citric acid to fruits of low acidity is helpful. Cherries in lacquered cans without citric acid produced 65 to 75% hydrogen swells in six to nine months, but when 0.3% citric acid was added the swells dropped to 0 to 5%. Care should be taken to use sugar free from sulphur. Use of beet sugar or of inhibitors of the agar type is suggested.—H. W. Gillett (4) B-

Corrosion Prevention. LESSITER C. MILBURN. *S. A. E. Journal*, Vol. 29, Aug. 1931, pages 148–157.

Means for protecting aluminum from corrosion is the principal topic discussed by the author. In this connection the theory of corrosion is analyzed and various protective coatings, such as paints, oils and greases, and the metallic, chemical and electrochemical types are commented on. Corrosion prevention, in the opinion of the author, is an obligation that rests primarily upon the aircraft manufacturer, who should provide a complete system of corrosion protection, either by design or manufacturing processes, which will be effective for several years and also supply a foundation on which the operator can overhaul the aircraft at the minimum expense. The German methods of protection against corrosion, as described by one of the discussers, do not require any heat-treatment of the metal by the manufacturer, the material being used as it comes from the mill and the sections being drawn through a set of rolls rather than through dies under tension. When heat-treating rivets to prevent corrosion, as outlined by another discusser, they should be quenched quickly. Proper heat-treatment of the metal, its correct preparation for painting and securing good adherence of the paint are necessary. The results obtained from Alclad metal in service are commented upon with satisfaction. Other topics brought out in the discussion include the possibility of rustless steel replacing duralumin; the use of zinc as a corrosion preventive in aircraft construction, the same as this metal is used in ship-building; and data on some of the new foreign alloys that have recently been developed for use in aircraft construction. WAT(4)

The Outdoor Corrosion of Zinc and the Effect of Rainfall and Atmospheric Pollution. W. S. PATTERSON. *Journal Society Chemical Industry*, Vol. 50, Apr. 3, 1931, pages 120–123T.

Specimens of pure Zn and Zn alloys were exposed to the atmosphere in the Clerkenwell area of London for several months. The rainfall was measured, corrosions rates determined by the loss in weight and the protective properties of the corrosion products determined. The alloys consisted of pure Zn containing 1.62% Sb, 1.90% Fe and 1.03% Pb respectively. Corrosion was most rapid in the winter months when pollution was greatest. The initial attack on Zn was acidic in character. The Zn-Sb alloy was most attacked and the Zn-Pb alloy the least. A certain amount of protection was obtained by the presence of corrosion products. The ultimate corrosion rate decreased due to the formation of basic salts and depended primarily upon the solubility of the corrosion products in polluted rain containing S compounds falling during the winter months. WHB(4)

The Effect of Artificial Aging upon the Resistance of Super-Duralumin to Corrosion by Sea-Water. K. L. MEISSNER. *Engineering*, Vol. 131, Mar. 20, 1931, pages 406–408.

Condensed from paper read before the Institute of Metals, Mar. 12, 1931. See *Metals & Alloys*, Vol. 2, July 1931, page 128. LFM(4)

A New Method for the Determination of Corrosion. (Ueber einen neuen Weg zur Korrosionsprüfung.) L. W. HAASE. *Chemische Fabrik*, Vol. 4, Apr. 15, 1931, pages 169–170; Apr. 22, 1931, pages 184–185.

Contains 4 references. The apparatus described is especially useful for determining the action of different kinds of water on water pipes. The constant renewal of water and control of oxygen is important in such tests. The water flows by gravity first into one beaker then overflows into another beaker through which oxygen is bubbled. A constant head gives a constant flow of 4–6 cc. per minute. This rate was found to give accurate results. Platinum electrodes are suspended in the beakers and the small electric current set up across them by the flow of the water is measured. It was found that the strength of this current depends on the corroding effect of the water. By using a slow rate of flow a protective coat is formed quickly and results can be obtained in 24 hours. Solutions differing little in chemical composition can be accurately tested. Results check with those obtained by other methods. CEM(4)

Deposition of Black Copper Oxide on Brass. HENRY L. KELLNER & HARRY A. CURTIS. *Industrial & Engineering Chemistry*, Vol. 22, Dec. 1930, pages 1321–1324.

The "black-bronzing" of brass is accomplished commercially by dipping the cleaned brass in a bath composed of copper carbonate and aqua ammonia. The bath corrodes the brass surface, and the black deposit, which consists of partially hydrated cupric oxide, is laid down over the roughened surface. The seemingly black and continuous deposit is curiously translucent when viewed under the microscope. MEH(4)

The Essential Factors of the Mechanism of Corrosion of Iron and Steel. T. FUJIHARA. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 25–38.

Includes discussion. Very sketchy tests are described, and about the usual conclusions drawn. Among the conclusions is that "dissolved iron, the soluble hydroxide of which is alkaline in nature, protects the metal," until neutralized by carbonic acid. HWG(4)

The Resistance of Copper-Nickel Steels to Sea Action. J. NEWTON FRIEND. *Iron & Steel Institute, Advance Copy* No. 7, 1931, 5 pages.

Steels containing as much as 3.8% Ni and 9.8% Cu with 0.2% C were melted in crucibles, cast and forged into square bars. The tensile properties are given. The bars were exposed for 2 years at half tide, and the effect of corrosion determined by appearance and loss of weight. Forged bars suffered more than annealed bars. The addition of Cu up to 3.7% increased the resistance of the steels to the alternate wet and dry conditions. The most resistant steel contained 1.16% Cu and 3.75% Ni. The effect of Cu plus Ni on microstructure is discussed. Ni greatly refines the structure as cast, but Cu does not. Contains 3 references. JLG(4)

Visual Inspection of A. G. A. Coatings. S. EWING. *American Gas Association Monthly*, Vol. 13, July 1931, pages 306–308.

471 pipe specimens with various types of coatings supposed to prevent corrosion in soil, buried in 9 locations for nine to twelve months were examined as to chemical attack upon the coating, mechanical attack by soil stresses, and condition of the pipe itself. The ratings are given in detail with symbols referring back to the descriptions of the coatings given in the A.G.A. Monthly for June 1930, page 269, so those interested may have the facts, but no conclusions are drawn. HWG(4)

The Action of Lime-Water on Aluminum. (Die Einwirkung von Kalkwasser auf Aluminiummetall.) GUNNAR ASSARSSON. *Zeitschrift für anorganische Chemie*, Vol. 191, 1930, pages 333–339.

The dissolution of commercial aluminum in lime-water varying in concentration between 0.045 and 0.125% calcium oxide was investigated at 0°, 17°, 22°, 40°, 50°, 65° and 90° C. The nature of the reaction products and their crystal form were determined. According to the concentration of the ime-water and the temperature, the following compounds or mixtures of them are formed: Al_2O_3, $4CaO,12H_2O$; Al_2O_3, $3CaO$, $12H_2O$; and Al_2O_3, $3CaO$, $6H_2O$. (4)

Oxygen Promotes Corrosion of Iron in Two Ways. H. ENDO & S. KANAZAWA. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 251–260, 17 references, 8 figures. In English.

Includes discussion. Oxygen promotes solution of iron in the first stage of corrosion and by oxidation of hydrogen and precipitation of ferrous ions, also promotes it in the second stage. HWG(4)

The Mechanism of the Suppression of Corrosion Velocity by Colloids. (Ueber den Mechanismus der Hemmung der Korrosionsgeschwindigkeit durch kolloide Stoffe.) W. BECK & F. v. HESSERT. *Zeitschrift für Electrochemie*, Vol. 37, Jan. 1931, pages 11–20.

The decrease in corrosion velocity of Fe in H_2O or strong acid solutions is due to the presence of hydrophilic colloids, and is dependent upon the type as well as the concentration of added colloid. The authors suggest the possibility of the formation of coagulation layers upon the surface of the metal, due to the action of the Fe ions upon the negatively charged particles of the hydrophilic colloid. The colloidal materials studied were agar, starch, silicic acid and gelatine, and the metals Armco, electrolytic, carbonyl and pure Fe. (4)

Corrosion Resistance of Aircraft Bracing Cables with Different End-Connections. M. ABRAHAM. *Wire & Wire Products*, Vol. 6, July 1931, pages 283–289.

Cables made from hot dipped zinc coated, and of cadmium plated carbon steel, and of uncoated steel of the 18 Cr, 8 Ni type, provided with sleeve fittings, splices, or soldered terminals, were exposed to salt spray test for 120 days and tested. The cadmium plated wires pulled out of the sleeve fittings. The others ran from no loss up to a loss of 7% of their initial strength. The zinc coated specimens did not pull out of the sleeves. The wire lost 10 to 15% of its strength. Coating with two coats of aluminum paint reduced the loss from 0 to 6%. Coating with linseed oil or a bituminous coating gave losses of 15 to 33%. The stainless wire lost from nothing up to 4% of its strength except when soldered with a $ZnCl_2$-HCl flux and failing to neutralize the flux remaining on the wire, which in one case brought about a loss of 13%. Splicing reduces the strength. From the strength and weight points of view, the soldered terminal is preferred. Preference is expressed for a cadmium coated cable with soldered connections and two coats of aluminum paint. HWG(4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Structural Analogies of Binary Alloys of the Transition Elements with Zinc, Cadmium, and Aluminum. (Strukturanalogien der binären Legierungen von Uebergangselementen mit Zn, Cd and Al.) W. EKMAN. *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 12, Feb. 1931, pages 57–58.

The X-ray diagrams of binary alloys of zinc with iron, cobalt, nickel, rhodium, palladium, and platinum and of alloys of nickel with cadmium show that in all these systems a phase with the structure of γ-brass is capable of existence. In each case the region of homogeneity extends on either side of a composition corresponding with an atomic ratio of the transition element to the other component of 5:21. If the transition elements are assumed to possess zero valency, this composition represents a ratio of valency electrons to atoms of 21:13 (Westgren and Phragmen, A., 1929, 987). The iron-zinc phase is homogeneous between 19 and 23 atomic percent iron, the cobalt-zinc phase between 15 and 22 atomic percent cobalt and the nickel–zinc phase between 15 and 19 percent nickel. In the system cobalt–zinc a phase having the structure of β-manganese may be present and in the system cobalt–aluminum a phase similar to β-brass, the region of homogeneity of the latter phase including a mixture for which the ratio of valency electrons to atoms is 3:2. The formation of all the above phases from their constituent elements is accompanied by a considerable diminution in volume. (5a)

Virtual Images in Metallurgical Microscopy, Caused by Reflection in the Polished Surface. (Vid metallmikroskopi genom spegling uppträdende skenbilder.) C. BENEDICKS & H. LÖFQUIST. *Jernkontorets Annaler*, Vol. 115, June 1931, pages 310–313.

It is shown that in some cases two images of the same particle may be obtained by focussing above and below the surface under observation. This is due to reflection of the particle lying above the surface into the highly polished surface. The direct photograph gives the front side of the particle, while the reflection gives the back view. This effect makes it somewhat difficult to determine whether a given particle, for example, a slag inclusion, lies above or below the surface. HCD(5a)

Kinetic Measurement of a Transformation-Reaction in Solid Metals. (Kinetische Messung einer Umwandlungsreaktion in festen Metallen.) W. FRAENKEL & E. WACHSMUTH. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 219–229; 6 figs.

Nature of the Nickel-Chromium Rustless Steels. ROBERT H. ABORN & EDGAR C. BAIN, *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 837–893.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion, six references to previous work and is illustrated by 14 micrographs and numerous diagrams. The effects of nickel, carbon and chromium on the instability of the austenitic state are discussed. The effect of cold work in development of ferrite is discussed. Magnetic measurements, microscopic observations, X-ray analysis, corrosion tests and hardness studies have been made to determine the course of these reactions, knowledge of which is essential to the manufacture and use of these alloys. WLC(5a)

The Equilibrium Diagram of Copper-Tin Alloys. M. HAMASUMI & S. NISHIGORI. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 211–214. In English.

Study of alloys in the region 10 to 40% Sn.

The δ phase is alleged to correspond to Cu_3Sn_8. The η phase corresponds to CuSn and transforms at 675° C. into γ with a linear expansion of 0.56%. There are three eutectoid transformations at 510°, 570°, and 630° C. corresponding to the change of α plus δ to β, δ plus η to ϵ, and β plus η to γ. Also two peritectic transformations at 577° and 625° C., corresponding to the δ to β plus ϵ, and the ϵ to β plus η changes. The transformation of δ and η into ϵ produces a linear expansion of 0.25%. The ϵ phase is indicated by resistance and expansion curves; also by metallographic examination of a quenched 33.6% Sn specimen. HWG(5a)

Equilibrium between Carbon and Its Oxides. (L'equilibre entre le carbone et ses oxydes.) P. E. HENRY. *Annales des Mines*, Series XII, Vol. 19, 1931, pages 5–25.

The work on equilibrium between C and its oxides by O. Boudouard, Read and Wheeler, Lewis and Randall, Schenck and his collaborators is comprehensively and critically reviewed. JDG(5a)

Equilibrium Diagrams of the Aluminum-Manganese, Copper–Manganese and Iron–Manganese Systems. T. ISHIWARA. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 143–155; *Science Reports Tohoku Imperial University*, Vol. 19, 1930, pages 499–519.

In English. Gives the diagrams and brief discussion. Since the diagrams are necessary for understanding of the discussion and the points brought out cannot be briefly abstracted, the original should be consulted. HWG(5a)

Equilibrium Diagram of the Ternary System of Tin, Lead and Antimony. K. IWASÉ & N. AOKI. *Kinzoku no Kenkyu*, May 1931, pages 253–267.

The equilibrium diagram of the ternary system Sn–Pb–Sb was determined by means of total and differential thermal analysis and by microscopic examination of well annealed specimen. The diagram has three non-variant points. The first corresponds to the β to β' transformation of the binary system of antimony and lead which was not discovered by Loebe and Campbell; the second to the eutectic crystallization of α, β and δ from the liquid which was considered by Loebe and Campbell as peritectic; the third to the pericto-eutectic reaction liquid $+ \beta \rightleftarrows \gamma + \delta$. There must be a maximum point in the binary eutectic curve joining the second and the third non-variant point and was found to be 245° at 10% Sb and 10% Sn. KT(5a)

On the Structure and Nature of Troostite. F. F. LUCAS. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 69–92; *Bell System Technical Journal*, Vol. 9, 1930, pages 101–120.

Evidence of high-magnification metallographic study indicates that primary nodular troostite is an aggregate of ferrite and carbide. HWG(5a)

On the Microstructure of Pearlite. M. MIKAMI. *Kinzoku no Kenkyu*, July 1931, pages 350–353.

The present writer investigated whether the dark etched portion of the pearlite is cementite or ferrite by making the model of pearlite and came to the conclusion that the dark portion is not always cementite or ferrite, but in the most cases it is an oblique side of cementite relief. KT(5a)

On the Lowering of Critical Points in Molybdenum Steels. T. MURAKAMI & T. TAKEI. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 39–67; *Science Reports, Tohoku Imperial University*, Vol. 19, 1930, pages 175–207.

In English. Sixty-five alloys ranging from 0 to 70% Mo and 0 to 6% C were studied. The lowering curves are shown. The results do not accord with the theory of Swinden that lowering is due to solution of a molybdenum compound, but rather with the idea that it is a super-cooling effect. See also *Metals & Alloys*, Vol. 1, Nov. 1930, page 844. HWG(5a)

The AMINCO Automatic Metallographic Polishing Machine

Patent Applied for

THIS new machine is based upon a similar one, developed by the U. S. Bureau of Standards' engineers, to effect a standardization of methods employed in polishing specimens for microscopic examination. To their design we have added several improvements of our own and can now supply the machine as pictured above, ready for use in the laboratory. It produces a remarkably high polish, free from pits and "comet-tails", such as occur on specimens that are hand polished and showing perfect formation of inclusions, with practically no rounding-off of edges of the cracks. It accomplishes this automatically, polishing three specimens at the same time, without requiring the constant attention of a high-salaried technician. This new machine will very quickly save many times its cost in any metallurgical laboratory. A bulletin describing it in detail will be sent to you promptly, upon request.

The Solution of Cementite in Carbon Steel and the Influence of Heterogeneity. ERIK WALLDOW. *Engineering*, Vol. 113, Jan. 2, 1931, pages 27–30.

Condensed from paper used before the Iron and Steel Institute, Prague, Czechoslovakia, Sept. 15–20, 1930. See abstract in *Metals & Alloys*, Vol. 2, Jan. 1931, page 4. LFM(5a)

Decomposition of Austenite. H. S. VAN VLEET (Western Electric Co.) & CLAIR UPTHEGROVE (University of Michigan). *Metal Progress*, Vol. 18, Oct. 1930, pages 68–70.

The previously accepted facts on austenite retention and decomposition are summarized. Curves of decrease in density vs. drawing temperature and residual induction times coercive force vs. drawing temperature on quenched magnet steels both show distinct changes of slope at 300°, 525°, and 605° C. Differences between oil, water and 5% NaOH quenched specimens disappear at 300° C. showing that quenching stresses are relieved. The density increase between 300° and 525° C. is due primarily to martensite decomposition, while the practically constant density and magnetic properties between 525° and 600° show that the decomposition of austenite is counterbalancing that of martensite. While liquid air immersion decomposes austenite to martensite (although not completely in the 5.7% W magnet steels investigated) the results are different from those of tempering as shown by hardness tests and magnetic measurements. WHK(5a)

Theory of Arranged Mixed Phases. (Theorie der geordneten Mischphasen.) G. WAGNER & W. SCHOTTKY. *Zeitschrift für physikalische Chemie*, Vol. XI, Dec. 1930, pages 163–210, 35 references.

The problem of this scientific treatise is "to arrive at advanced theoretical deductions concerning the properties of systems with intermediate crystal phases by means of the application of certain pattern-like conceptions." The interest of the metallurgist is attracted by the discussion of the following systems (pages 199–210) 3 uranium-8 oxide (oxygen partial pressure during isothermal decomposition) γ'-phase of the Fe–N system. Fe_4N (equilibrium pressure of the gas phase between NH_3 and H_2) intermetallic compound in the Hg–Zn system (electromotoric forces) intermediate phase in the Au–Hg system (saturation pressure of Hg) and resistance concentration on diagram of the Au–Cu system. Photomicrography with the 365mμ Mercury Arc Line. A. P. H. TRIVELLI & L. V. FOSTER. *Journal of the Optical Society of America*, Vol. 7, Feb. 1931, pages 124–131.

A joint communication from the research laboratories of the Eastman Kodak Company and from the scientific bureau of Bausch and Lomb Optical Company. Without doubt the highest resolution is secured by Kohler's ultra-violet photomicrographic outfit, but micrography with λ365mμ approaching this resolution has the following advantages over Kohler's apparatus: (1) A glass system can be used instead of the expensive quartz system. (2) The light source is a mercury arc lamp with filters, which is much simpler than the spectroscopic outfit used to obtain a high intensity cadmium line. (3) The focusing can be greatly simplified, as will be explained. One of the authors has overcome the difficulties previously experienced with commercial objectives. The arc spectrum of mercury in the near ultra-violet is discussed, as are light sources, objectives, immersion oils, microscopic objects, photographic materials and finally the results, which are illustrated by comparative photomicrographs. The Micro-Mechanical Study of Metals. (Etude Micro-mécanique des Métaux.) P. A. WELIKOFF, N. P. STCHAPOFF & W. F. LORENZ (Institut Scientifique Expérimental des Transports, Moscow). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 328–333, 14 micrographs.

The plastic deformation of small test pieces is examined microscopically in the course of the application of tension or compression. Micrographs and discussion are given of the slip lines in rail steel and in a 0.40 C, 1.0 Cr, 3½ Ni steel. HWG(5a)

Some Physico-Chemical Changes in So-Called Pearlitic Cast Irons. (Sur quelques modifications physico-chimiques des fontes dites perlitiques.) AUGUST LE THOMAS. *Bulletin de l'Association Technique de Fonderie*, Vol. 5, Feb. 1931, pages 46–58.

Physico-chemical phenomena accompanying heating and cooling of cast iron are exceedingly complicated. The use of constitutional diagram can only indicate the general trend of the phenomena because the number of the usual variables is too large and besides the inherent properties of the iron under which are grouped many badly understood characteristics inherent to different heats of the metal have almost as great an influence as the major characteristics. On cooling a typical pearlitic iron to 1150° just above it one obtains a mixture of 57% of liquid containing 4.2% C and a solid solution with about 1.4% C. Just below it the mass is solid and consists of crystals of solid solution and lamellae of graphite. As the solubility of carbon in solid solution is proportional to the temperature the lowering of it is accompanied with precipitation of graphite. It does not last long. At a certain temperature the conditions permitting the stable equilibrium (carbon and silicon content, the rate of cooling, etc.) become ineffective. Until this point the imaginary point of transformation was following a line on equilibrium diagram corresponding to the saturated solution of graphite. Reaching it the solid solution is enabled to cool without any changes in concentration. It now follows a vertical line on the diagram until it reaches the area of the solid solution. During this period the proportion of graphite both primary and secondary and of the solid solution remained the same. Depending on carbon concentration the metal at this point either deposits the excess of carbon along the lines roughly corresponding to the outlines of cells, or, if the temperature of the end of graphitic precipitation was low enough to lead to the formation of a solid solution with less than 0.9% C, to the precipitation of ferrite. An intermediary case is possible when the precipitation point corresponds to 0.9% C. The mechanism of changes produced by heat treatment was given in the previous article (A. Le Thomas, "Les alterations de la fonte aux hautes temperatures," *Bulletin de l'Association Technique de Fonderie*, Sept. 1929). During transformation below A_c a relatively fine mixture of ferrite and graphite is produced depending on the maximum temperature obtained in heating cycle. The final products of it are: graphite of solidification, both primary and secondary; graphite produced by decomposition of cementite, cementite not entirely decomposed; ferrite of the decomposition; pearlite more or less coalesced. Heating the metal above A_c one dissolves both the ferrite and decomposing cementite in the solid solution so that at the end only graphite and solid solution are present. On cooling to room temperature the same mixture as originally is liable to form. Using so-called pearlitic iron and a temperature decidedly above A_c one can see that the graphitization begins at about 1000° above which it is rather pronounced. Cooling does not show any changes corresponding to the solution of the precipitated graphite; though A_r point is well marked. When cooling takes place at the moment of equilibrium of graphite with solid solution it might produce: cementite and pearlite, ferrite and pearlite or only pearlite, which is largely dependent on the speed of cooling. Pearlitic irons produced by annealing of white irons often have a high strength. An iron with 2.8–3.2 C, 1.0–1.4 Si and about 0.7 Mn when cast produces a white iron but after heating to 950°, 1015° and 1070° followed by a furnace cooling has a hardness of 336, 223 and 179 kg./mm.², respectively, while its flexion increases from 0.19 to 0.48 mm. on bars 8 × 10 × 35 mm. Evidence That Metal Is Crystalline. E. E. THUM. *Metal Progress*, Vol. 19, May 1931, pages 75–80.

The author's paper is illustrated with a dozen photographs of dendrites and polyhedral grains structure. Metallographic and X-ray evidence of the crystalline character of metals is presented. WLC(5a)

A Brief Discussion of the Metallography of the Stainless Steels and Irons. EDGAR C. BAIN. *U. S. Steel Quarterly*, Vol. 1, No. 4, 1930, pages 79, 81, 83.

The chromium alloys possess the highest physical properties among the ductile and workable corrosion-resisting metals. This unique behavior extends to inertness in the presence of very active oxidizing environments such as nitric acid. They cannot be used in acid conditions not forming a resistant oxide surface, for instance in hydrochloric acid. The desirability of analyzing the conditions of the application, both as to temperature and as to the chemistry of the environment, cannot be too strongly advised, because then only the best suited metal for the purpose can be selected. This requires the coöperation of user and manufacturer. The carbon effect in the ferritic and austenitic alloys is briefly explained and illustrated by a few micrographs. Ha(5a)

Ghost Lines due to Crystalline Junctures. J. FLETCHER HARPER & HAROLD J. STEIN. *Metal Progress*, Vol. 20, Aug. 1931, pages 75–80.

This article with one which appeared in the July issue form a paper to be presented before the Boston Convention of American Society for Steel Treating, September 1931, and to be published later in greater detail with discussion. The authors discuss ghost lines arising from the segregation at the juncture of the columnar (outer) and the random (core) crystals of an ingot. A 30″ diameter shaft forged from a 48″ ingot was examined. A surface at a diameter of 17″ showed ghost streaks. Radial and tangential tensile and Charpy specimens taken as indicated in a diagram given showed lower ductility, Charpy value and flaws in the fractures while longitudinal test specimens were not affected in their values by this segregation. The occurrence of similar ghosts in two other shafts is described. WLC(5a)

The Sub-Crystalline Structure of Ferrite. C. O. BANNISTER & W. D. JONES (Liverpool University). *Iron & Steel Institute, Advance Copy* No. 2, 1931, 15 pages.

Work on the veining or sub-crystalline structure is reviewed. The structures found in wrought iron were studied, and it was concluded that 3 types of structure existed. Type I is similar to the cored structure associated with solid solutions, and probably represents a P segregation. It was found possible to produce this structure in a steel containing 0.098% P by means of short annealings above Ac_3. Type II consists of a deep veining of the ferrite crystals. Type III is a modification of type II, and its appearance is similar to etching pits. It is produced by the continued etching of material containing the type II structure. Both types II and III are probably manifestations of microscopical or sub-microscopical inclusions. Conditions causing and preventing veining are discussed. Contains 17 references. JLG(5a)

The Influence of Third Metals upon the Constitution of the Brasses. III. The Influence of Tin. (Der Einfluss von dritten Metallen auf die Konstitution der Messinglegierungen. III. Der Einfluss von Zinn.) O. BAUER & M. HANSEN. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 387–391; Dec. 1930, pages 405–411; Vol. 23, Jan. 1931, pages 19–22.

The ternary system Cu–Zn–Sn was studied in the composition range 70 to 50% Cu and 0 to 6% Sn thermally and micrographically. The results are expressed in constitution diagrams for alloys with constant Sn contents, 1.0, 2.0, 3.0 and 5.0%. Previous observations on the freezing ranges were confirmed. It was found that in a certain range the peritectic decomposition, α + melt = β, takes place, analogously to the relations in the Cu–Zn and Cu–Sn systems. The α and β solid solutions in the Cu–Zn and Cu–Sn systems are isomorphous. The peritectic temperature in the Cu–Zn system (905°) is increasingly depressed by the addition of Zn, and this depression is greatest for Cu-rich alloys. It amounts to 25°, 55° and 85° for alloys with 1, 2 and 3% Sn, respectively. The temperatures of the solubility changes and transformations in the solid state were determined by metallographic study on annealed and quenched specimens. The data obtained permit the construction of the full ternary system in the range studied. Falling temperature first results in the precipitation from the β-phase of the α- or the γ-ternary solid solution and then in the simultaneous precipitation of both α- and γ-phases. In one composition region the precipitation results in a complete absorption of the β-phase, that is, $\alpha + \gamma$ eutectoid is formed. The solubility curves bounding the $\alpha + \beta$ field are displaced toward Cu-rich concentrations with increasing Sn content and with rising temperature. The solubility of Sn in β-brass increases rapidly with temperature. At 400° 1.5% Sn is soluble in β-brass, while the α-phase saturated with Zn dissolves only 0.4% Sn at this temperature. More than 0.4 to 1.5% Sn (according to the Cu content) in alloys with 62 to 55% Cu leads the formation of brittle γ crystals besides α and β. The ternary α, β, γ and solid solutions in equilibrium from 400° to room temperature have the following compositions: α = 62.3% Cu, 0.4% Sn, 37.3% Zn; β = 55.0% Cu, 1.5% Sn, 43.5% Zn; γ = about 52% Cu, 8% Sn, 40% Zn. A note is appended giving the Brinell hardness of the ternary alloys investigated. RFM+EF(5a)

Study of High-Chromium, Low-Carbon Steel. ARTHUR PHILLIPS & RALPH W. BAKER. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 894–907.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The first section gives semi-quantitative data on the rate of grain growth in 28% chromium, 0.25% carbon steel. Correlation of factors of time and temperature with grain size are shown graphically. This steel reaches its maximum grain size in comparatively short periods of time at high temperature. The second section gives a microstructural study of 28% chromium steel, carbon 0.07 to 0.26. The gamma free limit is shown to be 0.10% carbon instead of 0.20% carbon as reported by previous investigators. WLC(5a)

Oxygen Containing Structure Elements in Iron-Carbon Alloys. (Om syrehaltiga strukturelement i Täckjarn.) CARL BENEDICKS. *Jernkontorets Annaler*, Vol. 115, Mar. 1931, pages 147–159.

By mixing molten pig iron with about 5% of magnetite, structure elements with a high content of oxygen were obtained, which could be observed microscopically without etching. On the one hand there is observed an oxy-pearlite, structurally identical with the oxy-pearlite discovered by the author in the iron found at Ovifak, Greenland formed by a process of natural reduction. This structure consists of alternating gray and white lamellae, either protruding from the grains of FeO or developed inside the latter. On the other hand there is also observed a solidification structure, containing idiomorphic cementite crystals, austentite with dissolved oxygen (oxy-austenite) and ferrous oxide. This structure seems to correspond to the ternary eutectic oxy-austenite–cementite–ferrous oxide. HCD(5a)

Metastable Equilibrium in Hypereutectoid Iron-Carbon Alloys. A. ALLEN BATES, D. E. LAWSON & H. A. SCHWARTZ. *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 659–672.

A paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The composition of the 2 phases in equilibrium in the metastable system between eutectoid and eutectic temperatures was determined by a planimetric study of 2 binary alloys differing in carbon. While the location of A_{cm} line is confirmed this work does not show the carbide phase above the eutectoid point to agree with the formula Fe_3C. The explanation is believed to be in a solution of γ-iron in the carbide phase. Preliminary observations on the possible solubility of carbon in iron carbide are made. WLC(5a)

Equilibrium Diagram of the Alloys of Calcium and Sodium. (Diagramme de solidification des alliages calcium-sodium.) E. RINCK. *Comptes Rendus*, Vol. 192, June 1, 1931, pages 1378–1381.

Using metals prepared by fractional distillation, the author has obtained a series of alloys of calcium and sodium of which the melting points, etc., have been observed. An equilibrium diagram based on these observations has been prepared—it is characterized by a field of partial miscibility in the liquid state. The concentrations of the conjugate liquid solutions were obtained by determining the isothermals for the reaction $Ca + 2NaCl = 2Na + CaCl_2$. The author stresses the value of this method of attacking the problem of determining the limits of the field of partial miscibility in alloy systems. OWE(5a)

Texture of Drawn Magnesium and Zinc Wires. (Ueber die Textur gezogener Magnesium- und Zinkdrähte.) E. SCHMID & WASSERMANN. *Mitteilungen der deutschem Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 87–89.

The investigations with these 2 hexagonal metals have proved that the crystal arrangement can be a tissue texture, spiral tissue texture and circular tissue texture while in other worked metals only the first one has been observed. Ha(5a)

Structure and Mechanical Properties of Cast Aluminum Alloys. (Structuur en vastheidseigenschappen van gegoten aluminium legeeringen.) P. SCHOENMAKER. *De Gieterij*, Vol. 4, Dec. 1930, pages 193–196.

A discussion of the microstructure and mechanical properties of an alloy containing 3.7% Cu and 7% Zn (a) in the sand-cast, (b) in the chill-cast, (c) in the annealed and (d) in the age-hardened state. Excellent etchings were obtained by polishing the samples with fine alumina and dipping the polished specimens in a very dilute solution of $FeCl_3$ in HCl. Rubbing from time to time with a piece of cotton moistened in the solution brings out the structure. HSvK(5a)

(Study on) Crystal Structure of Cementite. S. SHIMURA. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 223–225; *Proceedings Imperial Academy*, Tokyo, Vol 6, 1930, pages 269–271.

Using manganiferous cementite, and straight cementite (no details of purification given), it was found that Mn did not affect the crystal structure of cementite. The dimensions of the unit cell are given as a, 4.51; b, 5.04; c, 6.73 A. U. HWG(5a)

Alloys. Relation between the Colors and the Microstructures of Some Binary and Ternary Silver Alloys. SHUZO UENO. *Memoirs College of Science Kyoto Imperial University*, Series A, Vol. 13, No. 2, Mar. 1930, pages 141–147.

The relation between colors and micro-structure in some binary and ternary silver alloys is reported in the present paper. Details of arrangements for the experiment were described in the Sexagint, Kyoto, 1930. Curves showing reflection and intensity of reflection are shown for the binary alloys of Al, Ag and the ternary alloys of Al, Ag and Zn. WHB(5a)

Composition Limits of the Alpha-Gamma Loop in the Iron–Tungsten System. W. P. SYKES. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 428, Sept. 1931, 7 pages.

The γ-loop in Fe-W alloys was located by microscopic examination of samples quenched from the critical range. The 2 loops representing the boundaries of the γ-field and the γ-plus α-field extend to approximately 3 and 6.5% W, respectively. 4 references. JLG(5a)

Further Studies on Chromium-Nickel-Iron and Related Alloys. VSEVOLOD N. KRIVOBOK and others. *Preprint, American Society for Steel Treating*, Sept. 1931, 40 pages.

The present investigation deals with the theoretical considerations concerning the Cr-Ni-Fe-C constitutional diagram, with factors influencing the latter, with the so-called "decomposition" or "disintegration" of these alloys. Such decomposition is known to be accompanied by the precipitation of a constituent generally believed to consist of carbides. It is suggested that the precipitated constituent is not necessarily a carbide: in fact, in very low carbon alloys, the precipitated constituent is, undoubtedly, magnetic chromium-nickel ferrite. That is to say, the nature of a separating constituent is dependent upon the carbon content of the alloy. A phase change, from nonmagnetic to magnetic, accompanies decomposition. Whether decomposition precedes phase change or follows it is a matter of conjecture. The alloys were studied by means of magnetic analysis, microscopic observations, and corrosion tests. Alloys of extremely low carbon content, in which no carbide precipitation could take place, are described and shown to be immune from decomposition. When carbon is increased above a certain very small amount, the decomposition process is practically independent of the carbon content, and consequently there is very little reason to aim at the low carbon content in commercial alloys. A large number of Cr-Ni-Fe alloys with the addition of other elements (such as cobalt, molybdenum, silicon, copper) are described from the point of view of their behavior when subjected to decomposition treatment. It was found that the additions of certain elements prevent phase change, but do not suppress precipitation of a constituent, presumably, carbides. It was also shown that, contrary to ordinary Cr-Ni-Fe alloys, such precipitation has but little effect on some of the mechanical properties and resistance to corrosion in standard acid solutions, although the so-called copper sulphate test shows these alloys to be equally susceptible to attack. On the strength of this study, a suggestion is made that copper sulphate tests should be applied with intelligence. Changing the relative amounts of chromium and nickel in the alloy, as for example, using 12% Ni and 12% Cr instead of 18% Cr and 8% Ni, does not improve the alloy from the point of view of decomposition. The resistance to decomposition of alloys with special additions seems to be materially influenced by carbon content. The general indication is that the higher the carbon content, the larger must be the additions of those elements, which have been found to be beneficial. The influence of the treatment which the alloys received previous to the decomposition treatment is fully described. Original quenching temperature of the alloy exercises a very definite influence on decomposition. Alloys of different carbon content of the general "18–8" composition can be divided into three groups, each group with definite magnetic characteristics after decomposition treatment. Numerous curves showing the relationship betweendifferent properties of decomposed alloys are presented. WAT(5a)

Compounds of Copper–Tin and Other Systems. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 19, May 1931, pages 88–89.

A portion of the constitutional diagram Cu-Sn is reproduced and experiments on Cu-Sn compounds are discussed. WLC(5a)

LEITZ-OGRAPH

Your Metal Samples as a guarantee for unfailing and reliable results

LEITZ MICRO-METALLOGRAPH "MM"
(Inverted Microscope with Camera)

Preparing the metal sample in a faultless manner is the first step toward a perfect micro-analysis

The "Guthrie-Leitz" Automatic Polishing Machines, of ONE-, TWO-, and FOUR-Spindle Type, by means of a magnetic holding and oscillation device, produce these results in an automatic manner, eliminating all elements of human equation. These Automatic Polishing Machines represent a distinct labor saving device, thereby repaying their cost in a short time.

As the next step toward an unfailing micro-analysis, the microscope equipment should be perfect mechanically as well as optically.

The Leitz Micro-Metallograph "MM" possesses all the required qualifications to render a microscopic image of unequalled brilliancy, definition and flatness of field.

The Change of Microstructure and Properties by Heating of High Manganese Austenitic Steel. TAKEJIRO MURAKAMI & MASAMITSU MIKAMI. *Tetsu to Hagane*, Vol. 17, Mar. 1931, pages 205–226.

A high manganese austenitic steel with 12.74% Mn and 1.19% C, obtained by quenching in water from 1000° C., was heated at several temperatures from 400° to 700°, for various lengths of time up to 50 hours, during which the change of microstructure, density, hardness and magnetization was studied. In microstructure, the following changes take place: (1) separation of carbide, (2) formation of troostite (nodulus), (3) formation of martensite, (4) formation of troostite (acicular) from martensite. The separation of carbide first takes place; as the heating temperature rises, the rate of separation increases, though the quantity of the carbide decreases, on account of an increase of the solubility. The formation of troostite (nodulus) and martensite take place in temperature ranges, 420–680°, and 420–600°, respectively; in the early stage of heating, the changes proceed most readily in the vicinity of 550°, and as the heating time increases, the temperature at which the change is maximum shifts gradually to the lower temperature. The acicular troostite is formed in the temperatures above 500° from the martensite. The density increases with the separation of carbide and the formation of troostite, but decreases with that of martensite. The hardness increases with the formation of carbide and martensite, but decreases with that of troostite. Magnetization increases with the formation of martensite and troostite, though no change is observable with the separation of carbide. From these facts the process of tempering of the austenite at several temperatures was inferred. The troostites, nodular and acicular, are formed by different methods, that is, the former is formed by the Ar change as the pearlite, while the latter is formed by tempering of martensite after long heating. According to Tammann's theory, the experimental results obtained were well explained. By means of the differential dilatometer, the Ac range was determined to be 530–680° C. TM(5a)

The Ternary System Aluminum–Magnesium–Silicon. (Sistema ternario, alluminio, magnesio, silico.) L. LOSANA. (Royal School of Engineering, Turin.) *La Metallurgia Italiana*, Vol. 23, May 1931, pages 367–382, 13 references, 23 figures.

The 3 binary systems are reviewed. These show that 4 ternary systems, Al–Si–Mg_2Si; Al–Mg_2Si–Al_3Mg_2; Al_3Mg_2–Mg_2Si–Al Mg_2; and Al_2Mg_2–Mg_2Si–Mg have to be considered. In the experimental work 99.79% Al, 99.74% Mg and 99.40% Si were used. Iron was the major impurity in all. 120 alloys were made up, melting in H_2, and thermal points determined. The solid solubility of Si and Mg in Al, and that of Si and Al in Mg were especially examined. 1.8% Si and 10% Mg are soluble in Al at the solidus temperatures, and the solubility line connecting these 2 points on the Al corner of the ternary diagram is approximately straight. The line for connecting the room temperature solubility points (about 0.4% Si and 3.2% Mg) is, however, convex toward the Al corner. On the Mg corner the solid solubility at solidus temperatures is plotted at about 0.8% Si and 7% Al (stated in the text as 1.5% and 5 to 6%), but the curve is very strongly convex toward the Mg corner. Similar convexity is shown in the room temperature solid solubility line, running from about 0.2% Si to about 2.5% Al. Isothermal projections are shown. Solid solubility of Al in Si is about 5% and of Mg in Si about 5.6% at solidus temperatures. Micrographic examination of some of the alloys is said to agree with the thermal data. Corroboratory expansion tests were also made. Al alloys with more than 20% Si and 1 to 2% Mg, or 12% Mg and 1% Si, are very brittle. "Runnability" spirals in a Mg alloy containing $6^3/_4$% Al and 0.31% Si at 750° C. averaged 35 cm. in length. Raising the Si to 0.78, 1.10 and 1.76% increased the length to 41, 45 and 54 cm. Tensile and hardness tests were made on a few of the alloys studied. HWG(5a)

Advances in Microscopy. F. F. LUCAS (Bell Telephone Laboratories). *First Communications of the New International Association for the Testing of Materials*, Group A, Zurich, 1930, pages 365–363.

Statement forecasting advances planned by Lucas, using ultra-violet light. HWG(5a)

Equilibria of Phases in Binary Systems with Continuous Solid Solutions. (Phasengleichgewichte in binären Systemen mit kontinuierlichen Mischkristallreihen). E. KORDES (University of Leipzig). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 152, Jan. 1931, pages 161–196.

Empirical equations are given which refer to equilibria of phases between the crystalline and liquid state as well as between the various crystal modifications encountered in systems built up by continuous solid solutions. The same relations hold true for the change anisotrope⇌isotrope in case of mixtures of anisotrope liquids. The paper includes the discussion of the following systems: Fe–Ni, Cu–Pd, Cu–Au, Ni–Pd, Au–Pd, Au–Ni, Cu–Pd. EF(5a)

The Ternary Eutectic of Aluminum-Silicon-Beryllium Alloys. (Zur Frage des ternären Eutektikums der Al-Si-Be-Legierungen.) WILH. KROLL & ERNA JESS. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 25–28.

After rolling and thermal treatment, the ternary eutectic point was microscopically determined at 13.4% Si and 0.75% Be. Ha(5a)

Development in the Field of the Temperature-Dependent Crystal Structure Changes of Homogeneous Solid Metals. (Die Entwicklung auf dem Gebiete der temperaturbedingten Kristallstrukturänderungen von homogenenfesten Metallen.) H. ALTERTHUM. *Physikalische Zeitschrift*, Vol. 32, Dec. 1931, pages 305–306.

A summary of recent work on surface and working recrystallization of metals, theories of recrystallization, strengthening of metals, nucleus formation and growth, and crystal orientation. A bibliography of 105 references is given. (5a)

The Formation of Ferrite from Austenite. H. C. H. CARPENTER & J. M. ROBERTSON (Royal School of Mines). *Iron & Steel Institute, Advance Copy* No. 3, 1931, 35 pages.

A detailed study of the formation of ferrite on cooling is described. The variables were rate of cooling and carbon content. The behaviors of 3 steels, containing 0.10, 0.28 and 0.43% C, were described. Samples were prepared by cooling at 4 different rates through the transformation range. The shape and position of the ferrite grains depended both on the C content and the rate of cooling. A banded structure was formed in the slowly cooled 0.28% C steel. The mechanism of ferrite formation in reference to the equilibrium diagram and the results of the microscopic study is discussed in detail. JLG(5a)

On the Kinetics in Solid Solutions. (Ueber die Kinetik in Mischkristallen.) H. HANEMANN (Technische Hochschule, Berlin). *Zeitschrift für Metallkunde*, Vol. 22, Dec. 1930, page 404.

Short announcement of the "perfusion" phenomenon, which is different from diffusion. Represents certain kind of segregation taking place in solid solutions (C-steel, $\alpha + \beta$ brass). Exhaustive publication is under way. EF(5a)

Metallography. Report of A. S. T. M. Committee E4. C. H. DAVIS, Chairman. *Preprint* No. 24 for June 1931 meeting, *American Society for Testing Materials*, 2 pages.

"Kitten's ear" broadcloth, stocked by the Horne Co., Pittsburgh has been found generally satisfactory as a polishing cloth. Kersey cloth is used by some. Sulphur as a mounting medium has been recommended for some specimens. Magnification of 250× in place of 200× is recommended for the list of standard diameters. The 250× work should be done with a 8 mm. objective and a $7^1/_2$× or other suitable eyepiece. HWG(5a)

Structure & X-Ray Analysis (5b)

X-Ray Study of Some Tungsten Magnetic Steel Residues. W. A. WOOD (National Physical Laboratory). *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Oct. 1930, pages 659–667.

About 20 steels were examined. Identifies the carbide constituents of tungsten magnet steels from X-ray spectra of the residues. Constituents are tungsten carbide, mixed carbide (Fe_4W_2C), and a third compound probably due to the silicon content. No cementite is found. Tungsten carbide spacings are slightly smaller than the normal values. Suggests that in this and in the mixed carbide atomic replacement occurs. Chemical analysis of the residues as an indication of steel constituents is of doubtful value. X-ray analysis is reliable when controlled by photographs of the untreated steel. RHP(5b)

X-Ray Determination of the Solubility of Copper in Silver. (Röntgenographische Bestimmung der Löslichkeit von Kupfer in Silber.) N. AGEEW & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 50–55.

The lattice constant of silver, containing up to about 9% copper, quenched from 770–800° C., falls linearly from 4.078 to 4.029 A. U. On tempering at various temperatures, the constant is reduced. The following table shows the solubility of Cu in Ag and the lattice constants.

Draw Temp. Deg. C.	Lattice Constant A. U.	Solubility of Cu, Atomic %	Ageew & Sachs Weight %	Solubility by Hardness & Microstructure-Hansen
(0)	–	0.2(x)	0.1	–
(100)	–	0.3(x)	0.2	–
200	4.075_7	0.5	0.3	–
250	4.075_1	0.7	0.4	–
300	4.074_1	1.0	0.6	–
400	4.073_7	1.2	0.8	2.0 to 3.0
500	4.067_5	2.8	1.7	3.2
600	4.058_4	5.2	3.2	5.5
700	4.045_4	8.6	5.4	7.4
750	4.032_5	11.8	7.4	8.4
770	4.028_8	12.7	8.0	8.7
(779)	–	14.0(x)	9.7	9.0

(x) Extrapolated.

Electrical resistance measurements confirm the solubility limits. The curved solubility line, of course, shows the possibility of a heat-treatment of the type applied to duralumin. The solubility limits determined by X-ray methods give a curve similar to, but not identical with that determined by Hansen (See next abstract). HWG(5b)

The Hardness of Silver-Rich Copper-Silver Alloys (Determination of the Solubility of Copper in Silver with the Aid of Hardness Measurements). (Die Härte silberreicher Kupfer-Silberlegierungen (Bestimmung der Löslichkeit von Kupfer in Silber mit Hilfe von Härtemessungen).) M. HANSEN. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 55–58; *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 186, 1930, pages 41–48.

By quenching Ag-Cu alloys from 750° C., tempering at various temperatures, and determining Brinell hardness, the knee in the hardness-curve plotted against the percentage of copper, shows the point at which the homogeneous solid solution breaks down into two solid solutions. Microscopic examination verified the solubility curve determined on the basis of hardness. The curve does not agree exactly with that determined by Ageew and Sachs using X-ray methods. The percentages scaled off from Hansen's curve, are given in the last column of the Ageew and Sachs' table (see preceding abstract). HWG(5b)

Rolling & Recrystallization Texture of Sheet Iron. (Walz- und Rekristallisations-textur von Eisenblech). G. KURDJUMOW & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 13, 1930, pages 67–70; *Zeitschrift für Physik*, Vol. 62, No. 9–10, 1930, pages 592–599.

A study of the crystal orientation and fibering of electrolytic iron and soft iron on rolling and on recrystallization was made by X-ray methods, utilizing the intensities of the reflections for the plotting of "pole-figures" after the suggestion of Wever (*Mitt. K. W. Inst. für Eisenforschung* Vol. 5, 1923, pages 69–77). The data on the rolling-texture do not agree with the simple explanation that the crystals arrange themselves with a cube surface in the rolling plane and a diagonal in the direction of rolling. The rolling texture is not entirely lost upon recrystallization and may even persist after the specimen has been heated into the austenitic field and slowly cooled. The article must be read with reference to the figures to be understood, and the original should be consulted. HWG(5b)

X-ray Investigations on the Age-Hardening of Duralumin at Room Temperature. (Ueber röntgenographische Untersuchungen der Kaltvergütung des Duralumins.) J. HENGSTENBERG & G. WASSERMANN (I. G. Farbenindustrie & Kaiser Wilhelm Institut für Metallforschung). *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 114–117; *Mitteilungen der deutschen Materialprüfungsant*, Sonderheft XVII, 1931, pages 34–38.

Investigations on duralumin proved that the interference lines of powder photographs are enlarging during the age hardening process at room temperatures. The intensities of the lines slightly increase while the intensities of the diffuse scattered radiation decrease. The authors conclude that, during the natural age hardening, an enrichment of Cu-atoms takes place to a very small extent within the aluminum space lattice. The precipitation of new crystals with the space lattice of copper ($CuAl_2$), i. e. of a heterogeneous phase, is denied. EF(5b)

The Lattice Constants of the Elements. WILLIAM HUME-ROTHERY. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Aug. 1930, pages 217–244.

Study of the measured lattice constants shows that in any sub-group of the periodic table, if the coördination number remains constant, the interatomic distance d is given by the relation $d/n = (1/aZ)x$, where n is the principal quantum number of the outermost shell of electrons remaining attached to the ions, Z is the atomic number, x is constant which is the same for groups with the same number of electrons in the outermost shell, and a is the second constant which in some groups may be connected with the valency. Following table shows the value of a and x.

Group	Elements	a	x
I A	Li, Na, K, Rb, Cs	0.0157	0.344
II A	Be, Mg, Ca, Sr, Ba	0.02265	0.35

RHP(5b)

Collected Information on Atomic Structure. (Strukturbericht, 1913–1928.) P. P. Ewald & C. Hermann. Supplementary volume to the Zeitschrift für Kristallographie. Akademische Verlagsgesellschaft, Leipzig, 1931. Cloth, $6^1/_2 \times 9^1/_2$ inches, 818 pages. Price 47 RM.

This well-bound and well-indexed volume is a reference book of quantitative data on crystal structure, summarized and classified with great completeness for the period 1913–1926, with addenda for 1926–1928, not so fully classified but indexed thoroughly, and with some corrections from work up to February 1931. The compilation is a very serviceable one. All available data from X-ray crystal structure determinations are given, so that the lattice type, lattice constants and atomic spacing can be easily found. In the case of many elements and compounds, the lattice structure is shown in diagrams. The results of each worker are abstracted, with reference to the original, to show the sort of material studied, the method used, and the results obtained.

Elements, chemical compounds both mineral and artificial, alloys, and organic compounds are dealt with. Of the first 500 pages, about 400 are chiefly of value to the mineralogist and 100 to the metallurgist.

The next 100 deal with alloys and include 44 equilibrium diagrams that have been established or cleared up by X-ray methods. The next 125 deal with organic substances. About 30 pages of the material dealing with investigations from 1926 on are of metallurgical interest.

The material is so well summarized that it will seldom be necessary to refer to the original sources.

Data are piling up so fast that their summarizing by experts and their orderly arrangement is a very useful service. Books of this nature are becoming increasingly needed, especially in a field such as this where much of the important data appears in a variety of periodicals, not all of which are ordinarily available to those who might use the data. Current abstracts, if properly made by experts in the field, serve to make such data more readily available, but in any rapidly growing field of knowledge, the collection of the new data into books of this type every few years is essential. It saves the time of many workers, and those who have the ability and the patience to make such compilations do a real service to their science.

This is a useful type of book, and a good book of its type.—H. W. Gillett (5b)-B-

On the Cold Working of Platinum Wires and the Fibrous Texture Thereby Produced. Gilbert Greenwood. *Zeitschrift für Kristallographie*, Vol. 78, June 1931, pages 242–250.

The side of the unit cell of platinum was found to be 3.912 A. U. Cold working platinum wire gave it a fibrous structure in which the crystallites have their (111) direction parallel to the fiber axis. The fibrous texture is slightly conical in shape. PRK(5b)

Rolling and Recrystallization Structure of Regularly Surface-Centered Metals. III, IV, V. (Walz- und Rekristallisationstextur regulär- flächenzentrierter Metalle. III, IV, V.) V. Göler & G. Sachs. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 90–101.

A great many diffraction patterns show the relations of the changes going on in the structure in annealing sheets. The results of former investigations are mostly corroborated. The paper must be referred to as it can not well be given briefly. 44 references, supplement the article. See also *Metals & Alloys*, Vol. 1, Mar. 1930, page 427. Ha(5b)

The Refining of an Aluminum Alloy as Seen in the X-Ray Photograph. (Die Veredelung einer Aluminiumlegierungen im Röntgenbild.) V. Goeler & G. Sachs. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 33–43.

A relation between structure and refineability was sought on the basis of diffraction patterns taken with X-rays. It was found to be very complex. For instance, a refining directly after quenching or after aging for some time show quite different qualities. The principal condition for refining is to suppress the disintegration of the solid solution which is oversaturated at room temperature. 34 references. See "Appearance of Heat Treatment of Duralumin in the X-ray Photograph," *Metals & Alloys*, Vol. 1, Dec. 1929, page 285. Ha(5b)

The Size of the Unit Cell of Titanium Carbide. L. R. Brantley. *Zeitschrift für Kristallographie*, Vol. 77, May 1931, pages 505–506.

From powder photographs, it was found that the size of the unit cell for titanium carbide was 4.31 ± 0.02 A. U. PRK(5b)

Tensile Tests on Crystals of Copper and α-Brass. (Zugversuche an Kristallen aus Kupfer und α-Messing.) V. Goeler & G. Sachs. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 108–126.

The deformation changes during a tensile test in a gliding system are determined by X-rays. It can be stated that all crystals have a definite elastic limit; the effective compression tension at this limit increases rapidly at first and then more slowly. The individual results are reproduced in photographs, tables and diagrams. 50 references. Ha(5b)

Comparison Standards for the Powder Spectrum Method: NiO and CdO. C. J. Ksanda. *American Journal of Science*, Vol. 22, Aug. 1931, pages 131–138.

With an improved spectrographic powder method, the size of the unit cell of CdO and NiO has been redetermined with molybdenum radiation. The length of the edge of the unit cube is $a_0 = 4.689 \pm 0.003 \times 10^{-8}$ cm. for CdO, and $4.171 \pm 0.003 \times 10^{-8}$ cm. for NiO. The calculated density = 8.2 for CdO and 6.8 for NiO. Diffraction data from natural nickel oxide, bunsenite, agree with those of NiO, and from the character of the lines present, bunsenite has a face-centered cubic arrangement of 4 molecules of NiO. Determination of refractive index, microscopically by immersion, yielded $n = 2.44_{LI}$ for CdO, and $n = 2.37_{IL}$ for NiO. WAT(5b)

Recrystallization of Aluminum. I. Kenzo Tanaka. *Memoirs College of Science, Kyoto Imperial University*, Vol. 13, Series A, Mar. 1930, pages 117–125.

Crystals produced by recrystallation in slightly deformed single crystals of aluminum tend to have a definite orientation with reference to that of the mother crystal. The orientation is little affected by the direction of the stress applied before annealing, or the type of deformation produced by the stress. WHB(5b)

Elements of X-Ray Analysis by the Powder Method. L. W. Keehan. *Metal Progress*, Vol. 19, June 1931, pages 71–76.

The history and advances in this method of X-ray study are described. Methods of reporting and describing results and experimental technique are briefly discussed. WLC(5b)

X-Ray Investigations on the Crystal Structure of Hardened Steel. Einar Oehman. *Iron & Steel Institute, Advance Copy* No. 12, May 1931, 19 pages.

An X-ray study of quenched steels confirmed the existence of the tetragonal phase whose axial ratio increased with increasing C content. From a consideration of these data it is concluded that martensite consists of a solid solution of C in body-centered iron. On effective quenching the tetragonal phase has the same composition as the parent austenite, as proved by the direct relationship between C content and space lattice dimensions. It appears probable that the C atoms dissolved in α-iron form a complex substitutional group in which 2 C atoms replace one iron atom. On tempering the tetragonal phase decomposes continuously with a progressive decrease in axial ratio. The causes of the hardness of martensite are discussed. Contains 47 references. JLG(5b)

Radiograph of aluminum alloy piston made soon after mold was put into operation.

View of piston after experimental work to determine a satisfactory method of operating the mold.

"Saving Us thousands of dollars"

—says automobile manufacturer

TO DETECT mistakes ***before*** manufacturing operations are carried through rather than ***afterwards***—that's the way manufacturers are saving money by frequent use of the x-ray today. One automobile firm informs us that it was able to save thousands of dollars in manufacturing through making a preliminary x-ray inspection of the component parts before production was started.

There is an important story for you in our recent booklet "Industrial Application of the X-Ray." Write for complimentary copy. Our research department stands ready to collaborate with you in determining to what extent the x-ray can be used in your business. Fill in, clip and mail the convenient coupon.

The Optics of X-Rays. ARTHUR H. COMPTON. *Journal of the Optical Society of America*, Vol. 21, Feb. 1931, pages 75–89.

Author reviews early studies of the properties of X-rays and the theories advanced before Laue's discovery of crystal diffraction establishing the wave characteristics of these rays. After a review of the well-known recent researches, the paper then discusses less familiar aspects of the application of the optics of X-rays. First and perhaps most important comes a summary of recent elaboration of the methods of the Braggs, that has made possible a direct investigation of the arrangement of electrons in atoms, also studies of the structure of molecules of gases by means of diffraction patterns which is very much like the measurement of the average diameter of water drops in atmospheric haze from the size of rings around the moon on certain nights. In the case of monatomic gases, it is then pointed out how the study of X-ray diffraction has revealed *the form of the atom itself!* One of the current problems of X-ray optics is the counting of the number of molecules in a cubic centimeter of a crystal, and this method is explained in mathematical detail. The statement is made that the straightforward application of optical methods to X-ray diffraction enables us to obtain our most reliable standard for X-ray wave length. Equally important are the current researches to determine one of nature's fundamental constants, namely the ratio of the charge to the mass of the electron. This appears to have slightly different values according to the method by which this constant is measured. This is discussed in detail, including last year's work by Dr. Stauss in developing a precision method of determining X-ray refractive indices. MFB(5b)

Structural Analogies of Binary Alloys of Transition Elements with Zinc, Cadmium and Aluminum. (Strukturanalogieen der binären Legierungen von Uebergangselementen mit Zink, Kadmium und Aluminium.) W. EKMAN (University of Stockholm). *Zeitschrift für physikalische Chemie*, Section B, Vol. 12, Feb. 1931, pages 57–78, 14 tables, 18 references.

The crystal powder interference method was applied to investigate phases of the following systems: Fe–Zn, Co–Zn, Ni–Zn, Rh–Zn, Pt–Zn, Ni–Cd. The photograms obtained correspond to the interference image of γ brass. The phases were located at a valency electron concentration of approximately 21:13, presumably the transition elements are considered as zero valent. The Fe–Zn phase showed a homogeneity range between 19 and 23 atomic % Fe. The Co–Zn phases and the Ni–Zn phases are homogeneous between about 15–22 atomic % Co and 15–19 atomic % Ni. In the Co–Zn system, a phase was found, the crystal structure of which is identical with β-manganese. A phase analogous to β-brass was established in Co–Al alloys. The range of homogeneity of this phase includes a concentration in which the valency electron concentration amounts to 3:2 if Co is considered as zero valent. The volume per atom has been calculated for the phases investigated, proving that the formation of the phases is accompanied by a considerable contraction. EF(5b)

Laws Governing the Crystal Structure of Hydrides, Borides, Carbides and Nitrides of the Transition Elements. (Gesetzmässigkeiten im Kristallbau bei Hydriden, Boriden, Carbiden und Nitriden der Uebergangselements.) G. HÄGG (University of Stockholm). *Zeitschrift für physikalische Chemie*, Sec. B, Vol. 12, Feb. 1931, pages 33–56. 7 references.

Phases consisting of H, B, C, N and the transition elements display typical metallic properties in contrast with phases of these metalloids and other regular metals. If the ratio between the atom radius of the metalloid and the atom radius of the metal does not exceed 0.59, structures result which may be considered as imbeddings of metalloid atoms into the spaces of very simple metal space lattices. Phases with "imbedding structures" are mostly homogeneous if approaching the composition M_4X, M_2X, MX and MX_2, the peculiarities of which are discussed at length. The space lattice of all normal "imbedding phases" investigated, yielded 4 arrangements among which the face centered cubic lattice was the one most commonly encountered. This was the case with the MX phases, while the M_2X phase was usually crystallizing in the hexagonal close packed arrangement. The body centered cubic lattice and the simple hexagonal arrangement with the axial ratio 1 were found in only a few cases. In case of the normal "imbedding structures," the metalloid atoms are always arranged within the metal space lattice in such a manner as to yield a maximum coördination number. EF(5b)

Metallic Nitrides, Carbides, Borides and Hydrides. (Metallische Nitride, Karbide, Boride und Hydride.) GUNNAR HÄGG. *Metallwirtschaft*, Vol. 10, May 15, 1931, pages 387–390.

Some nitrides, carbides, borides and hydrides have metallic characteristics while others are decidedly non-metallic, some even gaseous. The metallic group contains metals belonging to the transition elements which have characteristic atomic structure. The metallic condition appears to be connected with the small dimensions of the metalloid atoms. These compounds are important as all metals used for alloying steel belong to the transition group. In each series of transition elements the combining power of the metalloid atoms with the metals decreases with rising atomic number of the metals. Some characteristics of some of the nitrides are described. Borides have not yet been thoroughly investigated. X-ray examination of nitrides, carbides and hydrides discloses that in most cases the metal atoms have a crystal lattice of very simple structure. One condition is that the metalloid atom is small compared to the metal atom. If the ratio of their radii is less than .59 the lattice is simple. Most of them are cubic close packed or hexagonal close packed. The atomic structure of some compounds is discussed in detail. CEM(5b)

X-Rays in Engineering Practice. V. E. PULLIN. *Engineering*, Vol. 130, Dec. 19, 1930, pages 785–788. Discussion, pages 779–780.

Condensed from paper read before the Institution of Mechanical Engineers, Dec. 12, 1930. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 794. LFM(5b)

Fine Structure of Zinc Lines in the Visible and the Ultra-Violet Regions. WALI MOHAMMAD & PREM NATH SHARMA. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Nov. 1930, pages 916–921.

Give results of experiments and calculations. Bibliography of 13 references. RHP(5b)

Quantitative Chemical Analysis by Means of Absorption of X-Rays. (Quantitative chemische Analyse mittels Absorption von Röntgenstrahlen.) N. H. MOXNES (University of Göttingen). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 152, Feb. 1931, pages 380–408.

A new analytic method was developed based on the absorption of X-ray line-spectra. A description of a photographic-photogrametric method for measuring X-ray intensities is given. The practical utilization of the method is demonstrated by an analysis of Zn and Ni. EF(5b)

X-Ray Analysis of Cu-Mn Alloys. (Röntgenanalyse der Kupfer-Manganlegierungen.) ELIS PERSSON ((University of Stockholm). *Zeitschrift für physikalische Chemie*, Sec. B, Vol. 9, July 1930, pages 25–42.

By adding a few percent of Cu and by quenching, the γ-Mn-phase stable at high temperatures can be secured at room temperatures. The continuous transition of Cu into the γ-Mn-phase with rising Mn contents is discussed. By various thermal treatments, the border line of the different phases in the Mn–Cu constitutional system was established. A solubility of Cu in α and β Mn could not be proved by means of X-rays. The parameter of the Cu-phase increases with rising Mn contents from 3.608–3.74 A. U. up to 50 atomic % of Mn and then remains practically constant up to the border line, i. e., up to alloys containing 83 atomic % of Mn, presumably the alloys are quenched from high temperatures. The atomic volume of the 2 simply built phases seems to be continually changing. Over the whole concentration range, the formation of alloys built up by these phases is accompanied by a considerable expansion. EF(5b)

Non-Destructive Testing with Gamma Rays. ROBERT F. MEHL. *Iron Age*, Vol. 127, May 21, 1931, pages 1651–1655.

Of the 2 methods of non-destructive testing—magnetic, X-ray and gamma ray—the last mentioned has been studied and developed most recently. Gamma ray radiography is similar in principle to X-ray radiography. The differences between the 2 methods are: (1) differences of penetration and scattering of the ray resulting from shorter wave-length; and (2) differences in manipulation resulting from differing physical features of the equipment. The time of exposure is important. The outstanding feature of the method is its simplicity and convenience of operation. Radiographs of varying sections are possible. Includes results of tests on steel castings and welds. Taken from a paper read before the New York members of the American Society for Steel Treating and the American Welding Society. VSP(5b)

The X-Ray Test in Welding Technique. (Die Röntgenprüfung in der Schweisstechnik.) KANTNER. *Die Schmelzschweissung*, Vol. 9, Apr. 1931, page 88.

The advantages of testing of finished materials by X-ray methods is emphasized. In spite of the considerably higher investment costs for equipment sufficient to penetrate 2 to 3 inches of iron the operating expenses are less than those required for metallurgical or chemical tests; besides no material is destroyed, and what is more, this method is superior to magnetic tests, although neither method destroys the test piece, because it can also be applied to non-ferrous metals. Ha(5b)

X-Ray Test Equipment for Materials of the Deutsche Reichsbahngesellschaft in the Welding Laboratory of the Repair Shops Wittenberge. (Röntgenprüfanlagen für Werkstoffe der deutschen Reichsbahn-Gesellschaft in der Schweisstechnischen Versuchsabteilung des Reichsbahn-Ausbesserungswerkes Wittenberge.) C. KANTNER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Mar. 28, 1931, pages 399–400.

The equipment consists of a high-tension apparatus which can produce alternating current with one suppressed half-wave of 120,000 volts, constant direct current of 250,000 volts and pulsating direct current of 300,000 volts. The apparatus can be dismantled and mounted on railroad cars for tests at other places. Ha(5b)

General Principles. Physics and Technology of the X-ray Method. (Allgemeine Grundlagen. Physik und Technik des Röntgenverfahrens. Radiologische Praktika, XIV.) M. BRENZINGER, A. JANITSKY & E. WILHELMY. Georg Thieme, Leipzig, 1930. Cloth, 7 × 10 inches, 237 pages. Price 25.50 RM.

This book is volume XIV of an excellent series designed particularly for the medical applications of X-rays. This volume, however, is applicable to every branch of X-ray science. It is really a combination of three monographs as follows:

Part I. The Physical Principles of the X-ray Method by Wilhelmy.
Part II. X-ray Apparatus by Brenzinger and
Part III. X-ray and other Vacuum Tubes by Janitsky.

Under the first subject an extraordinarily clear and complete treatment is given of all fundamental principles including the laws of electric current. Previous knowledge of electricity and of X-rays is not assumed but the best possible development in minimum space has been the result of the painstaking effort of the author. It is doubtful if a better presentation could be made in 91 pages. Expecially interesting and valuable is the treatment of absorption and scattering of X-rays as applied to the understanding of filtration. It is doubtful if some of the roentgenologists know just why they are using sheets of copper and aluminum interposed between the X-ray tube and the patient being treated with X-rays. By a series of illustrations and excellent analogies the process of homogenizing a beam of X-rays characterized by many wave-lengths is clearly illustrated. The part devoted to X-ray apparatus is well illustrated and particularly interesting in that it presents very largely German practice and equipment designed particularly for medical diagnosis and therapy. The high tension equipment of American manufacturers is not overlooked, however, and there are several illustrations of various types of units manufactured in the United States. Part III. devoted to X-ray tubes, valve tubes, rectifiers and cathode ray tubes in the opinion of the reviewer is the best and most interesting treatment on modern X-ray tubes, particularly for medical purposes, which has yet appeared. The progress made in tube design and performance in Germany and Holland is really amazing. The very newest devices of all kinds are fully explained and illustrated for all types of tubes now in common use except those which are designed for diffraction analysis. The book would be a very welcome addition to the library of anyone interested in any branch of X-ray science. All three authors have written with the greatest care and in every possible way have tried to illustrate each point with practical examples. While, of course, German methods and practice are necessarily emphasized, the book is unusually broad in recognition of contributions of workers in other countries. The book is excellently printed and well bound and is free from errors.—G. L. Clark (5b)-B-

Structure of Rolled Metals and Its Change due to Amount of Reduction. (Die Walztextur und ihre Veränderung in Abhängigkeit vom Grade der Verformung.) E. F. BACHMETEW. *Metallwirtschaft*, Vol. 10, June 5, 1931, pages 451–454.

Contains 9 references. Sheet aluminum and duralumin were cold rolled with various degrees of reduction and tensile tests and X-ray examinations were made. It was found that with reduction in thickness up to 30% no crystal orientation takes place. The "maximum strength" (quotient of maximum load and cross section at the moment of the maximum load during tensile test) remains the same. During the second stage of rolling, up to about 70% reduction, an increasing tendency towards orientation and growth of the crystallites takes place. This is the transition period between quasi-isotropy and anisotropy. This was determined from the appearance of the Debye-Scherrer rings. During this stage the maximum strength increases with the amount of reduction. In the third stage, over 70% reduction, the highest degree of anisotropy, has been reached, and further reduction causes an entire change in the orientation. The orientation axis proceeds in the direction of the (111) axis. The maximum strength increases rapidly during this stage. CEM(5b)

X-Ray Investigation of Iron and Manganese Alloys. A. OSAWA. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 293–305.

In English. Five phases are found in the Fe–Mn system—body centered from 92 to 100% iron, a hexagonal phase from 78 to 84% Fe, α and β manganese from 0 to 35% iron (at a sufficiently high temperature) and a solid solution of γ-iron and γ-manganese throughout the whole series. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 845. HWG(5b)

X-Ray Investigation of Certain Nickel Steels of Low Thermal Expansion. G. PHRAGMÉN. *Iron & Steel Institute, Advance Copy* No. 14, May 1931, 10 pages.

Precise measurements of the lattice dimensions of Ni-Fe alloys at various temperatures proved that the low coefficient of expansion of alloys containing about 36% Ni is a property of the face-centered cubic lattice of this composition, and is therefore not due to a 2-phase reaction. The study was made on alloy strips, which could be heated electrically, in a camera utilizing the Bragg focusing principle. At room temperature the maximum lattice parameter occurs in alloys containing about 38% Ni. It is suggested that the specific volume anomaly may be connected with the anomaly of expansion. Contains 6 references. JLG(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

The Measurement of Large Brinell Impressions in Steel Rails. H. H. MORGAN & J. R. MOONEY (Robt. W. Hunt Co.). *Preprint* No. 36 for June 1931 meeting, *American Society for Testing Materials*, 6 pages.

In making tee and girder rails, hardness tests are made with a 3/4" (19 mm.) ball and 100,000 lb. load. Girder rails are accepted or rejected on this basis. On account of the bulging about the impression, neither diameter nor depth measurements give true Brinell figures, the diameter figures being the closer, but they are erratic. A special gage was designed and is described which measures the depth from the top of the piled-up ridge so that point in the impression where the diameter is 0.436". To this distance the gage, by a zero setting, automatically adds 0.07". The gage is checked upon a standard calibration block. The Hunt gage gives Brinell's averaging within one point of the figure obtained with the standard ball, and the average error is only about 1 1/2%. HWG(6)

Properties and Mechanics of Materials. P. G. LAURSON & W. J. COX. Wiley & Sons, New York, 1931. Cloth, 6 × 9 inches, 353 pages. Price $3.50.

This is an elementary text-book for sophomore students, and not a reference book. It refers to mechanical testing only enough to let the student understand what the data from a tensile test refer to. Fatigue and impact testing are passed over with scarcely more than the mention that they exist.

The description of the properties of metallic materials of engineering is decidedly elementary. From the pedagogic point of view the relative emphasis is probably about right, but readers other than sophomores will not find much they do not already know in the metallurgical part of the book.

The mechanics part is also elementary, but well chosen for its purpose. In reference to building codes, etc., the latest ones are used, and in general the treatment is up to date.

It seems unfortunate that in reference to key-ways on shafting there is no hint that the stress due to the notch is greater than that indicated by the normal formulas. The possibility of failure from local stress, corrosion, fatigue or wear, and the high temperature properties of metals are either not mentioned at all or dismissed with a word.

The book sets out to be a good elementary text-book. It is just that and that only.—H. W. Gillett (6)-B-

Tests on Cast-Iron Specimens of Various Diameters. J. T. MACKENZIE. Appendix II to Report of Committee A3, A. S. T. M. in *Preprint* No. 11, for June 1931 meeting, *American Society for Testing Materials*. 6 pages.

Gives breaking load, modulus of rupture, deflection and modulus of elasticity on 7/8" diameter, 12" span; 1.20" diameter, 18" span; 2.20" diameter; 18 and 24" span, and Brinells on the 3 sizes, for 36 heats of cupola and electric furnace cast iron. 12 heats contained around 2% Ni, 1/2% Cr, and two, around 12 1/2% Ni, 2% Cr. It was hoped that the properties of the 7/8" and 2.2" bars could be predicted from those of the 1.20" bar, but this was found not to be the case. The author advocates the use of 3 sizes of test bars. HWG(6)

Brown-Lipe-Chapin Gear Testing Fixtures. FRED C. RAAB. *Metal Progress*, Vol. 19, Mar. 1931, pages 47–52.

While service in the car is recognized as the final criterion of the worth of differential gears, short time tests are in use by gear makers for determining the relative merits of different steels and different heat treatment of the same steel for gears. This sort of tests as used by Brown-Lipe-Chapin are described and discussed. Limited application of the tests and careful interpretation are essential in their use for developing better gears. WLC(6)

Study of Broaches with Different Cutting Angles and Breadth of Face. (Untersuchungen von Raumnadeln mit verschiedenen Schnittwinkeln und Fasenbreiten.) A. MANN (Tech. Hochschule, Dresden). *Berichte über betriebswissenschaftliche Arbeiten* (V. D. I. Verlag, Berlin), Vol. 2, 1929, pages 35–51. 51 figures, 200 references.

Study of power consumption, best tool angles, type of chip formed and effect of lubricants in broaching cast iron, steel of 84,000 and of 65,000 lbs./in.² tensile, a 60 1/2% Cu, 1% Pb brass of 65,000 tensile, another of the manganese bronze type of 59,000 tensile and also drawn down to 69,000 tensile. Results are shown in many complex diagrams. HWG(6)

The Friction of Wire Cables In Clamps. (Die Reibung von Drahtseilen in Klemmen.) L. KLEIN. *Glückauf*, Vol. 67, Jan. 1931, pages 81–85.

The friction of wire cables in cast iron or steel jaw clamps, coated with soft metals is shown by friction number curves. Results are given for straight strand and twisted cables, varying wire diameters, and for lead and zinc composition coatings, for pressures from 45 to 250 kg./cm.² Calibration tests show that the friction number μ_1 (friction between wire cable and soft metal) varied inversely as the acceleration, more so with zinc mixture than with lead. The friction number curves in relation to pressure showed that more uniformity was gotten with zinc than with lead. Numbers were slightly higher throughout for straight stranded cables than for twisted cables. Soft metal compositions and Brinell hardness given. DTR(6)

The Unbalanced Alternating Current Bridge for Magnetic Analysis. II. W. B. KOUWENHOVEN & J. H. LAMPE (Johns Hopkins Univ.). *Preprint* No. 34 for June 1931 meeting, *American Society for Testing Materials*, 11 pages.

Skin effect, or flux penetration, plays a part in the testing of thin knife blades. The older apparatus was unsatisfactory in classifying knife blades that had had improper heat-treatment from those that had had proper treatment. A new bridge with coils designed to give greater flux density, was constructed and was found to separate the specimens into classes corresponding to heat-treatment and Brinell hardness somewhat more satisfactorily than the older design The construction of the apparatus is discussed. Blades of standard heat-treatment, 450° F., 30 min. draw, ranging from 572 to 623 Brinell were compared with other groups. A group of the same heat-treatment and same hardness range gave a "separation" in the test of −10 to +7 units. A group drawn at 650° F., 503–519 Brinell, showed +45 to +61. One at 850° F., all 426 Brinell, +137 to +146. One at 950° F., 396–408 Brinell, +167 to +173. One with the standard heat-treatment, 592–623 Brinell, but with points softened to 341–408 Brinell, (heel and middle of normal hardness) showed −27 to −44. HWG(6)

Strength of Screw Threads. (Zur Festigkeit im Schraubengewinde.) W. KUNTZE. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 14, 1930, pages 35–38; *Zeitschrift Verein deutscher Ingenieure*, Vol. 73, April 6, 1929, pages 469–471.

The importance of a high ratio of "technical cohesion strength" (Trennfestigkeit) to tensile strength in satisfactory bolt stock, is emphasized. HWG(6)

Ballistic Measurement of Highly Permeable Materials. (Ueber ballistische Messungen an hochpermeablen Materialien.) HANS NEUMANN. *Wissenschaftliche Veröffentilchungen aus dem Siemens-Konzern*, Vol. 10, Mar. 1931, pages 55–71.

Two ballistic methods, the wire method and the ring method, are described for measuring materials of very high permeability; the errors are determined. The magnetic properties of Fe-Ni-alloys with small additions of Co are given which show that for certain amounts of Co an increase in the original and maximum permeability takes place and the coercive force is decreased. Numerous curves and 18 references are given Ha(6)

Testing Butt Welds by Magnetic Methods. T. R. WATTS. *Electric Journal*, Vol. 28, June 1931, pages 389–391.

Magnetographic inspection and weld-test meters are discussed. The weld-test meter is dependable only when all conditions are comparable to those under which the calibration curves were made. The relative merits and shortcomings of the magnetographic and weld-test methods of examination are indicated and the following conclusions drawn: (1) all types of faults commonly encountered in arc welding increase the reluctance, but not proportionately to the seriousness of the fault; (2) the magnetographic method is most sensitive to poor fusion, fissures or cracks which extend to the surface on which the iron powder picture is made; (3) the weld-test meter is equally satisfactory, in any position and is practically indifferent to the depth of the fault below the surface; (4) both magnetographic and weld-test meter methods should be employed to make up for some of the shortcomings of either; and (5) these methods are as satisfactory as any other known non-destructive weld-test practicable for shop use and equipment will doubtless soon be available. WHB(6)

Wear of Metals with Special Consideration of the Measuring Faces of Gages. (Abnutzung von Metallen unter besonderer Berücksichtigung der Messflächen von Lehren.) O. NIEBERDING. *Berichte über betriebswissenschaftliche Arbeiten*, VDI Verlag, Vol. 5, 1930, 25 pages.

A measuring method is developed and described which, particularly, makes the measuring of stresses and wear in gages possible. Tests have shown that this method works with sufficient accuracy. With increasing pressure at the rubbed place, the wear increases considerably. The weight of gages and the measuring pressure should not exceed that necessitated by accuracy. Liberal use of light metal will be advantageous. The wear increases rectilinearly with increasing path of friction, which means that gages wear in proportion to the degree of their use. The wear reached its best value for samples annealed at 400° C. A metallographic examination of this sample showed that the wear does not change greatly as long as the structures hardenite, martensite, troostite and osmondite exist; after their destruction, at about 500° C., the wearing resistance decreases rapidly. Chrome plating of gages is of extreme advantage. Of all materials, Widia (a tungsten carbide), has proved to be the most excellent material for gages because its resistance to wear by far surpasses that of all other materials. All tests and results are reproduced in curves and pictures. 24 references Ha(6)

Stress Measurements in Blooms and Bars Cooled on One Side. (Spannungsmessung an einseitig abgelöschten Knüppeln.) F. STÄBLEIN. *Krupp'sche Monatshefte*, Vol. 12, May 1931, pages 93–99.

When cooling a body in a liquid, the individual layers of the body are subject to stresses. Because of their magnitude, these stresses can no longer be assumed to be elastic and, for this reason, deform the body. The theory of determining these deformations and stresses is developed; an expression is derived which gives the relation of the stresses in the body to the deformations observed after planing off layer by layer. For 6 bars cooled on one side, the distribution of stress shows tensile stresses in the interior and compressive stresses on the exterior. Without subsequent treatment, the stresses are of the order of the elastic limit. They are reduced by annealing, even at 450° C., to about 1 to 2 kg./mm.² Ha(6)

The Hardness Testing of Electro-Deposits and Other Thin Metallic Coatings. HUGH O'NEILL. *Transactions of the Faraday Society*, Vol. 27, Feb. 1931, pages 41–51.

The factors involved in the hardness testing of thin metallic coatings have been analyzed, and the advantages and limitations of scratch test discussed. A machine designed by the author for other work, and using a 1 mm. hemispherical indenter, has been found suitable for the indentation and scratch testing of coatings down to less than 0.0005 inch in thickness, provided that they are not harder than about 400 Brinell. An empirical conversion curve for obtaining approximate Brinell numbers from scratch hardness numbers has been prepared. It is suggested that a one half mm. diamond hemispherical indenter on a machine of the same type would be of still greater utility, as harder deposits could then be tested. Scratch tests are recorded made on nickel deposited from baths of different compositions. WAT(6)

Physical Aspects of Structural Joints. Part II. J. C. OTHUS. *Welding*, Vol. 1, Oct. 1930, pages 824–829.

Tests were made on angles as tension nembers, both welded and riveted to gusset plates, to observe their behavior at eccentric loads and the distribution of stresses. The preparation of specimens and test arrangements are described and the test results tabulated and shown in diagrams. Welded members carried, in general, 23% more load than riveted ones. Ha(6)

Yield Point of Structural Steel, Report of A. S. T. M. Committee on. M. O. WITHEY, Chairman, *Preprint* No. 26, for June 1931 meeting, *American Society for Testing Materials*, 6 pages.

The rate of strain put on a tensile specimen held in wedge grips has a constant ratio to the speed of the head of the testing machine for speeds between 0.05" and 1 2" per minute. It has a greater ratio the thinner the specimen tested The yield points of mild structural steel are shown by the plots to be some 10% higher at a high rate of strain than at a very low rate. HWG(6)

Rockwell Hardness Testing of Metallic Materials, Proposed Methods of. J. R. TOWNSEND, Chairman. A. S. T. M. Sub-Committee on Indentation Hardness Testing. Append . I to *Preprint* No. 4, Report of A. S. T. M. Committee E-1 on Method. of Testing for June 1931 meeting, *American Society for Testing Materials*. 4 pages.

Detailed precautions in the use of the Rockwell hardness tester are set forth. HWG(6)

A Universal Wear Testing Machine. A. K. ZAITZEFF. (Polytechnic Institute, Leningrad, Russia.) *First Communications of the New International Association for Testing Materials*, 1930, Group D, pages 119–126.

Brief description and sketches of a machine for rubbing wear test specimens against steel, agate or emery cloth. HWG(6)

New Scientific Methods of Subdivided Wear Testing of Metals. A. K. ZAITZEFF. (Polytechnic Institute, Leningrad, Russia.) *First Communications of the New International Association for Testing Materials*. 1930, Group D, pages 86–94.

The faces of 3 cylinders of the steel to be tested, each 5 mm. diameter, are pressed against a revolving ring of austenitic manganese steel at a velocity of 1 meter/sec. and a load of 11 kg./cm.² Weight losses are determined at 10 minute periods, discarding the results of the first or wearing-in period. Wear of rails in service is said to agree well with the results of the laboratory tests. Good rails lost 2 1/2 to 3 mg., average and poor rail 7 to 11 in the laboratory test. Wear does not, from the tabulated tests, appear proportional to hardness, strength or composition. From experiments on a 0.40% C, 1.0% Mn steel at different heat-treatments, it is deduced that wear times the fifth power of the hardness equals a constant, up to the hardness obtained by quenching in boiling water. General discussion is given of the factors involved in wear. HWG(6)

Resistance of Steels to Abrasion by Sand. SAMUEL J. ROSENBERG. (U. S. Bureau of Standards.) *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1093–1125.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The author describes tests made using the ball mill, the sand blast and the Brinell machine for the determination of the resistance of steels to abrasion by sand. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 37. WLC(6)

The Effect of Occasional Overstress and Subsequent Annealing on Chain Steel and Welded Chain Steel. H. IVAN ANDREWS. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, 1930, *Applied Mechanics*, pages 113–115.

The results of the test reported in this paper indicate that occasional overload tends to increase the static and fatigue strength of unwelded chain steel at the expense of the ability to resist the energy of shocks. They also indicate that the effect of annealing after overstress is to reduce the static and fatigue strength of the unwelded metal to values as low or lower than those for the metal before overstress, and that the benefit of annealing consists in the complete or partial restoration of the shock-resisting capacity of the metal. (6)

On the Vibration of U Bars. G. H. KEULEGAN. *Bureau of Standards Journal of Research*, Vol. 6, Apr. 1931, pages 553–592.

A theoretical study has been made of elongated and short U bars with special reference to their use as vibrators in investigations on elastic hysteresis. First, an expression for the frequency of the fundamental mode of vibration of the elongated U bar is derived by solving the differential equations of motion of the yoke and of the prongs through the use of an approximation. The physical basis of the approximation is the fact that the bar vibrates with a pitch differing slightly from that of the clamped-free bar of half the length. Secondly, Ritz's method of approximation is developed for initially curved bars, the development being based on the principle of least action. In this connection a new proof is given of Rayleigh's method for determining the fundamental mode of vibration. As an illustration of Ritz's method, the example of the free-free bar is treated, and the results of the calculation are compared with the known solution of this problem. Next, the method is used to determine the fundamental mode of vibration of the short U bar, a short U bar being defined as one wherein the length of the curved portion, or the yoke, is equal to the sum of the lengths of the two parallel prongs. Finally, Rayleigh's method is used to determine the static deformation of the short U bar, produced by the application of a single load so applied that the deformation is most nearly that present in the fundamental mode of vibration. WAT(6)

Modern Testing of Hardness. HENRY PERCIVAL. *Western Machinery World*, Vol. 22, June 1931, pages 247–249.

Reviews briefly the various types of hardness testers, and describes the Monotron hardness tester. A point is pressed against the test piece until a standard fixed depth of penetration has been reached. The pressure required to secure this standard depth is the value measured directly and becomes the hardness value. WAT(6)

Commercial Tests for Cast Iron. H. W. SWIFT. *Foundry Trade Journal*, Vol. 44, Apr. 16, 1931, pages 273–276, 280.

Deals with the tensile, compression, hardness, and transverse tests and then discusses the effect of mass upon the mechanical properties of cast iron. A description of tests made on bars cast in various diameters from 1/2 inch to 3 inches is given, as well as of tests made on cast plates of different dimensions. Criticism is made of the standard test pieces specified by the British Engineering Standards Association for cast iron. Some reference is made to results of tests on separate and cast-on test bars and to the effect of removing the skin from test pieces. The paper is accompanied by 7 diagrams and 3 tables. OWE(6)

Testing Steel for Forging. ADAM M. STEEVER. *Metal Progress*, Vol. 19, June 1931, pages 45–47.

The author describes and discusses testing methods and control of the quality of forging steel stock. WLC(6)

Simple Methods for Investigating Iron Castings. (Einfache Verfahren zur Untersuchung von Eisenguss.) L. F. C. GIRARDET. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 207.

Emphasizes a new method at the International Congress of Mining, Metallurgy and Applied Geology, Liege, 1930. EF(6)

Damping Capacity of Materials. G. S. VON HEYDEKAMPF (Southwark Foundry & Machine Co.) *Preprint* for June 1931 meeting *American Society for Testing Materials*. 15 pages, 7 figures, 38 references.

The damping capacity, mechanical hysteresis or internal friction of metals is the work changed into heat during a cycle of reversed stress. The specific damping capacity, in which the damping is compared on the basis of the elastic modulus, is a better unit for comparing different materials. Hysteresis methods, temperature-rise methods and the torsional pendulum methods of determining damping are discussed. Damping capacity is a physical property, as inherent to a material as is tensile strength. The damping characteristics of a dozen steels, of brass, duralumin and Lautal, are shown in curves. Ability to damp tends to decrease danger of resonant vibration in crankshafts. Damping capacity should be considered in relation to fatigue properties. Damping tests are not of any value as short-time fatigue tests, but, instead give additional information. Materials having high damping values, like cast iron, are less sensitive to surface notches. They can be deformed more without damage than Hooke's "law" predicts. The damping test determines "dynamic ductility" and may be related to impact strength. Damping tests are a type of stress-strain determination, but are much more sensitive. They indicate that there is no true proportional limit. Damping limit measures plastic behavior. The plastic action that causes the damping effect may be related to "creep." HWG(6)

Methods of Testing Materials. (Materialprüfungswesen.) K. MEMMLER. Walter de Gruyter Co., Berlin, 1930. 4th Edition. Cloth, 4 1/4 × 6 inches, Vol. 1, 136 pages; Vol. 2, 110 pages. Vol. 3, 110 pages. Price 1.80 RM per volume.

These little volumes in the Göschen collection are by the Director of the government testing laboratory at Berlin-Dahlem, and while elementary, they are generally authoritative, and up to date.

Vol. 1 deals with tensile, compression, transverse, torsion and shear testing, with notched-bar impact, endurance, hardness, bend, cupping, wear and high temperature testing. There are 272 references to the literature. In regard to endurance, Memmler specifies 10 million cycles for steel, 100 million for nickel and still more for most non-ferrous alloys. He states that the so-called short-time endurance tests are not reliable. For short-time high temperature testing heating in oil or a fused salt bath is used at the Berlin-Dahlem laboratory. Comment on long-time creep testing is very sketchy.

Vol. 2 deals with non-metallic materials and vol. 3 with testing machines. The references in these bring the total to 455. Everything is very much condensed, but is useful as far as it goes.—H. W. Gillett (6)-B-

A Comparison of Various Sizes of Test Bars Representing Cast Irons from Five Foundries. Appendix I to Report of Committee A-3, A. S. T. M. In *Preprint* No. 11, for June 1931 meeting, *American Society for Testing Materials*. 8 pages.

Tensile, transverse and Brinell tests on 0.8, 1.2, 2 and 3 inch diameter bars cast from same ladle, on 5 irons ranging from (D) 3.42% C, 2.39% Si, to (E) 3.31% C, 2.14% Si (12% steel in mix). The strength of the stronger irons held up best in large sections. D had 29,000 lbs./in.² tensile on 0.8" bar, only 12,000 on 3", while E had 37,500 on 0.8", 24,500 on 3". Photomicrographs of specimens of all 5 irons, and tensile and hardness curves are given. HWG(6)

A Method for the Standardization of Permeameters at High Magnetizing Forces. R. L. SANFORD. *Bureau of Standards Journal of Research*, Vol. 6, Mar. 1931, pages 355–362.

The advent and increasing use of cobalt magnet steels requiring the application of relatively intense fields for magnetization has led to the development of a number of commercial permeameters for magnetic testing with high magnetizing forces. For the standardization of these instruments a method is required whose accuracy can be determined without reference to tests by any other method. An adaptation of the well-known isthmus method is described, which, under proper conditions, gives an accuracy well within the allowable experimental error and which can be made to accommodate specimens of various shapes and sizes. A criterion by which to determine whether or not the proper conditions for accuracy are obtained is given. Attention is called to the importance of magnetic uniformity in bars to be used with high magnetizing forces no less than in measurements as magnetic standards, which must be taken into account in measurements in the lower ranges. Apparatus for Automatic Measurement of Brinell Impressions. (Appareil de mesure automatique des empreintes de l'essai Brinell.) R. GUILLERY. *Revue de Métallurgie*, Vol. 28, May 1931, pages 260–264.

A description of the constructional details of a Brinell press with an arrangement for automatic measurement of the impression. JDG(6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A. S. T. M. Research Committee on Fatigue of Metals.

A Peculiar Behavior of Light Alloys in Fatigue. Correspondence from F. GIOLITTI, Turin, Italy. *Metal Progress*, Vol. 19, June 1931, pages 85–86.

The writer reports the study of elastic hysteresis in aluminum alloys and the effect of slight changes in composition on the phenomenon. WLC(6f)

The Influence of Grain Size on the Resistance to Fatigue of Mild Steel. The Effect of Cold Work, Annealing, and Overheating. (Influence de la grosseur du grain micrographique sur la résistance à la fatigue de l'acier doux. Effets de l'écrouissage, du recuit et de la surchauffe.) CAZAUD. *Comptes Rendus*, Vol. 192, June 15, 1931, pages 1558–1560.

The author determined the fatigue limit of mild steel of the following analysis: C, 0.10%; Mn, 0.45%; Si, 0.03%; S, 0.08%; P, 0.03%. This material was in the form of bars 20 mm. (0.7874 in.) diameter. The following were the mechanical properties of the bar as received:

Elastic limit	76,100	lbs. in.²
Tensile strength	80,800	lbs. in.²
Elongation, %	15.5	lbs./in.²
Mesnager number	2	

The fatigue limit of this material was found to lie between 42,000 and 42,700 lbs./in.² Samples of this steel were heated: (1) to 925° C. for two hours and cooled slowly, (2) to 925° C. for two hours and cooled rapidly in air, (3) to 1175° C. and cooled slowly. The following conclusions were reached as a result of tests made on the steel subsequent to these treatments: (1) The grain size of low carbon steel, which has a marked effect on the resistance to shock, has some influence also, though less important, on the fatigue limit. When, after a suitable annealing, a small grain size is obtained, the fatigue limit reaches its maximum value. This value is but slightly altered, provided the number of grains per square millimeter is less than 400. If, as a result of overheating, the grain size is increased, the fatigue limit can be reduced by as much as 20%. (2) Cold work, which rapidly increases the elastic limit and tensile strength, only slightly affects the fatigue limit. (3) In the case of low-carbon steel annealed under the best conditions, the ratio of the endurance limit to the tensile strength reaches the high value of 0.65, although the steel studied was not of the highest quality from the chemical point of view. (4) The fatigue limit is very close to the apparent limit of elasticity in the annealed state. OWE(6f)

The Compression of Surface. (Das Drücken der Oberfläche.) HILMAR DÖRING. *Oberflächentechnik*, Vol. 8, May 5, 1931, pages 97–99.

An abstract from the author's work, "Das Drücken der Oberfläche und der Einfluss von Querbohrungen auf die Biegungsschwindungsfestigkeit," which may be obtained from NEM-Verlag, Berlin W 10. The paper deals chiefly with compression of surface of metals and its effects upon the vibrating bending strength. The tests were conducted at Wöhler Institut and the following results were obtained: The surface of test bars subjected to compression stress above the yield point (max. reduction of cross-section from 1/2 to 1%) by means of circularly arranged rolls, would yield a higher endurance strength than those whose surface was not compressed. Thus the endurance tests conducted on various steels and non-ferrous alloys showed 15–20% increase in rotating vibration strength and from 8.5–26% in bending vibration strength. In the latter case, the compressed zone of test bar was gradually increased from the center of the bar to the ends until the breakage occurred within the compressed zone under bending stress applied by suitably arranged load to center of the test bar. In this way, the effect of varying degrees of compression was also ascertained. See also *Metals & Alloys*, Vol. 2, July 1931, page 136. ER(6f)

Construction of Fatigue Testing Machines. (Zur Konstruktion von Dauerprüfmaschinen.) W. SPAETH. *Zeitschrift für technische Physik*, Vol. 11, Apr. 1930, pages 115–118.

A system consisting of two connected oscillating masses as the principle of endurance testing machines is discussed. A brief description of an endurance testing machine for alternating torsion stress is included. 5 illustrations. EF(6f)

Stress Corrosion of Metals. D. J. MCADAM, JR. *International Association for Testing Materials, Preprint* for 1931 meeting, 19 pages.

A convenient summary of the extensive work of McAdam at the Naval Experiment Station. Corrosion-fatigue is due to the accelerating effect of stress on corrosion. Sharper and deeper pits are formed than in stressless corrosion. As pitting proceeds stress concentration at the base of the pits increases. With combined stress and corrosion, the life depends upon the cycle frequency, i. e., the time allowed for corrosion to progress. Corrosion-fatigue resistance depends primarily upon corrosion-resistance. It is not greatly affected by heat-treatment or cold-working. The corrosion-fatigue limit is a stress figure obtained under arbitrary conditions, and cannot be used directly as a basis for design. HWG(6f)

Fatigue Tests on Riveted and Welded Steel Drums and Cylinders. (Ermüdungsversuche an genieteten und geschweissten Stahltrommeln und Zylindern.) H. ILLIES. *Die Schmelzschweissung*, Vol. 10, May 1930, pages 120–121.

A test arrangement of the Babcock & Wilcox Co., which subjects steel drums periodically to varying pressures of 50% above normal operating pressure, is described. Each test comprised at least 10,000,000 changes of load. From the tests, it is concluded that welded joints can be made which reduce the fatigue strength less than does the tap for the manometer connection; it withstood 400,000 changes of load, which is about 50 times more than occur during a lifetime of a boiler; and that the strength of a welded seam depends on the kind of welding. Ha(6f)

A New Testing Machine for the Determination of Alternating Strength for Revolving Bending Stress. (Neue Prüfmaschine zur Bestimmung der Wechselfestigkeit für umlaufende Biegung.) W. SCHWINNING & E. DÖRGELOH. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, pages 186–188.

Describes a new testing machine developed for the determination of repeated stresses on wires from 1.8 to 5 mm. in diameter. Contains 7 references to previous work along similar lines. EF(6f)

On the Fatigue of Metals. Y. ASAKAWA. *Kinzoku no Kenkyu*, Japan, Apr. 1931, pages 221–236.

The author investigated the phenomenon of fatigue of metals from the magnetic and mechanical points of view; namely, he studied by magnetic and mechanical means the internal conditions of the loaded specimen in various stages of the S–N curve in the rotating beam test, or those corresponding to the various kinds of falling weight in the repeated impact test, both before and after the breaking of the specimen. The magnetic method adopted by the authors was a differential method and has such a high sensitivity that even in the case when 0.05% C steel is subjected to a very small stress, 1.2 kgs./mm.², the progress of fatigue is made evident. From the results obtained, we may conclude that the progress of fatigue is shown as the result of two magnetically opposite effects, i. e., "fineness of grain" and the "internal stress," so that the corresponding change of the magnetic or mechanical property gives an indication of the various degrees of the "cold-working" of the material. One important fact observed in the present investigation is that, even with a repeated impact by a load far smaller than "endurance limit," an increase in cold-working or the brittleness of the material can be brought about. This shows that a material which underwent a certain number of repeated impacts of a stress below its endurance limit, suffers a change of internal structure and therefore it is not the same as in its initial state. Requirements and Problems Connected with High Speed Piston Engines. (Anforderungen und Probleme des Schnellaufes bei Kolbendampfmaschinen.) F. MODESOHN. *Zeitschrift für Metallkunde*, Vol. 23, Feb. 1931, pages 67–68.

Reviews the lecture delivered at the meeting "Maschinenelemente," Darmstadt, 1930, and refers to fatigue and wear resistance problems involved in high speed piston engines. EF(6f)

Fatigue of Metals. Report of Research Committee, A. S. T. M. H. F. MOORE, Chairman. *Preprint* No. 25, for June 1931 meeting, *American Society for Testing Materials*. 1 page.

Brief progress report. Comments on Lucas' micrographs at 3500× showing cracks in martensite, and on the possibility that a stress of given magnitude may be more dangerous as a cause for a spreading fatigue crack when exerted at the surface than in the interior of a piece of metal. HWG(6f)

Fatigue Tests of Model Turbo-Generator Rotors. R. E. PETERSON. *Mechanical Engineering*, Mar. 1931, pages 211–215.

Results of tests of rotor end forgings to obtain data as to safety during operation—tests with fatigue loading only, and with superimposed centrifugal stressing. 10 figs. MFB(6f)

Fatigue Tests of Weld Metal. R. E. PETERSON & C. H. JENNINGS (Westinghouse Elec. & Mfg. Co.). *Preprint* No. 39 for June 1931 meeting of *American Society for Testing Materials*. 7 pages.

Specimens of all-weld-metal, laid on between 2 blanks 1½″ diam., where the weld metal joins the blank, and built up so that the all-weld-metal section is 1″ diam. at the midsection and has a 4½″ radius, were made up by electric welding. This gives a rough specimen, to be tested unmachined, but the specimen conforms to the proper shape to avoid local stresses other than those arising from surface roughness. Such specimens were tested, machined and polished, and in the following unmachined conditions; as welded; annealed at 1000°, and at 1700° F., peened; and peened and annealed at 1000° F. Endurance limits in that order were: 10,500 to 13,000; 15,000; 16,000; 12,500; 20,500; 18,000 lbs./in.² That is, rough welds showed a better endurance limit than machined and polished specimens. This has also been found in fillet welds and was ascribed to residual stresses. To eliminate stresses, the annealing treatments were used. A 1700° F. anneal gave coarse grain structure and was harmful. The 1000° F. anneal did not have much effect. Peening was helpful, and peening the outer layer only, was as good as peening each layer as deposited. The better behavior of the rough than the machined and polished specimens may perhaps be ascribed to the opening up of pin-holes which lower the endurance. Tests on other sizes now in progress are showing higher endurance limits than those stated above for smaller specimens and lower ones for larger specimens, so this should be kept in mind when using the figures for design purposes. HWG(6f)

Requirements of Swinging Cables, with Reference to Suspension Clamps. (Beanspruchung schwingender Drahtseile unter besonderer Berücksichtigung der Beanspruchungen an den Tragklemmen von Freileitungen.) H. M. PAPE. *Veröffentichungen des Wöhler-Instituts*, 1930, No. 7, 86 pages, 17 references, 12 tables, 27 figures.

Mathematical and experimental study of fatigue failure in cables. The life of a swinging cable is decreased by an extraordinary amount with slight increase in amplitude of vibration. Use of material of high damping ability helps to reduce the amplitude. Spacing and design of clamps to hold down the amplitude and decrease the local stress at the clamp are discussed. HWG(6f)

Fatigue Tests on Small Specimens with Particular Reference to Size Effect. R. E. PETERSON (Westinghouse Electric & Mfg. Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 1041–1056.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The paper describes a small fatigue testing machine taking a specimen .050 inch in diameter at the critical section. Data from such specimens are presented and compared with that obtained on larger ones. For ordinary steels there is no appreciable size effect, but with cast irons the results were erratic and lower. Some observations on the heating effect in specimens of different diameters are given. WLC(6f)

Fatigue Properties of Crank-Shaft Steels. (Kurbelwellenbrüche und Werkstoffragen.) KURT MATTHAES. *Luftfahrtforschung*, Vol. 8, July 1930, pages 91–120.

Fatigue Tests in Shear of Three Non-Ferrous Metals. H. F. MOORE & R. E. LEWIS (Univ. of Illinois). *Preprint* No. 42 for June, 1931 meeting, *American Society for Testing Materials*. 7 pages, 6 references, 4 figures.

Torsional fatigue tests were made on commercial Cu (49,000 lbs./in.² tensile, 15% elongation, 96 Brinell) on brass with 62% Cu, 2.8% Pb (60,000, 23%, 124) and on Duralumin (61,000, 20 ½%, 118). The tests were carried to 50 million or more cycles and calculated to 100 million. The fatigue results follow: in lbs./in.².

	Rotary Beam	Reversed Torsion	Zero to Maximum torsion
Copper	15,000	10,000	19,000
Brass	18,000	14,000	26,000
Duralumin	17,000	12,000	22,000

ELECTRO-CHEMISTRY (7)

On the Activity Coefficient of Lead Halides and on the Normal Potential of Lead. (Ueber die Aktivitätskoeffizienten der Bleihalogenide und über das Normalpotential von Blei.) H. FROMHERZ (Bayrische Akademie der Wissenschaften, München). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 153, Mar. 1931, pages 376–390.

The true activity coefficients of the lead halides were determined and the normal potential of Pb against H_2 was reexamined and found to be Pb/Pb^{++}; $E° = 0.1274$ Volts. EF(7)

Contribution to the Solution Speed of Metals in Acids. Theory of Local Elements. (Zur Kenntnis der Auflösungsgeschwindigkeit der Metalle in Säuren. Beitrag zur Theorie der Lokalelemente.) W. GUERTLER & B. BLUMENTHAL (Technische Hochschule, Berlin). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 152, Jan. 1931, pages 197–234, bibliography.

The dissolving of Fe, Cu and Ni in 0.1 *N* HCl was studied and the conditions established which render the tests in HCl reproducible. An equipment was developed permitting the investigation of the dissolution speed of metals in acids under the view point of the local element theory at constant resistivity but under conditions otherwise changing. The assumptions of Ericson-Aurén and of Palmaer concerning the hydrogen excess voltage could not be affirmed by the authors who kept track of the dissolution of Zn in 0.2 and 0.1 *N* HCl. The changes in cathode potential according to Liebreich's statements must be taken into account. The formula governing the dissolution speed of metals in acids is given. The hydrogen excess voltage existing during the dissolution of a natural element could be calculated. The changes in hydrogen excess voltage largely influence the course of dissolution and the increase of the dissolution speed. The changes in resistivity exert a minor influence. The reactions occurring during the dissolution of Zn in HCl can be quantitatively interpreted on the basis of the local element theory even in case the dissolution speed is not proportional to the conductivity of the acid. Temperature Measurements on Operating Electrodes. III. (Temperaturmessungen an arbeitenden Elektroden. III.) B. BRUZS (University of Riga). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 146, Mar. 1930, pages 356–362.

The effect on Ag, Pb, Cd, Bi, Zn and Cu electrodes are measured and compared with the temperature coefficients according to Ostwald and with new calculations of entropy of ions according to Buffington and Latimer. The results are in satisfactory agreement, thus proving the usefulness of the method applied on entropy measurements of ions. EF(7)

The Problem of the Electrolytic Dissociation, Criticism of the Principles and Assumptions of the Electrostatic Theory of Electrolytic Dissociation and the Attempt of Explaining the Latter without the Assumption of Dielectric Effects. (Das Problem der elektrolytischen Dissoziation. Eine Kritik der Grundvoraussetzungen und Annahmen der elektrostatischen Theorie der elektrolytischen Dissoziation und der Versuch ihrer Erklärung ohne die Annahme dielektrischer Wirkungen.) K. FREDENHAGEN (University of Greisswald). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 152, Feb. 1931, pages 321–379.

Thermo-dynamic derivations proving that the dissolution and ionization ability of a solvent can be dispensed with. The author's new theory assumes that the chemical affinities of the atoms are not completely satisfied when forming the molecules of a compound. On account of their chemical affinity forces, the atoms in the compounds are still able to react with other elements assuming that they are in a certain distance. Various auxiliary assumptions of the former electrostatic theory, aiming at the interpretation of the different behavior of strong and weak electrolytes, the self-dissociation of pure solvents and molten salts, the characteristic specific dissolution capacity of typical solvents as H_2O, liquid ammonia, fluoric acid, etc., are criticised and explained with the aid of the author's new theory. Electrodeposition of a High Zinc, Low Cadmium Alloy on Steel, Malleable and Cast Iron Parts. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, pages 667–670.

Alloy known as "Brite-A-Loy" consists of 90 or 92% Zn and 10 or 8% Cd. It may consist of 92% Zn, 7% Cd, and 1% Cu, which results in the hardest of the alloys when deposited. The deposit is white in color and resembles Ag, but is much harder. Although corrosion resistance has not yet been fully determined by comparative tests, it is probable that the alloy will give satisfaction under any physical tests. Steel parts should be cleaned with an alkaline cleaner. Temperature of a still cleaning solution is 200° F., while that of an electrocleaner is 180° F., the voltage being 5–6. The articles are pickled in a solution of 1 part HCl, 2 parts H_2SO_4, and 7 parts H_2O, at 120° F., and then dipped in a bath of 1–2 parts HCl and 1 part H_2O at 120° F. After washing in cold H_2O, they are dipped in a bath of 4 oz. NaCN and 1 gal. H_2O. The plating bath consists of 1 gal. H_2O, 10 oz. $Zn(CN)_2$, 5 oz. NaCN, 12 oz. NaOH, and 0.20 oz. CdO. It is operated at 80–100° F. and a c. d. of 15–30 amp./ft.² of surface area at 2½–4 volts. Anode should consist of 90–92% Zn and 10–8% Cd. Ratio of anode to cathode area is 2½:1. Time of plating may range from 5 min. up. Anode rod should always be connected with the steel tank with a ⅛ in. Cu wire. High alkalinity and low free cyanide are the important factors that will give a bright luster white finish. Alloy may be used to replace Ag deposits on electric light fixtures. If an antique finish is desired, the alloy plated articles are immersed for 5–15 sec. in a solution of 1 gal. H_2O, 4 oz. $NiCl_2$, 6 oz. NH_4Cl, 2 oz. NaCNS, and 0.5 oz. $ZnCl_2$, at 90–100° F. After washing in cold H_2O, they are brushed and lacquered. All plated articles must be thoroughly washed in cold and boiling H_2O to remove all traces of the plating solution. MS(7a)

Observations on Scraped Metal Electrodes and Their Relation to the Absolute Zero Point of the Potential. (Beobachtungen an geschabten Metallelektroden und ihre Beziehung zum absoluten Nullpunkt des Potentials.) K. BENNEWITZ & J. BIGALKE. *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 154, Apr. 1931, pages 113–135.

The scraping method formerly described is improved and tests are carried out to investigate the reproducibility, influence of resistance, of additions and temperature. EF(7a)

The Recording of the Hydrogen Ion Concentration in Nickel Plating Baths (Enregistrement du pH dans les bains de nickelage.) J. BARBAUDY, A. GUERILLOT, H. MIACHON & R. SIMON. *Comptes Rendus*, Vol. 192, Mar. 23, 1931, pages 739–741.

The authors describe a method whereby they have obtained a continuous record of the pH of a commercial nickel plating bath, the method involving the use of a recording pyrometer of the Leeds and Northrup type, graduated in millivolts from 0 to 700. A quinhydrone electrode, furnished with a gold electrode, was used as a cell. The apparatus has functioned satisfactorily for 18 hours without attention, the precision of the measurements obtained being comparable with those which have been obtained with the usual pH apparatus. OWE(7a)

Study of Buffer Characteristics in Nickel Plating Baths. (Étude de l'effet tampon dans les bains de nickelage.) J. BARBAUDY & A. PETIT. *Comptes Rendus*, Vol. 192, Apr. 7, 1931, pages 834–837.

The authors describe the results of a series of experiments on 3 baths: (1) a newly made hot rapid nickel plating bath, having the composition: nickel sulphate 450 g. per liter, nickel chloride 12 g. per liter, boric acid 22 g. per liter; (2) a used hot nickel plating bath of which the composition had been modified by additions of acid, nickel carbonate, and irregularities due to service; (3) an unbuffered nickel plating bath. From values of pH corresponding to various amounts of base (or acid changed in sign) added, measured in gram equivalents per liter, the authors obtained values for the buffering characteristics of the solutions in terms of pH, the curves showing that solutions 1 and 2 are buffered on the alkaline side even when their resistance to additions of acid is increasingly lowered as the pH falls until it reaches the value of 3.5. The solution is buffered by hydrogen ions beyond this point. Solution 3 only shows the buffering characteristic at a value in the neighborhood of pH 6 due to the precipitation of nickel hydroxide. Boric acid has the effect of preventing this precipitation, even when a base of lower pH than that causing precipitation of the hydroxide is added. The foregoing experiments were carried out at a temperature of 20° C. A further series was conducted at 50° C., when it was found that the buffer characteristics were only slightly higher than those measured at 20° C. The curves, however, exhibited a remarkable widening of the buffering zone. The article is illustrated by 2 curves. OWE(7a)

Studies in the Electrodeposition of Metals. DONALD B. KEYES & SHERLOCK SWANN, JR. *Metal Industry*, London, Vol. 37, July 11, 1930, pages 35–36; July 25, 1930, pages 87–88.

Electroplating Progress. RALPH F. COHN (Reynolds Wire Co.). *Metal Cleaning & Finishing*, Vol. 2, July 1930, pages 573–576.

Purchase of chemicals in bulk, use of liquid storage, and pipe-line handling have influenced the economic aspects of the plating industry. Illustrates by discussing some of the changes which have taken place in the electrozincing of steel. Some of these improvements are due to the introduction of corrosion-resisting materials. MS(7a)

The Practical Difficulties Associated with the Electro-Deposition of Chromium. J. W. CUTHBERTSON. *Engineering*, Vol. 130, Dec. 5, 1930, page 730.

Abstract of paper read before the Electroplaters' and Depositors' Technical Society, London, Oct. 15, 1930. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 38. LFM(7a)

Anode Rods. GEORGE B. HOGABOOM. *Monthly Review, American Electroplaters' Society*, Vol 18, May 1931, pages 4–8.

Reprint, *Metal Industry*, New York, Vol. 29, June 1931, pages 247–248. The importance of keeping anode rods clean is demonstrated by the appearance of a cathodic deposit on some of the nickel anodes used in nickel plating, which were hung from an unclean spot on the anode rod. Anodes so insulated from the anode rod, either completely or partially, act as bipolar electrodes and cause losses in anode efficiency and in anode metal. Results of laboratory experiments are given and are in agreement with the bipolar electrode theory. LCP(7a)

Determining the Throwing Power of Chromium Plating Baths with the Cavity Scale. L. C. PAN. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 753–756; Oct. 1930, pages 851–854, 876.

Defines throwing power and outlines early methods for its measurement. Author has developed an instrument for this purpose called the cavity scale. It consists of a metal bar with cavities of graded depths. The cavities are numbered according to the ratio of depth to diameter. The scale is mounted on a special rack and is plated under the conditions customarily used for regular plating. The time of the test may be the same as that in actual plating, or a fixed period to be used on all tests. The highest number on the cavities which are completely covered is taken as the throwing power of the bath. Scale should be made of the same metal as the articles to be plated. Investigation carried out with brass and steel scales showed that for the best Cr bath studied, the throwing power was 45 on the brass scale and only 30 on the steel scale, the operation conditions being the same except that a c. d. of 1 amp./in.^{2} was used on the brass scale and 1.5 amp./in.^{2} on the steel scale. When both sulphate content and c. d. are high, the throwing power of the same Cr bath is much higher on steel than it is on brass. Study of the relation between sulphate content and throwing power showed that maximum throwing power on both the brass and steel scales is obtained when the sulphate content is about 1% on the basis of CrO_3. Found that trivalent Cr is more detrimental to throwing power than presence of iron in baths. MS(7a)

Studies in the Electro-Deposition of Nickel. Part II. The Effect of Current Density and Temperature. Part III. The Effect of Small Quantities of Iron and Aluminum. J. B. O'SULLIVAN. *Transactions Faraday Society*, Vol. 26, Sept. 1930, pages 533–543.

Part II. The varied surface structures of deposits obtained from buffered nickel sulphate solutions are caused by variations in the throwing powe of the solutions. The deposition potential is a logarithmic function of the current density over moderate ranges. The slope of the deposition potential-log. current density curve and the deposition potential at unit current density vary from one solution to another. It is deduced that the constants of the Freundlich adsorption isotherm are functions of the pH of the solution and of the buffering agent employed. Part III. Small quantities of iron salts have no appreciable effect on the electro-deposition of nickel. This is probably due to preferential deposition of iron, whereby the metal is removed from the cathode film before it can form any colloidal compounds. Aluminum accumulates in the cathode film until colloidal compounds form. If this process goes far enough, the structure of the nickel deposit is altered, becoming black or "burnt." These black deposits contain appreciable amounts of aluminum; white deposits contain none; hence it is likely that the co-precipitation of colloidal aluminum with nickel accounts for the phenomenon. The view that fine grained nickel deposits are due to the co-precipitation of colloidal nickel hydroxide finds support in the above observations. OWE(7a)

Nature and Cause of the Decay of Electrolytic Silver Plating. (Wesen und Ursache der Ausblühungen auf galvanischen Silberüberzügen.) H. MOSER, K. W. FRÖHLICH & E. RAUB. *Zeitschrift für angewandte Chemie*, Vol. 44, Jan. 31, 1931, pages 97–100.

This article deals with defects in silver-plating, which are shown by the authors to be due, largely, if not entirely, to the presence of non-metallic inclusions, and, in particular, to cuprous oxide in the materials being plated. The results of experiments on a copper-silver alloy and on a nickel-silver are described and the theory outlined in the above sentence based thereon. The article is illustrated by 9 photomicrographs and 1 sketch. OWE(7a)

Electroplating on Cold-Rolled Steel. G. B. HOGABOOM. *Monthly Review, American Electroplaters' Society*, Aug. 1931, pages 7–16.

Includes discussion. Difficulties with plated steel are ascribed to finishing hot-rolled steel by a small amount of cold-rolling, so that the sheet has a coarse structure in the inside and a fine-grained surface. The material may break at the junction in forming, and if heated after nickel plating, blisters appear. Similar trouble in japanning is ascribed to difference in expansion between core and surface. Hot rolling followed by a burnishing roll produces a surface oxide film. If pickled long enough to remove the oxide, a coarse surface is produced, which does not take a good plated finish. W. Fraine commented on blisters due to slag or gas pockets in steel to be plated, and C. Van Derau pointed out that the cost of polishing out defects in cold rolled steel that contains pits, rolled-in scale, and "pips" is greater than the cost of the steel itself. Insufficient cropping is suggested as a cause for gas pockets. Steel that breaks in the draw press or that develops pits in polishing is rejected. Steel makers as a whole are ignorant of the plater's needs. HWG(7a)

Industrial 'Chromium Plating. (Industrielle Verchromung.) K. ALTMANNSBERGER. *Oberflächentechnik*, Vol. 8, Apr. 21, 1931, pages 90–91.

The ratio $\frac{\text{chromic acid (mol.)}}{\text{sulphuric acid (normal)}}$ lying between 40 and 60, as set up by Engineering Research Dept. of Michigan University for optimum throwing power in commercial bright chromium plating bath, is confirmed by the author's tests. The upper limit for sulphuric acid content of bath, according to test results, shall be 1.2%. On employing higher acid content than this, or too low, the throwing power is markedly decreased; hence milky or burnt coatings are produced. Tests reveal, also, that addition of sulphate of whatever base is used, is in its action equivalent to sulphuric acid. ER(7a)

What Constitutes a Good Base for a Standard Electroplate? E. LAMOUREUX. *Monthly Review American Electroplaters' Society*, Vol. 18, May 1931, pages 13–15.

It is emphasized that good electroplating can only be obtained on a highly polished and finished surface. Before a standard for electroplating is agreed on, a standard for the quality of the surface to be plated should also be agreed on. The bearing of this question on proper machinery and equipment of polishing rooms is discussed briefly. Ha(7a)

Value of Chromium as a Finish for Plumbing Fixtures. N. G. NEAR. *Metal Industry*, N. Y., Vol. 28, Nov. 1930, page 518.

Stresses the importance of using Ni as a base for Cr plating. A heavy plate of Cr produces minute cracks while a slash is very porous. Bureau of Standards specifies for fixtures Ni thickness of 0.002 in. and 0.00002 in. of Cr. VSP(7a)

Electroplaters' Handbook. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 987–991.

Lists the chemical, commercial and common names (with their chemical formulæ) of chemicals used in dipping, plating and coloring of metals. MS(7a)

The Maintenance and Life of Cleaning Solutions. R. W. MITCHELL. *Monthly Review, American Electroplaters' Society*, Vol. 18, June 1931, pages 30–34.

Paper before Newark Branch of American Electroplaters Society, Annual Meeting, April 1931. Metal cleaning baths lose their efficiency through (1) neutralization by acid dirt, (2) adsorption by dirt and grease, (3) drag-out, followed by dilution, (4) neutralization by CO_2 from atmosphere. Laboratory experiments show drag-out loss amounting to 1 to 2 lbs. of cleaning solution per 100 ft.^{2} of surface cleaned. Equal results were obtained by a manufacturing plant using caustic soda, 6 oz./gal. and soap, 2 oz./gal. respectively. The cost of cleaning is 10% cheaper in favor of soap. The required amount of cleaning compound in a plating shop is shown to be 0.5 to 0.7 lb./100 ft.^{2} of surface cleaned. LCP(7a)

Some Notes on Chromium Plating. MEYER ROTER. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1047–1048.

Metal concentration should not be too high for easiest possible control of a Cr solution. Specific gravity should be 30–35° Bé., with not more than 0.45 oz. of sulphate per gal. solution. Ratio of CrO_3 to sulphate is 100–1 by weight. Temperature should be about 118° F. If the bath is to be operated at lower temperature, the Cr solution may be more concentrated. Temperature should be about 5° F. lower when plating steel than when plating brass parts. Before starting to operate a solution after a lapse of time, it should be electrolized. This may be done by suspending a sheet or bar of metal on the cathode rod. Steam coils should be arranged in the bath, so that the temperature will be uniform throughout the solution. Recommends use of double Cr plate for plating uneven surfaces or parts that are poorly exposed MS(7a)

Throwing Power of Cyanide Copper Plating Baths. L. C. PAN. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 927–932; Dec. 1930, pages 1041–1044.

Describes investigation of the functions and influences of some of the ingredients and impurities in a commercial $Cu(CN)_2$ bath, with special reference to throwing power, bath voltage and character of deposit. Concludes that carbonate in $Cu(CN)_2$ baths is beneficial with regard to bath voltage throwing power and polarization. For maximum throwing power from baths containing no other ingredients than $Cu(CN)_2$ and NaCN, Na_2CO_3 should be kept between 3 and 5.5 oz./gal. $Na_2S_2O_3$ raises the throwing power, but does not depolarize the anode, nor reduce the bath voltage. Its presence is beneficial if within the limits of 0.013–0.06 oz./gal. With higher concentrations, there will be brown spots on the deposit. Addition of NaOH, preferably 0.8–2 oz./gal., improves the conductivity and throwing power, but made the deposit dull. NaCl raises throwing power and reduces bath voltage, when the concentration is between 2 and 3.3 oz./gal.; it may be used as a brightener, to overcome the disadvantages of $Na_2S_2O_3$. Recommends several formulae for Cu plating. See also *Metals & Alloys*, Vol. 2, June 1931, page 112. MS(7a)

How to Improve Durability of Chromium Plate. R. J. PIERSOL. *Chemical & Metallurgical Engineering*, Vol. 38, July 1931, pages 386–389.

For durable chrome plate, article must have contours free from sharp edges and deep recesses. Foundation metal should have fine grained non-porous structure and be free from elements which react with chromium as does zinc in brass. Nickel is an ideal intermediate plate. Automatic equipment should replace human labor and operating factors should be standardized on 15–30 minute plates which are bright, ductile, non-porous and free from excessive lateral stresses. PRK(7a)

Platers' Guidebook 1931 Edition. BY OLIVER J. SIZELOVE. *Metal Industry*, New York, 1931. Paper, 5 × 8 inches, 58 pages. Free to subscribers to The Metal Industry and Brass World.

The 1931 edition is made up of new material covering a variety of subjects in great detail, which were not included in the first edition. The scope of the new booklet can be seen from the following list of topics: Electroplating Non-Metallics, Silvering Mirrors, Cleaning, Etching, Barrel Burnishing, Polishing Before and After Plating, Plating Zinc Die Castings, Lacquering and Enameling, pH Determination.—Richard Rimbach (7a)-B-

Chromium Plating. W. H. ROWE. *Monthly Review, American Electroplaters' Society*, Vol. 18, June 1931, pages 51–56.

Paper before Hartford-Connecticut Valley Branch of American Electroplaters Society, April 27, 1931. Detailed discussion of the operation of a chromium plating plant handling a wide variety of articles. It is pointed out that barium carbonate sometimes added to the chromium plating bath to reduce excess sulphate content, often causes the bath to act erratic and difficult to restore its normal condition. Barium sulphate is not strictly insoluble in chromic acid. It redissolves gradually and upsets the chromic acid to sulphate ratio. LCP(7a)

Throwing Power of Sulfate Zinc Bath. L. C. PAN. *Monthly Review, American Electroplaters' Society*, Vol. 18, May 1931, pages 8–12.

Paper presented at the Annual Educational Session of the New York Branch, American Electro-Platers Society, Feb. 21, 1931. The cyanide and the sulphate processes of zinc plating are compared with the conclusion that the sulphate bath is superior except in the matter of throwing power. Means of increasing the throwing power of the sulphate bath are suggested such as regulating the pH value and maintaining it by a suitable buffer. For a bath containing 20 oz. zinc sulphate, dry, 6.7 oz. ammonium acetate and 2.7 oz. aluminum sulphate per gallon, the maximum throwing power is found at a pH of 4.2 (colorimetric). Bright deposit of zinc is obtained from the above bath within a pH range of 3.0 to 3.8 (colorimetric). A throwing power comparable to that of the cyanide bath is obtained by using pyridin, 0.06 oz./gal., as a buffer and a pH of 3.7. The zinc deposit from this bath is dense and bright. LCP+Ha(7a)

Barrel Plating with Zinc-Cadmium Alloys. LAWRENCE E. STOUT & I. KOWARSKY. *Metal Industry*, N. Y., Vol. 29, July 1931, pages 297–299.

Paper read before the American Electroplaters' Society at Rochester, N. Y. June 29–July 2, 1931. Bright Zn-Cd alloys, good for the prevention of corrosion of steel, were barrel plated from solutions containing sodium cyanide 9.7 oz./gal., sodium hydroxide 1.1 oz./gal. with either cadmium oxide 3.7 oz./gal. and zinc cyanide 0.8 oz./gal. or cadmium oxide 5.1 oz./gal. and zinc cyanide 0.1 oz./gal. Current density was 25–40 amps./sq. ft. at 72° C. The solutions had excellent throwing power and no addition agents were needed. PRK(7a)

Silver Cadmium Alloys for Metal Finishing. LAWRENCE E. STOUT. *Metal Cleaning & Finishing*, Vol. 3, June 1931, pages 457–459.

A cadmium-silver alloy plate containing 24% silver is produced from a bath made of

	oz./gal.
Cadmium oxide	6
Silver cyanide	0.4
Sodium cyanide	16.5
Sodium sulphate, anhyd.	6
Nickel sulphate	0.02
Turkey red oil	1.5

using cadmium anodes. The ratio of anode surface to cathode surface is maintained at 2 to 1. At a current density of 9–10 amp./ft.^{2} and room temperature, the deposit is white like silver, resists the action of sodium polysulphide and hydrogen sulphide, is ductile, uniform in thickness and easily adherent to copper, steel and other metal surfaces. LCP(7a)

Effect of Various Metallic Sulfates upon the Throwing Power of a Chromium Plating Bath. LAWRENCE E. STOUT & JONAS CAROL. *Industrial & Engineering Chemistry*, Vol. 22, Dec. 1930, pages 1324–1325.

The addition of Ni, Co, Zn, Cd sulphates to a chromic acid plating bath in the ratios of CrO_3-SO_4 of 200:1 or 150:1 increases the throwing power of the bath. Cd sulphate used in these proportions gives the highest throwpower. Ni and Co sulphates give a deposit which is much more resistant to the solvent action of HCl. Metals, as sulphates, in these proportions do not deposit at the cathode with the chromium. MEH(7a)

Plating with Rare Metals. JOSEPH ROSSMAN. *Metal Industry*, N. Y., Vol. 29, June 1931, pages 245–246.

There is given a description of recent and expired patents covering plating with platinum, palladium, rhodium and iridium. PRK(7a)

The Electrolytic Deposits on Aluminum and Its Alloys. (Die elektrolytischen Niederschläge auf Aluminium und seinen Legierungen.) M. BALLAY. *Oberflächentechnik*, Vol. 8, Jan. 20, 1931, pages 12–13.

Taken from *Comptes Rendus*, Part 190, 1930, page 305. A new process for commercial nickel plating of aluminum or its alloys is described by the author. This process gives a tightly adhering and corrosion-resistant coating. According to invention, the surface of aluminum is etched with iron chloride solution acidified with HCl preparatory to plating. The proper concentration of iron chloride and HCl is dependent upon the alloy used, but must be within the limit 6–22 g. iron and 0.10–0.70 mol. HCl/liter. The procedure of coating is as follows: (1) Removal of fats; any known bath, as for example electrolytic bath containing 10% sodium carbonate, may be used. Care must be exercised that aluminum itself is not attacked. Electrochemical treatment of surface; rinsed objects are immersed for 10–30 sec. in boiling solution of about the following composition: water 100 liters, saturated iron chloride solution (45° Bé), or solid iron chloride of proper ratio—3 liters and HCl, 1 liter. (3) Nickel bath; carefully rinsed with water, material is plated according to known method. If a subsequent chromium plating is necessary, the nickel bath must have a higher temperature and a higher current density must be employed. ER(7a)

The Practical Chromium-Plater. (Der praktische Verchromer.) *Oberflächentechnik*, Vol. 8, July 21, 1931, pages 151–153.

A general description and discussion of present chromium-plating methods; 2 are in use in Germany. One is the Langbein-Pfannhauser bath with exhauster equipment and the other is the Blasberg bath with a protective layer on it. The chromium deposit is now usually applied over a Ni deposit because the latter gives a more effective rust protection, but chromium-plating gives a harder and better surface protection of the Ni. The composition of baths, operation, preparation of the pieces, reason for failures, etc., are discussed in general. Ha(7a)

Anode Rods. GEORGE B. HOGABOOM. *Monthly Review, American Electroplaters' Society*, Vol. 18, May 1931, pages 4–8; *Metal Industry*, N. Y., Vol. 29, June 1931, pages 247–248.

Anode rods should be kept clean, otherwise the anode becomes partially insulated. This affects plating voltage as well as anodic corrosion. Ha+PRK(7a)

Electrometallurgy (7b)

New Developments in Applied Electro-Chemistry with Reference to Large Plants for Aqueous and Molten Liquid Electrolysis. (Die neuere Entwicklung der technischen Elektrochemie unter Bezugnahme auf grosse Anlagen für wässerige und schmelzflüssige Elektrolyse.) GEORG EGER. *Elektrotechnische Zeitschrift*, Vol. 51, May 29, 1930, pages 771–776, 809–815.

The present status of applied chemistry and the possible trend of future developments is exhaustively described and discussed. The article deals with the quantities of production, increase of current density both in the electrolytic baths and electrodes. Two principal methods are distinguished thus: processes with soluble anodes (refining processes) and methods with insoluble anodes. A great many diagrams show connection and wiring of the baths, the physical arrangement in the sequence of the process through the shop and during the different stages. The processes of aqueous solutions are mostly used in the electrolytic production of metals, particularly of Cu and Zn; details of the Anaconda and Taiton processes are given. Further, the electrolytic production of rare metals, Sn, Sb, Cr, Ni, Co, Mn, Cd, Pb, Fe are discussed. Information is given on modern factory methods and chromium-plating and cadmium-plating. Methods for commercial production by electrolysis of chlorine, water, electrolytic oxidation and reduction are described. The molten liquid processes are mostly used for production of light metals, Al, Mg, Be. In conclusion, electrical questions are discussed with regard to the most economical current generation and price. Photographs of factory installations and a list of references supplement the very instructive paper. Ha(7b)

Recent Advances in Technical Electrolysis. (Die neueren Fortschritte der Technischen Elektrolyse.) J. BILLITER. Verlag von Wilhelm Knapp, Halle (Saale) 1930. Paper, 7 × 9½ inches, 328 pages. Price 22 RM.

While much of this book refers to production of oxygen, hydrogen, chlorine, etc., the bulk of it deals with electro-winning or electro-refining of metals. The refining of Cu, Ag, Pb, Ni, Sn, Zn, Cd, Co, Bi, Sb, is discussed and some comment is given on production of Fe tubing and sheet by electrolysis. The description of processes for Cu and Zn are the most complete.

Under electrolysis of metals from fused salts, Na, Be, Al, including the Hoopes process, Mg, Ca, Ce, etc., Ba, Sr and Li are all discussed.

An effort has been made to deal with the commercial practice in all countries rather than to confine the description to German plants only. Some of the information is naturally hardly up-to-date, but it is rather more so than in many books of this class. A dozen flow-sheets showing the order of operations in large Cu and Zn plants are appended.— H. W. Gillett (7b)-B-

Electrochemistry and Electrometallurgy. Annual Report of Committee on Electrochemistry & Electrometallurgy. P. H. BRACE, *et al.* *Electrical Engineering*, Vol. 50, July 1931, pages 570–574.

A report for the years 1929 and 1930. The more important developments in electrochemical and electrometallurgical arts in this period, particularly as regards Cu and Zn refining, Na, Al, Ba, Be and Mg production, etc. Other subjects discussed include: carborundum, cleaning of metals, primary and secondary batteries, electric melting furnaces, water purification, sterilization of milk, electrostatic precipitation, metal powders, and some miscellaneous processes and plants. WHB(7b)

Examples of Hydrometallurgical and Electrometallurgical Operations. II. Gold and Silver. THOMAS P. CAMPBELL. *Colorado School of Mines Magazine*, Vol. 21, July 1931, pages 9–13.

The second of a series of articles on "Principles of the Metallurgy and Electrodeposition of the Metals." It deals with various phases of percolation, the arrangement of plant, slime or agitation leach, precipitation, refining, regeneration of cyanide. Percolation is divided into two classes, dry and wet treatment. The former is applied to materials coming from tailing ponds and dry-crushing mills, and the latter is applied to ores delivered wet as a flowing pulp from mills or previous treatment. A flowsheet is shown for a 500-ton combination flotation and cyanide plant. Direct operating costs and metallurgical results of Northern Ontario mills are tabulated. WHB(7b)

Electro-Thermic Aluminum. (L'Alluminio Elettrotermico.) A. PAOLINI. *La Metallurgia Italiana*, Vol. 23, July 1931, pages 603–623.

The history of electrolytic aluminum is briefly traced, that of electrothermic aluminum more fully. Electro-thermic ferro-aluminum has been produced on both the experimental and the commercial scale, containing 30–50% Al, 3–13% Si, 3% Ti, 2.5 to 3.8% C and varying amounts of Ca up to 0.4%. It is calculated that Al in ferro-aluminum can be produced at 1.1 lire/kg. contained Al against 1.9 lire for electrolytic Al. By using bauxite not too high in Fe, sand and anthracite, a silico-aluminum can be produced of 50–56% Al, 33–36% Si, 2.5–11% Fe, 2–2.5% Ti, 0.5–1.0% C and 0.5–0.9% Ca by suitable remelting and liquation, though the first product has 3 to 4% C. By using pure Al_2O_3, kaolin and petroleum coke, such alloys as 66.4% Al, 32% Si, 0.7% Fe, 0.3% C, 0.1% Ti, 0.3% Ca, 0.05% P and traces of S, can be made which may serve as a base for Alpax or Silumin though it is admitted that Ti and Ca may be inconvenient impurities and the removal of all carbides is apparently very difficult. Such an alloy should be a cheaper source of Al and Si for the Alpax type of alloys than the commercially pure metals. Calculations are stated to show that production of 99.5% Al through electro-thermic Al-Cu-Si alloys, purified by the Hoopes process should not cost more than 2 lire/kg. HWG(7b)

Some Experimental Results Obtained from the Preparation of Electrolytic Sheet Iron. C. KADOTA. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 127–131.

In English. A few experiments on making iron sheet by deposition from a chloride or chloride sulphate bath are described. The temperature used was 80° to 90° C. and current densities varied from 3½ to 6 amperes/dm.^{2} Gray or white pig iron or steel sheet was used as anode. Current efficiency is stated to be 95%. The analysis of the product is not given, but it is stated that 0.01% Cl and small amounts of Cu, P and S were found in the deposits. Sheet of 0.1 mm. is considered the most economical thickness to produce. The sheets were not free from pin-holes. HWG(7b)

Electrolysis of Molten Salts and Secondary Reactions. (L'electrolyse ignee et les reactions secondaires.) L. ANDRIEUX. *Journal du Four Electrique*, Vol. 40, Feb. 1931, pages 60–61; Mar. 1931, pages 98–100; Apr. 1931, pages 139–140; May 1931, pages 177–180.

Part 1 gives a short sketch of the development of the electrolysis of molten baths. Part 2 outlines the mechanism of electrolysis. Part 3 gives a brief description of the Heroult process for making Al and Hoopes' method for the production of pure Al and the American Magnesium Co. method for the preparation of Mg. Some general consideration regarding the electrolysis of oxides are given, particularly with the use of molten boric anhydride and a mixture of it with other salts, especially fluorides. (Recherches sur l'electrolyse des oxydes metalliques dissous dans l'anhydride borique ou dans les borates fondus. L. Andrieux. *Annales de Chimie*, Vol. 12, Nov.-Dec. 1929, pages 424–507.) Part 4. When molten borax kept at the temperature of 900° is electrolyzed using a cathode kept at about 750–800° on cooling it can be seen that next to cathode a layer of pure Na is formed, then a heavier layer of Na mixed with B, a thin layer of B and then a mass of solidified electrolyte. With higher operating temperatures the proportion of Na diminishes and at 900° only B is produced. Decomposition of Na oxide in the first stage of the reaction reduces part of the B oxide forming with the rest a metaborate. Using B_2O_3 as a solvent for oxides of reducing metals it was found that Na, K, Al and Mg reduce B_2O_3 with the formation of more or less pure B. Li, Ca, Sr, Ba, Ce and Mn produce a mixture of B with borides in which the latter predominate. With Na and K the reduction is incomplete, much oxygen is still left, but with Al and Mg pure B is produced. The best results are obtained by electrolyzing a bath containing B_2O_3, MgO and MgF_2 kept at 1100°. 21 different borides were prepared by adding to the former baths oxides of appropriate elements. A number of oxides electrolyzed in a mixture of borates and fluorides are transformed into their elements. Zinc produced in this way can be used for reduction of WO_3 and MoO_3 added to the above baths with production of pure W and Mo. JDG(7b)

Preparation of Metal Powders by Electrolysis of Fused Salts. II. Thorium. F. H. DRIGGS & W. C. LILLENDAHL. *Industrial & Engineering Chemistry*, Vol. 22, Dec. 1930, pages 1302–1303.

Four references. The purified powder obtained by electrolysis as described in this article, has been utilized for making X-ray targets, sheet and wire by pressing, sintering and degasifying the powder in vacuo. Electrolytic thorium is extremely soft, well annealed samples having a hardness as low as D-10 on the Rockwell scale. Bars of this metal may be cold-worked to almost any extent without intermediate annealing. MEH(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Characteristics of Sprayed Aluminum Coatings. (Merkmale gespritzter Aluminium-Haufwerke.) H. REININGER. *Aluminium, Hauszeitschrift der V. A. W. Erftwerk*, Vol. 3, Jan.-Mar. 1931, pages 66–75.

Metallization of metallic as well as non-metallic materials by spraying with aluminum is eminently suitable for coatings of any thickness. To assure good adhesion, the surface of smooth materials must first be roughened either in pickling liquid or by sand-blast. The sprayed coatings can be refined and improved by thermal or mechanical treatment; the texture thus produced is of higher quality than the original textures. This refers particularly to an effective protection against corrosion and erosion; but great stresses, static as well as dynamic, are not admissible. A great number of illustrations and 9 references supplement the paper. Ha(8)

Hot Tinning Steel, Wrought, Cast and Malleable Iron Parts. CHARLES H. PROCTOR. *Metal Cleaning & Finishing*, Vol. 2, July 1930, pages 593–594.

Pure Straits Sn is preferable. When the melting point is reached in the kettle, the Sn should be covered to a depth of 1 or 2 in. with either tallow or palm oil. Flux consists of a saturated solution of $ZnCl_2$ and NH_4Cl. Steel parts are cleaned, pickled, coated with flux, and immersed in the molten Sn for 1–2 min. After removal from the Sn, they are shaken, quenched in hot H_2O or kerosene and dried. Sand-blasting is the ideal method for cleaning cast-iron. If flux does not work with cast or malleable iron, articles made of these metals should be immersed in concentrated HCl for a few moments after sand-blasting, dried by heating and immersed directly in the molten Sn. If sand-blasting apparatus is unavailable, a 15–25% HF solution at 110° F. should be used for pickling. The parts are then washed thoroughly in cold H_2O, dipped in a solution of $^1/_2$–1 part NaOH and 4 parts H_2O, washed thoroughly in cold and boiling H_2O and tinned. MS(8)

Lead Coatings on Metals Which Are to Be Cold Worked. (Ueber die Verbleiung von kalt zu verformenden Metallen.) G. DE DUDZEELE. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 205.

Improving the Appearance of Galvanized Sheets. HEINZ BABLIK. *Metal Industry*, London, Vol. 38, May 1, 1931, page 448.

There has been introduced within the last 6 months the process of coating hot-galvanized sheet with a thin layer of copper. The copper layer is thick enough to resist atmospheric attack for a long time and so protect the zinc coating. PRK(8)

Nickel-Clad Steel Plate Work. W. G. HUMPTON, F. P. HUSTON & R. J. MCKAY. *American Metal Market*, Vol. 38, Apr. 9, 1931, pages 9, 10; Apr. 10, 1931, page 10; *Mining & Metallurgy*, Vol. 12, Feb. 1931, pages 90–93.

Presented at Institute of Metals Division Annual Meeting, Feb. 1931. New product is heavy plate, $^1/_4$ to $^3/_8$ in. thick, one side coated with Ni, weight of Ni roughly 10% of entire weight, with hot-rolled steel plate finish. In making this plate relatively thick layers of steel and Ni are placed in intimate contact, heated to high temperature and rolled to finished plate. Bonding of 2 metals depends upon tendency of Ni to alloy with steel at high temperatures to form solid solutions at plane of contact. Important points are: (1) corrosion-resistant surface must be continuous; (2) all joints must be strong and prevent galvanic, or concentration cell corrosion; (3) all sheared edges must be covered; (4) rivets and other joints must be designed to prevent seepage of corrosives to the steel, even through the smallest crevices. In heating this plate for hot work it is absolutely necessary to provide fuel with low S content, not over $^1/_2$%, or else intercrystalline attack occurs, resulting in damage to Ni. DTR(8)

Spray Zincing. (Spritzverzinkung.) D. MATZINGER. *Elektrotechnische Zeitschrift*, Vol. 51, Jan. 30, 1930, page 184.

Short description of a zinc-coating plant in Holland where, in the last three years, more than 3000 tons of iron structure of all kinds have been successfully and economically treated by spraying. HA+WHB(8)

Tin-Plate Decoration and the Lacquering of Food Containers. A. L. MATTHISON. Published by the author, Birmingham, England, 1931. Cloth, $8^3/_4 \times 5^1/_2$, 135 pages. Price 12s. 6d.

This book is written in a somewhat colloquial style, and pays a good deal of attention to the products of the firm with which the author is connected, describing them by trade names only. As a maker of lacquer, the author continually points out the protective value of lacquer against corrosion by acid food products, though he does admit the danger of perforation at a crack in the lacquer. He stresses the importance of using prime tin plate, free from pin holes in the coating, and of proper cleaning before lacquering.

There are some general comments on drying ovens and many incidental observations on English and American practice in lacquering and some little information on decorative color printing. The suggested answer to many difficulties mentioned is to use some particular product of the author's firm. The preface states that the book is intended to be a useful work of reference. The reviewer would class it as an advertisement pure and simple.—

Tinning the Inside of Copper Pipe. (Innenverzinnung von Kupferrohren.) HERBERT KURREIN. *Metallwirtschaft*, Vol. 10, July 24, 1931, page 600; July 31, 1931, page 616.

The two possible methods of tinning are thermal and by electroplating. There are several objections to the thermal method, which can be done only by dipping in the case of pipe. The outside of the pipe must be treated with clay or graphite to prevent it from being tinned. Excess Sn must be removed from the inside. Due to the uneven surface and different coefficient of expansion of the two metals, cracks and porous spots may appear. Inclusions of Cu_2O will start corrosion. In earlier attempts to plate Sn on Cu long needles were formed which did not adhere firmly. Schlotter developed a plating solution containing phenolsulphonic acid and bivalent Sn which can be used at 20° C. and forms a continuous, well adhering, non-crystalline deposit. It is used with 1–2 amps. dm.^{2}, but can be used up to 10 amps. The Sn anodes go into solution at the same rate as Sn is deposited from the solution and the throwing power is good. In plating pipe, inside anodes must be used, held in place by wooden or hard rubber insulators. Current is chosen according to the diameter of the pipe and agitation of the bath is necessary. Pipe can be plated inside only or inside and outside. The process is easy to control and is cheaper than the thermal process. CEM(8)

Zinc Coating of Iron and Steel. Report of Sectional Committee, A. S. T. M. J. A. CAPP, Chairman. *Preprint* No. 28 for June 1931 meeting *American Society for Testing Materials*, 3 pages.

The Committee has requested the A. S. T. M. to withdraw from its publications the proposed specification for zinc-coating on iron and steel sheets published, as information, in 1929. Brief progress reports are given on the work of sub-committees. These committees are mostly joint ones, and their reports are abstracted under other headings. HWG(8)

INDUSTRIAL USES & APPLICATIONS (9)

International Coöperation in Aircraft Materials. Correspondence from A. PORTEVIN, Paris, France. *Metal Progress*, Vol. 19, Mar. 1931, pages 85–86.

The writer reports on studies of the International Congress in Paris toward the production of safer aircraft. WLC(9)

Electron Metal in Aeronautics and the Europa Rundflug. (Ueber Elekronmetall im Flugzeugbau und Europarundflug 1930.) J. RUHRMANN. *Zeitschrift für Metallkunde*, Vol. 22, Sept. 1930, pages 317–318.

The importance of the new methods for welding Mg is stressed. Due to satisfying properties of the welding joints and of the corrosion resistance, brass tanks formerly used could be replaced by electron metal tanks. The developments of plastic deformation methods, is considered, resulting in an increased utilization of electron sheets, profiles, tubes, etc., and the quality of electron castings is dealt with. The results of the Europa Rundflug with respect to the application of electron are discussed in conclusion. EF(9)

Use of Aluminum in the Electrical Industry. (L'impiego dell 'Aluminio nell' Industria Elettrica.) C. PRAMAGGIORE. *Metalli Leggeri*, Vol. 1, Mar. 1931, pages 109–128.

Discussion of virtues of Al conductors as against Cu, of insulation by oxide films, description of switches, transformers, electrolytic condensers, rotors, light reflectors, etc. HWG(9)

On Rope Wire. J. M. ROBERTSON. *Royal Technical College Metallurgical Club Journal*, Glasgow, No. 7. 1929–1930, pages 20–31, 14 figures, 9 references.

Internal wear and corrosion are more serious than external wear in producing failure of wire rope. Failure, in which the wires of the strand break one by one, is not a simple problem in fatigue failure. The most important property of wire for rope is the shape of the stress-strain curve. Cold drawing of patented wire without any heating for stress release gives a curve with no elastic range, the apparent proportional limit being extremely low, so that elastic and plastic deformation can take place simultaneously when the wire is spun into rope. The wire then bends evenly into place. Material with a steep stress-strain curve or with a definite yield point does not work so well, the first taking too high stress to deform it, the second yielding in steps. A solid diagram is shown for effect of time and temperature on tensile strength of wire. HWG(9)

Reduction of the Weight of Columns for Steel Building Structures. (Verringerung des Konstruktionsgewichtes von Säulen für Stahlskelettbauten.) B. BAUER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 30, 1931, pages 687–688.

If the carrying capacity of the concrete is taken into consideration, great savings in weight and cost of steel skeletons of buildings can be effected. Too frequently this phase is neglected. The result is an excess of steel, sometimes as great as 80%. A method of eliminating this waste is advanced. Ha(9)

Aluminum and Its Alloys in the Construction of Mobile Material for Railways, Street Cars and Busses. (L'Alluminio e la sue leghe nella costruzione del materiale mobile per Ferroyie, per Tramvie e delgi Autobus.) M. HUG. *Metalli Leggeri*, Vol. 1, Apr. 1931, pages 167–174.

General comment on improvement in ratio of useful weight to dead weight through use of light alloys. HWG(9)

Progress in Aircraft Material Development. J. B. JOHNSON (Army Air Corps, U. S. A.). *Aviation*, Vol. 30, Jan. 1931, pages 40–42.

Excellent summary of uses of various metals and alloys for different aeroplane parts. Steel and light alloys for wings. Welded truss-type fuselages. Heat treatment made after all welding in every case. Material has tensile strength of 150,000 lbs./in.^{2} For built-up sections extruded and rolled shapes of Al alloys are best, with special heat treatment, followed by cold working. Riveting followed by heat treatment is only satisfactory method for joining duralumin type alloy. For wing covering corrugated and flat Al alloy sheet. Heat treated Al alloy castings of tensile strength of 30,000 lbs./in.^{2} and 6% elongation give long life, average 5 years. Most satisfactory corrosion resistant steels contain 18% Cr and 8% Ni. For fuel, water and oil lines Cu is used. High price of Mg alloy castings has retarded their development. DTR(9)

Light and Ultra-Light Alloys and Their Use in the Automobile Industry. (I Metalli leggeri ed ultraleggeri e la loro applicazione nell' automobilismo.) G. GUIDI. *Metalli Leggeri*, Vol. 1, Apr. 1931, pages 163–166.

A paper presented in Jan. 1922 to the Academy of Science in Turin, but stated by the editor of the journal to contain much of present interest in regard to the Mg base alloy, "Lepto," used for pistons. The composition of this is not given, save that it contains Al and Zn. Greater power at high speeds is claimed for Mg pistons. HWG(9)

Thin Plates in Peace and War. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 18, Dec. 1930, page 86.

The writer reports experience with sheet and plate for protective purposes and gives the essential properties of useful armor. WLC(9)

Stainless Steels Used in Heavy Machinery. CHARLES E. HERD (Montreal Engineering and Machine Works). *Metal Progress*, Vol. 19, Jan. 1931, pages 44–49.

The author describes the application of stainless steel to paper mill machinery and hydraulic turbines. WLC(9)

Traveling Cranes Built of Aluminum Alloy. E. G. HARTMANN. *Power*, Vol. 73, Mar. 31, 1931, pages 518–519.

Tool Steels in the Ceramic Industries. H. L. HARRISON. *Ceramic Age*, Vol. 16, Dec. 1930, page 321.

Points out the advantages of high grade alloyed steels for use in dies or liners in the manufacture of bricks and tile and describes a few suitable steels. Ha(9)

Aluminum Alloys with Special Reference to Alclad. (Aluminiumlegierungen, insbesondere Alklad.) P. M. HAENNI. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 205.

Brief reference to a paper read at the International Congress of Mining, Metallurgy and Applied Geology, Liege, 1930. See "Results Obtained with Aluminum in Construction of Street Cars and Railway Coaches," *Metals & Alloys*, Vol. 2, July 1931, page 131. EF(9)

Metals for Coins. GUICHARD, CLAUSSMANN & BILLON. *Iron Age*, Vol. 126, July 24, 1930, page 216.

Presented to the Académie des Sciences, Paris. This is a brief abstract translation, being an investigation of the limit of hardness obtainable with certain metals for making coins and medals by stamping. With a reduction of about 76% Ni, and a Cu alloy with 8.8% Al showed greatest degree of hardness. These were followed by bronze of 94% Cu, 4.6% Sn and 1.4% Zn and by Au 90% pure. VSP(9)

Art-Craft Welding. (Kunstgewerbliche Schweissarbeit.) FUECHSEL. *Autogene Metallbearbeitung*, Vol. 24, June 1, 1931, pages 164–167.

Description of various methods of obtaining artistic effects in metal working. Photographs illustrate the many possibilities in ornamentation. Ha(9)

Light Alloys at the Twelfth Aeronautical Exposition. (Les alliages légers au XIIe salon de l'aéronautique.) DOUCHEMENT. *Revue de Métallurgie*, Vol. 28, Apr. 1931, pages 185–193.

Practical advantages of the application of light alloys to airplane and automobile constructions are pointed out. Usually duralumin type heat treated alloys are used. Their usual characteristics: elastic limit 24–28 kg./mm.², tensile strength 40–45 kg./mm.² and elongation 16 to 20%. Often the metal is protected by a layer of pure aluminum rolled on it, as in Vedal process. Protection produced by it is satisfactory because electrolytic action prevents any attack of the base as long as any Al still remains. JDG(9)

Selection and Heat Treatment of Gear Steel. E. F. DAVIS. *Fuels & Furnaces*, Vol. 8, Oct. 1930, pages 1341–1348, 1385.

Gear steel must contain a minimum amount of inclusions. If these are of microscopic size and will disseminate, they lessen the number of gears per grind, dull the cutter rapidly and produce minor ridges and roughness on the gear tooth. In large segregates, they cut a groove in the cutter. Grain size must be uniform, a fine grained steel being preferable because of the higher impact and fatigue values. Content of C is usually within the 0.5% range. Steels used are of 2 classifications—oil-hardening grade and carburizing grade. Gives the chemical composition and describes the physical characteristics of the individual automotive gear steels which make them suitable for a particular kind of service. Outlines heat treatment necessary to produce the best results. Most popular oil-hardening steel is SAE 5150 with 0.48–0.52% C and 0.88–1.10% Cr. The best oil-hardening steels are SAE 2345 and SAE 2350, containing 3½% Ni and 0.40–0.55% C. They are highest in impact value, although not higher in physical values nor fatigue properties. Most extensively used gear steel is 3½% Ni steel. This carburizes at 1650° F. Best of all gear steels is 5% Ni steel. It is the highest in impact value, strength and fatigue properties. MS(9)

A New Cap for Steel Flasks. (Eine neue Stahlflaschenkappe.) W. GELDBACH. *Die Schmelzschweissung*, Vol. 9, Apr. 1930, pages 83–84.

This new cap is made so that it will unscrew easily and so it is not necessary to damage the flask to get it off. It also serves as a wrench for the valve. Ha(9)

Welding Technique in the Building Trade. (Schweisstechnik im Baugewerbe.) H. JUERGENS. *Die Schmelzschweissung*, Vol. 9, Sept. 1930, pages 207–209.

A few samples of doors, gratings and similar parts as used in the building of dwellings. Ha(9)

Steel Castings as Machine Parts. R. A. BULL. *Machine Design*, Vol. 3, Apr. 1931, pages 36–39.

The difficulties of casting pieces in steel due to the high shrinkage are discussed in the case of the structural texture shown in micrographs. A principal requirement for a good casting is that it should have as much similarity in respect to the thickness of every member as the conditions of use permit. Great care and, often, considerable expense must be used in mold construction to secure uniform cooling of the casting. Ha(9)

Aluminum in the Decorative Arts. (L'Alluminio nell 'Arte Decorative.) S. BRUNELLI. *Metalli Leggeri*, Vol. 1, Mar. 1931, pages 97–108.

Profusely illustrated description of modern architectural and decorative use of Al. HWG(9)

Development of the Drop-Forged Metal Propeller. FRANK W. CALDWELL. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 2, *Aeronautical Engineering*, pages 73–76.

The author tells of various types of metal propellers for airplanes, and their advantages and disadvantages. These include a tubular type, a type built up of various structural members riveted or welded together, the plate type and the drop-forged type which is the latest development. Hollow blades of aluminum alloy suitable for drop forging are used. The weight of these is slightly more than similar wooden propellers and the limit of life has not yet been established. (9)

Aluminum and its alloys. (L'Alluminio e le sue leghe.) F. LIBERA. *Metalli Leggeri*, Vol. 1, Jan.-Feb., 1931, pages 19–28.

Very general, rather non-technical article, illustrated by photographs of some applications to transportation architecture, etc. Several photos are shown of mosaics of porcelain and aluminum. HWG(9)

Application of Light Alloys in Naval Construction. (Note sulla possibilità di applicazione delle leghe leggere nelle construzioni navali.) C. PANSERI. *Metalli Leggeri*, Vol. 1, Mar. 1931, pages 83–95; Apr. 1931, pages 143–161. 104 references.

General discussion of desirability of weight-saving in naval construction and importance of avoidance of corrosion in light alloys for this purpose. The work of Baumeister on the "KS sea water" type alloy is quoted. According to Sterner-Ranier, this alloy has a "theoretical" composition of 2½% Mg, 2½% Mn, 0.2% Sb, balance Al. The treatment of Al alloys with Cl_2, N_2, BCl_3 or $TiCl_4$ to produce greater soundness and smaller grain size is discussed, with the idea that these may lead to better corrosion resistance. Alclad, paint, varnish and bitumastic protective coatings, anodic oxidation, the Jirotka process for putting on a surface film, aluminum paint coatings, etc., are discussed. The structural properties and strength-weight ratios of many alloys are given to show the value of the light alloys. The fatigue properties are tabulated. Corrosion-fatigue is briefly discussed. Applications of Al alloys to naval purposes are discussed and illustrated. HWG(9)

Magnesium and Hollow-Steel Propellers. G. T. LAMPTON (Hamilton Standard Propeller Corp.). *Preprint* for May 1931 meeting, Aeronautic Division, *American Society of Mechanical Engineers*. 7 pages.

The endurance limits of propeller alloys are: heat-treated duralumin 12,000 lbs./in.²; magnesium alloy 10,000; Cr Mo steel of 200,000 tensile 90,000. On the endurance-density basis, the 3 are in the approximate ratio 1:1¼:2⅔. The problem is to fabricate the last 2 so as to hold down weight, and get the benefit of the higher endurance ratio. The Mg alloy with 4% Al, ½% Mn is now being forged satisfactorily, and makes a lighter propeller than dural, and shows up better on whirl tests. A new method of making hollow steel propellers starts with cold-drawn seamless tubing which is tapered and thickened over the tip half by swaging, then annealed and elongated on a mandrel. The tube is then turned to the proper thickness in wall taper, the tip heated and closed by spinning. The closed end tube now has the proper circumference and wall thickness at each point, but is of circular cross section. Squeezing the tube into blade shape is then done by heating to 1650° F. and pressing it between high test cast iron dies while 300 lbs. air pressure is forced into the tube. The formed blade is then reheated, and again placed in the dies, now touching the dies at all points at once, instead of progressively as in the forming. Air pressure is again applied. Thus, the blade is "die quenched," and remains true, without warpage. The 4130 X steel, thus quenched to 440 Brinell is then tempered slightly, to around 400 Brinell, and chromium plated. Nitriding is also being considered. This gives a wear resisting blade. A 13 ft., 3 bladed propeller weighs 140 lbs. against 260 lbs. for duralumin. Magnesium propellers show weight and performance advantages over duralumin in all sizes, and in the larger sizes, the hollow steel has a decided advantage over magnesium. HWG(9)

Aluminum Alloys Used in Commercial Motor-Vehicles. Discussion of FRANK D. GOLL's Transportation Meeting Paper. *S. A. E. Journal*, Vol. 28, Feb. 1931, pages 215–217.

Discussion of Al for commercial motor-truck bodies and tanks. Statement that commercially pure Al is seldom used for structural parts except when alloyed with another element or elements such as Cu, Mn, Mg or Si. Comments upon new alloys availab e. Author considers subjects of design, selection of a correct Al alloy for a particular purpose and like matters. Advantages of Al bodies as to weight saving, low maintenance-cost, residual value and better appearance, are stated also, as well as special advantages applicable to certain types of body now in operation. Paper also treats Al motor-truck tanks and presents numerous statistical data in tabular form. Comments on the methods of fabrication, shop practices and design values are made in the discussion, and upon the relative cost of Al and of steel fabrication. Experience had with tanks is stated by two discussers, and some of the factors relating to fabrication costs are enumerated. Weight saving is brought out as a major factor that the tire manufacturers are dependent upon, and some further possibilities of saving weight are mentioned. Experience of one manufacturer of Al bodies is stated. See also *Metals & Alloys*, Vol. 2, April 1930, page 81. MFB(9)

Nickel Alloy Cast Iron in Automobile Industry. (Nickelgusseisen im Automobilbau.) H. OSTERMANN. *Deutsche Motorzeitschrift*, Vol. 7, July 1930, pages 340–350, 15 references.

Requirements to be met with by casting material for cylinders as strength, resistance to wear, machinability, absence of internal stresses. Properties of (a) cast iron, (b) alloyed cast iron. Influence of Ni and Ni + Cr additions upon quenching strains, specific gravity, resistance to wear, thermal expansion. Application of Ni-alloyed cast iron. EF(9)

Chromium as a Printing Surface. GEORGE B. DRACH (Jersey City Printing Co.) & LOUIS WEISBERG (Weisberg and Greenwald). *Metal Industry*, N. Y. Vol. 29, May 1931, page 195.

Abstract of paper read before the American Society of Mechanical Engineers, March 16–17, 1931. A half-hour chromium deposit on printing surfaces holds up for as many as 1,800,000 impressions without requiring repairs or refinishing. PRK(9)

Light Iron and Wire Products. JAMES CLARK. *Welding*, Vol. 1, Aug. 1930, pages 691–692.

Describes some methods and shapes for ornamental work. Ha(9)

Lautal as New Material for Oxygen Flasks. (Lautal als neuer Werkstoff für Sauerstoff-Flaschen.) N. CHRISTMANN. *Schmelzschweissung*, Vol. 9, Dec. 1930, pages 277–281.

The manufacture of lautal-flasks is described and the government specifications (German) for guaranty tests are cited; the test methods are described and test results given. Ha(9)

Rayon and Nitric Acid Use Italy's Aluminum. Correspondence from F. GIOLITTI, Turin, Italy. *Metal Progress*, Vol. 20, Aug. 1931, pages 85–86.

The writer describes chemical applications of pure aluminum and light alloys in Italian industry. WLC(9)

An All-Metal Savoia. R. GIACOMELLI. *Aircraft Engineering*, British, Vol. 3, July 1931, page 174.

A metal version of the famous Savoia S. 55 twin hull seaplane has been constructed, and as a result an interesting comparison between wood and metal construction has been obtained. The metal seaplane, precisely the same in all respects, including equipment, as its wooden prototype, has effected a saving in weight of 1777 lbs. with a factor of safety of 9 as against 7.4. The S. 55 M is a torpedo-carrying machine, with two floats, a full cantilever plane with two engines mounted in tandem on a gantry above the center section. The whole structure is metal, constructed of rolled aluminum alloy strip with duralumin sheet plating. WAT(9)

Railroad Makes Brass Trolley Wheels. C. W. GEIGER. *Brass World*, Vol. 27, July 1931, page 157.

The Market Street Railway Co., San Francisco, Cal., build their own trolley wheels. They are doing 18,000 miles and better. A brief illustrated outline of the manufacture is given. WHB(9)

Manufacture and Testing of Steel Flasks According to Police Regulations for Liquified and Compressed Gases. (Die Herstellung und Prüfung von Stahlflaschen nach der Polizeiverordnung für verflüssigte und verdichtete Gase.) ALEX MATTING. *Die Schmelzschweissung*, Vol. 9, Oct. 1930, pages 232–236.

The great economy in transportation of gases by liquefying and compressing has created a great demand for steel flasks which are used in almost all countries for this purpose. The different methods of manufacturing the steel flasks from seamless tubes or hollow blooms or ingots by the Mannesmann, Pilger and Everhardt processes are discussed and the respective advantages pointed out. The flasks have, usually a diameter of not more than 210 mm. and a length of 2 m. and are, in all countries, subject to certain guaranties. In Germany, a material of more than 41 kg./mm.² tensile strength and an elongation of 12% for 100 mm. test length is required. The testing methods are described in detail, extending not only to the material of the flask but also to the gases with which the flask is filled. Comparative data for England, America, Switzerland and Japan are given. 7 references. Ha(9)

Vanadium in Iron Industry. (Das Vanadin in der Eisenindustrie.) PETINOT. *Korrosion und Metallschutz*, Vol. 6, Sept. 1930, page 207.

Briefly refers to the paper read at the International Congress of Mining, Metallurgy and Applied Geology, Liege, 1930. See "Vanadium Additions Improve Steel," *Metals & Alloys*, Vol. 2, Aug. 1931, page 154. EF(9)

Dependability in Propellers. RAYCROFT WALSH. *U. S. Air Service*, Aug. 1931, pages 36–37.

The author is president of the Hamilton Standard Propeller Corporation. The article is a brief survey of the development and tests of aircraft propellers. Metal propellers are subjected to a so-called whirl test, usually of 10 hours duration at 300% overload of rated capacity. In one case an entirely new design of a new metal successfully withstood 600% overload on the whirl test. In the old wooden propeller a 50% overload was considered ample. A considerable number of standard type propellers have been flown more than 2500 hours in commercial service. Tests at Wright Field now in progress and incomplete indicate so far that long use shows no loss in strength. Experience has shown that the early removal of nicks and careful periodic inspection by a trained personnel is very essential, for fatigue failures often start from a very small nick or scar on the surface of the blade. The present stabilized design is about to give way to really important propeller developments involving greatly increased efficiency and much lighter weights. Forced magnesium and hollow steel propellers will permit the general adoption of the large propellers required for geared motors, with their consequently increased cruising efficiency. When these blades are used in a controllable pitch propeller, the last obstacle will be removed to the use of geared motors. When the blades of these propellers are turned to the low pitch position, the unfavorable take-off characteristics inherent to the use of geared engines can be changed into a marked improvement over the take-off obtained with direct-drive motors. WAT(9)

The Use of Special Non-ferrous Metals and Alloys in Marine Engineering and Shipbuilding. J. W. DONALDSON. *Metallurgia*, Vol. 4, July 1931, pages 77–80.

Non-ferrous alloys are used in ship construction on account of their resistance to corrosion. Alloys for condenser tubes, turbine blades, engine parts and their uses are discussed. 4 references. JLG(9)

A New Coinage Metal, Forgery Detected Without Analysis. M. CHIKASHIGE & S. UENO. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 61–64, 5 figures.

Heat-treatable alloys of 63–71% Ag, 28–36% Zn, and 1/2 to 5 1/2% Cu are doubled in hardness by quenching. Depending on composition the quenching temperature ranges from 650° to 240° C. Part of the ternary equilibrium diagram is shown. These are suggested for coinage. Heat treatment and hardness determination of a suspected coin would show whether it was of the coinage composition or not. HWG(9)

Aluminum Casting for Diesel Motors. (Aluminiumguss in Dieselmotorenbau.) W. HARTL. *Automobiltechnische Zeitschrift*, Vol. 34, Feb. 16, 1931, pages 94–98.

The heavy cast parts of Diesel engines may be replaced by lighter aluminum alloys on the following principles: The alloy involved shall possess good casting properties. The amount of shrinkage shall be sufficiently low to prevent the formation of cracks during solidification. The alloy shall be tough at higher temperatures. The engine parts having a direct contact with cooling water and combustion gases shall be corrosion-resistant. Owing to lower E-modulus, impact and fatigue value of aluminum alloys, the rigidity of engine parts shall be increased by proper design. Ample space is devoted by the author to this question and stress diagrams are drawn for various designs. Silumin or its derivative containing 0.8% Cu and 0.3–0.6% Mn seems to meet most of the cited requirements to a greater degree than other aluminum alloys. Also, aluminum alloys containing more than 1% Cu and Zn can be used but not in parts exposed to casting water or combustion gases. ER(9)

Nirosta and the Chrysler Building. (Nirosta und Chrysler-Bebäude.) SCHARSCHMIDT. *Krupp'sche Monatshefte*, Vol. 12, May 1931, pages 112–117.

The article gives an illustrated description of the application of Nirosta in building construction and deals with its use in some cases of modern structures in the United States and in Germany. GN(9)

The Use of Nickel as a Catalyst for Hydrogenation. HOMER ADKINS & HOWARD I. CRAMER. *Journal American Chemical Society*, Vol. 52, Nov. 1930, pages 4349–4358.

The preparation of a reasonably active nickel catalyst is described and experimental details are given for the satisfactory reduction of 45 representative organic compounds. MEH(9)

The Life of Metallic Tubing Subjected to Vibration. R. L. TEMPLIN. *Automotive Industries*, Vol. 65, July 11, 1931, pages 50–52.

Metallic tubing such as is used for air, gas and oil lines in airplanes, automobiles and other machinery must frequently withstand vibrational stresses under the service conditions imposed. The magnitude of the stresses caused by vibration under service conditions is rather difficult to evaluate It must be emphasized that the designer of a structure or machine involving the use of such tubing is to a large extent responsible for the proper installation of the tubing so that it will be subjected to a minimum amount of vibration during service, and if vibration occurs, the resulting stresses will be as small as possible. Many of the vibrational failures noted in the past can be directly traced to improper design of the supports or fastenings applied to the tubing. (9)

Applications for Metallic Gaskets. F. W. SYLVESTER. *Heating, Piping & Air Conditioning*, Vol. 3, June 1931, page 472.

A type of metallic gasket which appears to be particularly useful in making up joints with flanges that are not quite true is the corrugated metal gasket made up of a single sheet of metal with the corrugations on both sides filled with asbestos cord. This type of gasket has been successful in marine oil pumping systems where the working pressure has been 750 lbs./in.^{2} WAT(9)

Strong Steels for Bridges. D. B. STEINMAN. *Metal Progress*, Vol. 19, June 1931, pages 33–39.

The author outlines the service the bridge designer expects of the metallurgist in the way of dependability, high strength, low cost steels. Applications of various alloy steels are illustrated and discussed. Properties of the common high strength steels used are tabulated. Comparisons of cost of several materials are made. Fifteen considerations for the metallurgist and bridge designers are listed amongst which are high strength, freedom from fabrication difficulties, uniform dependability and coöperation in the design of the newer and larger bridges. WLC(9)

Pennsylvania Adopts 152-lb. Rail. T. J. SKILLIMAN. *Railway Age*, Vol. 91, Aug. 8, 1931, pages 205–206.

The author is chief engineer, Pennsylvania Railroad System. The demand for greater stiffness and longer life under increasing axle loads and higher speeds are met by the design of this heavy section. The first heats were laid in May and June 1931 on the New York Division between New York and Pittsburgh. The object of this design is to satisfactorily and safely withstand an axle load of 100,000 lbs. moving at a speed of 100 miles per hour. This contrasts with an axle load of 80,000 lbs. moving at a speed of 80 miles per hour which was the service for which the 130-lb. rail was designed that has been standard on the Pennsylvania since 1916. The height is 8 inches (1 3/8 inches higher than 130-lb. rail). It is estimated that this change in design will meet the speed and loading requirements for the next 25 years. A definite desirable ratio of the perimeter of each part of the rail, that is, the web and the base and the head, to their respective volumes, so that the rate of cooling of all of these parts should be as nearly even as possible, in order to minimize the creation of internal stresses as a result of cooling. A provision is made for canting the rail, and that this should be done in the ratio of 1:40 by the use of a canted tie plate, as a further means of insuring a better contact between head of the rail and the tread of the wheel. WAT(9)

Seamless Steel Tubes for Aircraft. AUSTYN REYNOLDS. *Aircraft Engineering*, British, Vol. 3, June 1931, pages 141–145.

The article is a description of the manufacturing processes employed in the Reynolds Tube Company, Ltd., and describes the materials and their qualities. A new machine for proof bend testing of tubes is described and illustrated. WAT(9)

Applications of Stampings in Aircraft Construction. H. G. RUNDE. *Metal Stampings*, Vol. 3, July 1930, pages 637–638.

From paper read before the American Society for Testing Materials, June 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. MS(9)

Developments in the Manufacture of Lead-Covered Paper-Insulated Telephone Cable. J. R. SHEA. *Bell System Technical Journal*, Vol. 10, July 1931, pages 432–471.

All the various stages of manufacture are discussed. The sheathing of the cable and the melting of the PbSb alloy are briefly but interestingly described. HWG(9)

The Application of Steel Pipes as Structural Parts for Automobiles. (Die Verwendung von Stahlrohr im Automobilbau.) W. REINECKE. *Automobiltechnische Zeitschrift*, Vol. 34, Jan. 10, 1931, pages 11–13.

The introduction of front wheel brakes implies a need for new design of front axle, which will resist the torsional stress better. The tube front axle would meet this requirement adequately. According to stress diagram, the torsional strength of tube axle of 4.43 and 11.12 cm.^{2} in cross section would be 9 and 24 times higher than that of double-T-axle of equal cross section. The wide application of tube front axle has been restricted by not having at hand the proper economical ways of fixing spindle arm and spring clips to axle. The tube-frames, as employed by Tatra, Austro-Daimler, Faudi and Harris Leon Laisne cars, may also find a wider use. The standard U-frame system does not possess sufficient diagonal strength; this can be overcome by the use of tube-frames. The recent state in development of welding technique would supply cheap and simple means of joining separate tubes together into a rigid frame system. ER(9

Aluminum Busbars Resist Power Arcs. J. D. PORTER. *Electrical World*, Vol. 98, July 18, 1931, pages 104–105.

Experiments indicate that the aluminum arc is comparatively unstable and does less damage to the aluminum surface because of the arc's lack of concentration. Illustrations are shown of Al and Cu busbars tested under power arcs. WHB(9)

A New Weld-Flange Joint for Gas and Water Pipes. (Eine neuartige Schweiss-Muffenverbindung für Gas- und Wasserleitungen.) E. KALISCH. *Die Schmelzschweissung*, Vol. 10, May 1931, pages 108–109.

A flange with a long collar which is filled with packing to about 1/2 or 2/3 and then the outer part bent down over an iron ring packing and welded. Tested from a welded-on outlet by high pressure (50–80 atmospheres) the strength and tightness can be easily proved and at the same time the packings are pressed together very tightly. Ha(9)

Construction and Manufacture of Steel Wire Rope. G. C. HODGSON. *Canadian Mining & Metallurgical Bulletin* No. 231, July 1931, pages 816–821.

The range in the composition of steel used in the manufacture of wire rope is carbon 0.4–0.9%, Mn 0.4–0.8%, S not over 0.04%, and P not over 0.04%. Specifications for physical tests are also given. Crucible cast steel, extra-strong crucible cast steel (mild plow), best plow and best improved plow are used (order of increasing tensile strength). AHE(9)

85,000 Chromium-Plated Gages Used in Ford Plant. C. O. HERB. *Machinery*, Vol. 37, July 1931, pages 817–821.

The engineers of the Ford Motor Co., Dearborn, Mich., conducted an extensive investigation into the advantages obtainable by using gages plated with chromium. When it was found that in certain grinding operations, chromium plated gages could be used 218 hours, as against 4 hours for tool-steel gages, it was decided that chromium-plated gages should be used whenever possible. The manufacturing departments had to be sold on this idea, but the results of hundreds of tests were convincing, and the practice has now been followed with complete success for more than two years. Furthermore, it has been adopted in all plants of the company. The Ford Motor Co., therefore, chromium-plated gages to lengthen their life, and thus substantially lower inspection costs. The gage wear limit has been established as 20% of the difference between the minimum and maximum dimensions. For example, if the specified tolerance on the part is 0.002-in., the wear limit on the gage would be 0.004-in. The most important economy effected by the adoption of chromium-plated gages has been in inspection costs, which have been reduced, in many cases, one-half and in some instances even more. The greatest savings have been made on applications where the specified part limits are close. (9)

Crane Built of Strong Aluminum Alloy. F. V. HARTMAN & E. C. HARTMAN. *Iron Age*, Vol. 125, June 5, 1930, pages 1689–1690; *Metallurgist*, July 1930, pages 99–100.

Describes a 10-ton Al traveling crane of the United States Aluminum Co., Massena, N. Y. It is a 3-motor single-hook crane with a lift of 22 ft. The girders of Al alloys, have a span of 72 ft. 2 in. The Al alloy girders were constructed with section deeper, wider and of greater sectional area, due to the difference in modulus of elasticity between Al and steel. Compares Al crane with a steel crane. See *Metals & Alloys*, Vol. 1, July 1930, page 630. VSP+VVK(9)

New Airships Use Stronger Metals. JOHN F. HARDECKER. *Metal Progress*, Vol. 20, July 1931, pages 37–44.

Development of light strong alloys for airship applications are described and properties given and discussed. WLC(9)

Recent Progress in the Industrial Application of Alloy Steels. R. HADFIELD. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 1–24.

Account of the achievements of Hadfield and his firm. What little actual data are given refer to trade-named steels. HWG(9)

Dimensional Changes in the Manufacture of Electrotypes. N. BEKKEDAHL & W. BLUM. *Bureau of Standards Journal of Research, Research Paper* No. 308, Vol. 6, May 1931, pages 829–845.

The different operations in the electrotyping process produce the following changes in dimension and must be controlled accordingly to produce plates with uniform dimensions. 1. Molding. Wax molds are almost exactly the same size as the originals. Lead molds are slightly larger (about 0.05 per cent) than the originals. No special precautions are required to produce uniform plates by either method of molding, but plates made by the two methods are not likely to match each other exactly. 2. Depositing. When copper shells are deposited from cold solutions there is a slight contraction (about 0.05 percent). The use of warm solutions at a high-current density produces the desired hardness with no appreciable change in dimensions. Nickel-copper shells always contract by about 0.15 percent. This value is not affected by increasing the thickness of copper and nickel. Such a change in thickness does, however, materially affect the stretch in curving. It is therefore important to keep the conditions for nickel and copper deposition constant, and to produce shells of uniform thickness and strength. 3. Casting. Casting always causes a shrinkage of about 0.15 percent, which is not much affected by the temperature of casting or the rate of cooling. Any large change in composition of the electrotype metal will affect the shrinkage. Shrinkage is decreased by increasing the thickness of the shells. 4. Finishing. Hand finishing always stretches the plates, by amounts that vary with the extent of the finishing operation. Straightening under pressure at ordinary temperature also stretches the plate, but more uniformly than does hand finishing. Straightening in a hot press causes a contraction of about 0.10 percent. 5. Curving. The stretch of plain plates in curving is usually less than that calculated from the formula for a homogeneous plate; and a type form stretches more than calculated. Hot curving may produce a slightly greater stretch than cold curving. With a given method, most uniform results are obtained when the shells are of the same thickness and strength and have the same type of pattern, and when the electrotype metal is of the same composition. The temperature of casting and rate of cooling of the electrotype metal have little, if any, effect on the stretch in curving.

In curving by the "nonstretch" method, it is possible by adjusting the thickness of metal cast upon the face of the plate to reduce the stretch to approximately zero. If too much metal is applied, shrinkage may be produced in curving. WAT(9)

HEAT TREATMENT (10)

Effects of Prequench Treatments on the Hardness, Body and Structure of Hardened Tool Steel. R. H. HARRINGTON (General Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 404–422.

Paper presented before the Twelfth Annual Convention of the Society. Includes discussion. The paper is illustrated with 7 charts and 18 micrographs. Body is defined as the ability of steel to take repeated quenching without failure. The difficulties in the treatment of small dies in quantity were the subject of this study. To obtain the best results a pre-quench treatment is recommended. For maximum hardness an air-normalize from 900° C. (1650° F.) followed by water-quench from 800° C. (1470° F.) and a draw from 200° C. (390° F.) is recommended, for maximum body an anneal from 750–800° C. (1380°–1470° F.) followed by water quenching from 750° C. (1380° F.) and for combination of high hardness and good body an oil quench from 850° C. (1560° F.) is recommended. In discussion G. V. Luerssen, Carpenter Steel Co., mentions the inherent characteristics of the steel as related to body and suggests the study of the body of steels of widely different characteristics. S. L. Hoyt, General Electric Co., states that body increases with the percent Swedish iron in the crucible charge, with the time of working, and with decreased size of melt. WLC(10)

Heat Treating Gears Made of Armor Plate. ROBERT E. BULTMAN. *Metal Progress*, Vol. 19, May 1931, pages 70–74.

The author discusses the machining properties and heat treatment of the Krupp steel of 1.20–1.70% Cr, and 3.80–4.30% Ni for carburizing. Due to toughness, special treatment is necessary to make the material machinable. Service results have shown that in spite of the added cost of the treatment its use is justified in heavy duty trucks and busses. Application of 5% Ni carburizing steel to truck transmission gears is also discussed. WLC(10)

Practical Considerations on Hardening. (Praktische Härtereifibel.) V. FABIAN. V. D. I. Verlag, Berlin, 1930. Paper, 6 × 8¼ inches, 92 pages. Price 5 RM.

This is an attempt to describe to non-technical workmen the proper methods of hardening tool steels. Fabian states that whatever its chemical composition, when a steel specimen reaches its own transformation temperature, blisters appear to rise up on its surface, and that this phenomenon and the correct hardening temperature coincide. Throughout the book, the statements made are of about the same order of accuracy.

Fracture tests are described and crude sketches of fractures given, by which to determine with what sort of tool steel the blacksmith is dealing. Spark tests are briefly described. Martensitic and other structures are referred to quite often, but are not illustrated, save by sketches showing where hardened zones will occur, and are not described sufficiently for the non-technical reader to get much of an idea of them. Hardening and drawing temperatures are often referred to in degrees, but it is obvious that the the author would be surprised if his readers had a pyrometer. He does urge them to familiarize themselves with some hardness tester.

A good many practical kinks as to suitable precautions to avoid distortion and cracking are given. The suggestions are based on good scientific bases, but it is hard to see how a workman could be expected to get good results without closer control of temperature than he would be able to apply if he is working in a shop as badly handicapped by the lack of pyrometers as the type of shop the author seems to be writing the book for. The book would have been of some value to the average heat-treater if he had only the equipment of 25 years ago. It would not be particularly helpful to workmen in modern plants.

One gathers that glycerine is a fairly common quenching medium in small German hardening rooms, as it is often mentioned as an alternative to oil.

Heat Treatment Determines Properties of Manganese Steel. HARRY P. EVANS. *Steel*, Vol. 87, Sept. 11, 1930, pages 66, 68.

Abstract of paper read before the American Foundrymen's Association. Explains mechanism of changes which confer special properties on manganese steel. Low manganese steel, if properly treated, will give physical properties comparable to more complex alloy steels. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 900. MS(10)

The Machining of Stainless Steel. R. WADDELL & F. WORTON. *Aeroplane*, England, Vol. 40, Apr. 29, 1931, pages 784, 786, 788, 790; *Machinery*, London, Vol. 36, Jan. 8, 1931, pages 491-493.

An abstract of a paper read before the Institute of Production Engineers and before the Yeovil Branch of the Royal Aeronautical Society. Stainless steels contain varying amounts of Cr, generally upward of 10%. Brearley steels (martensitic) are all more or less hardened by heat-treatment and are magnetic. They are here subdivided into: (1) steels with .15–.35% C and 11.–14.% Cr, (2) steels with less than .15–.35% C and with 13.–16.% Cr, and (3) steels with less than .2% C, 16–20% Cr and 1.5–2.5% Ni. Type (1) is the cheapest on the market and offers least resistance to general corrosion, (2) steel are softer, more expensive and more resistant than (1), and (3) steels are slightly harder than (2) but softer than (1). They are much more resistant to general corrosion and particularly so toward seawater. Strauss (Krupp) steels (austenitic) are not hardened by heat treatment but are by cold work—an undesirable feature. They are non-magnetic, except in the work-hardened state. They have a low elastic range, in their normal state, but are more highly resistant to general corrosion than the Brearley steels. Some special variants withstand attack from even sulphuric acid. At present, all stainless steels are more difficult to machine than the mild steels and brass. Warpage is often encountered and is caused either by the release, on machining, of internal stress locked up in the material or by the setting up through rough machining, of differential stresses in the material. Curves show a heating and cooling curve of a low time-rate and of a quick time-rate (corresponding to hardening condition) and a comparison shows that the cooling range has been shifted to a much lower temperature (250°) and the amount of expansion greatly increased, simply by accelerating the rate of cooling. An air hardening diagram shows that the time-lag (in reaching any given temperature) between the surface and the center is not great and that the volumetric change takes place in both positions at about the same temperature. The water hardening diagram reveals a considerable time-lag between the surface and center curves and a wide divergence in the temperature at which the volumetric change takes place. Time-lag and temperature difference operate in the same direction, to produce severe internal stresses and the trouble becomes progressively more formidable with increasing dimensions of the object being hardened. Tempering relieves these to a greater or less extent. Fine finishing cuts are best for stainless steel as distorted surfaces greatly weaken the resistance of the steels to corrosion. Distortion of the surface material renders it electro-positive to the undistorted material below it. Both groups of stainless steels tend to seize or stick in sliding contact with each other, making it desirable to avoid rubbing contacts wherever possible. Conclusions drawn are: (1) cold work stresses in ordinary carbon- and alloy steels and in the martensitic stainless steels may be reduced by tempering at 550–600° and to a less extent by prolonged tempering at lower temperatures, (2) hardening stresses are least in the air-hardening steels, greatest in the water-hardening, with the oil-hardening lying somewhere between, (3) hardening stresses can be reduced or removed by tempering, (4) machine stresses can be reduced by careful centering, by the use of light cuts and sharp cutting tools, and by periods of rest between cuts. WHB(10)

Deformations Accompanying Thermal Treatment of Steel. (Nouvelles recherches concernant les déformations accompagnant les traitements thermiques de l'acier.) PORTEVIN & SOURDILLON. *Revue de Métallurgie*, Vol. 28, June 1931, pages 348–365; July 1931, pages 379–390.

Besides the usual physico-chemical and structural changes occurring in heat treatment of metals, deformations, internal straining, cracking, etc. present a new field of investigation of great interest but difficult of approach as being a function of anisothermy affected by the shape of the sample. In a previous paper (*Revue de Métallurgie*, Vol. 24, page 215) the question was approached from the standpoint of annealing and quenching. It was found that annealing reduces the length and increases the diameter of the cylindrical test pieces which is more pronounced the higher is the temperature and the faster is the cooling. The increase of diameter is more pronounced at the center than at the edges. Quenching of specimens from a temperature at which they have a considerable viscosity produces an insignificant change in their dimensions, which increases somewhat with the rise of temperature and then rapidly as soon as transformation temperature is reached both for martensitic and austenitic transformations. The former causes the changes opposite to those observed at lower temperatures while, at austenitic transformation, a contraction of both dimensions is produced which is able either to reduce, neutralize or even reverse the results of the former. In a general case, the curve has 3 branches the position of which, for geometrically identical samples, depends on the critical temperature of quenching inherent in a given steel. Knowing the shape of these curves, it is possible to harden a steel by quenching it from a temperature which will not produce any changes in dimensions when the specific properties of a steel permit it. Secondary phenomena inevitably occur during these changes more or less pronouncedly according to the energy of cooling and intervention of other factors, such as thermal conductivity of the metal, all of which affect anisothermy, becoming larger the greater is the critical quenching temperature of the alloy. Higher cooling speeds always increase the amount of deformation. The amount of strain in the metal before quenching does not have any appreciable influence. Annealing before quenching entirely eliminates the influence of any previous treatment while the time of heating for quenching has no effect whatever. Uniformity of cooling is obligatory; otherwise distortion inevitably occurs. The repetition of similar treatments causes additive dimensional changes. Drawing produces progressive transformations in the metal and its effects are additive. A rapid contraction takes place on drawing quenched specimens at 300° reaching a maximum at 600°. By drawing at the same temperature specimens hardened at different temperatures, particularly when austenitic quench was obtained, it is possible to obtain either a considerable elongation or contraction depending on whether martensitic or austenitic transformation is taking place. Some applications of these principles to the heat treatment of cluster gears and other automobile parts are given. JDG(10)

Hardening (10a)

Some Sources of Variation in Hardening Practice. H. J. FRENCH. *Houghton's Black & White*, Vol. 4, July 1931, pages 4–8.

The uniformity of hardening depends, to a great extent, on the surface of the articles to be hardened. Experiments were made to show the influence of rough surfaces on the cooling. Where possible, a separation into groups of similar articles is recommended to insure equal hardness by the same treatment. Ha(10a)

The Hardening of a Special Chrome-Vanadium Steel. (Estudio del temple de un acero especial al cromo-vanadio.) J. NAVARRO ALCACER & G. GAYOSO. *Revista de Ingenieria Industrial*, Vol. 2, Jan.-Feb. 1931, pages 7–10.

The Cr-V steel contained: C, 0.45–0.50%; V, 0.3–0.5%; Cr, 1–1.2%. It had an average hardness of 174 Brinell and 87.5 Rockwell. The critical point was found at 720° by a heating curve and 620° by a cooling curve. Hardening by heating to 850° and oil quenching produced a Brinell hardness of 470. With an increase in temperature to 1000°, the hardness increased to 482. WHB(10a)

The Deep Hardening of Structural Steels with Special Reference to the Influence of Cross-section of the Piece and Composition. (Die Durchvergütung von Konstruktionsstählen unter Berücksichtigung des Einflusses von Stückquerschnitt und Legierung.) H. KALLEN & H. SCHRADER. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, pages 387–388.

This abstract corresponds to the original paper in *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 383–392. See *Metals & Alloys*, Vol. 2, July 1931, page 132. GN(10a)

On Temper-Brittleness in Steel. S. MAITA. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 227–237.

In English. Includes discussion. A 0.54% C, a 0.30% C, 3.29% Ni, 0.59% Cr, and a 0.29% C, 2.93% Ni, 0.70% Cr, 0.86% Mo steel were compared by: (a) oil-quenching all from 850° C.; (b) quenching the carbon steel from 760° C. and the other two from 730° C., tempering all at 650° C. one hour and (a) furnace cooling, (b) oil quenching. On the carbon steel, slow cooling from the draw after high temperature quenching dropped the Izod from 20 ft.-lbs. to 14; after the low temperature draw it raised it from 20 to 25. On the Ni-Cr steel it dropped the Izod after high temperature quenching from 65 to 21; after low, from 71 to 66. On Ni-Cr-Mo it dropped it from 45 to 43 after the high temperature quench, and from 56 to 55 after the low temperature. Low temperature quenching is, therefore, advised. It was admitted that tensile and yield were not as good with the low temperature quench, but no figures were given. HWG(10a)

Heat Treated Rail Ends Resist Batter. M. D. BOWEN. *Metal Progress*, Vol. 19, Apr. 1931, pages 33–38.

The author describes end batter in rails and the former practice of welding onto the ends of the rails new material to take out the depression. This practice suggested that a hardening of the rail-ends by heat treatment might make the rail more resistant to end batter and eliminate some of the maintenance costs due to this cause. After some experimenting and with careful control, a technique has been developed for the heat treatment of rail ends rendering them almost immune to end batter. A special thermocouple device used to check the treating temperatures is described. WLC(10a)

Annealing (10b)

Annealing Cartridge Cases. B. W. BENEDICT. *U. G. I. Circle*, Vol. 11, Sept. 1930, pages 5–10.

The cartridge of the Springfield rifle, caliber 30, is made of brass of 70% Cu and 30% Sn. The process of manufacture and treatment is described in detail. It shows an unusual distribution of tensile strength: at the head 60,000 lb./in.², increasing to 70,000 lbs. at about ¾ in. further, then decreasing to about 40,000 lb. at the mouth. This is brought about by cold work and annealing operations. Ha(10b)

Case Hardening & Nitrogen Hardening (10c)

Behavior of Liquid Carburizing Baths. E. C. MOFFETT. *Iron Age*, Vol. 127, Apr. 23, 1931, pages 1338–1341.

Cyanide concentration of about 30% gives good penetration and hardness on low C steel. Use of temperature in excess of 1550° F. results in the deterioration of cyanide and does not increase the rate of penetration. NaCN and $Ca(CN)_2$ are used for liquid carburizing. Five general rules are given for using NaCN. Aerocase process consists of using molten salt bath Aerocase compound No. 510, to which is added small amounts of activating material. This is also known as $Ca(CN)_2$ method. Compares the 2 methods and gives results of investigations. VSP(10c)

An Appraisal of Nitriding. M. A. GROSSMANN (Republic Research Corp.). *Preprint* for May 1931 meeting, *American Iron & Steel Institute*, 10 pages; *American Metal Market*, Vol. 38, May 23, 1931, pages 3, 10; *Heat Treating & Forging*, Vol. 17, June 1931, pages 570–572, 575; *Iron Age*, Vol. 127, June 4, 1931, pages 1823–1826.

Review of progress since publication of Fry's A. S. S. T. paper in 1929. Eleven points then made by Fry are examined in the light of later knowledge. Newer practice may nitride first at 950°, and then at 1150–1200° F. to produce a thicker case. The case retains hardness at higher temperatures than it was previously supposed. For rust resistance, the outer skin of the case must not be removed. Free ferrite or surface oxidation must be avoided. Theories to account for the hardness of the case are still unsettled. It is suggested that Al, Cr, Mo and V, especially Al, form nitrogen compounds agglomerated to some degree and very finely dispersed in ferrite. The particle size is important and is dependent on nitriding temperature. If nitriding is started at too high a temperature, high hardness is not obtained. Nitriding pots deteriorate through some unknown mechanism in such manner that the efficiency of nitriding, on the work contained in them, decreases. An alloy of 25% Cr, 20% Ni, 55% Fe, or an enameled container, act the best. Nitriding steels can be welded by atomic hydrogen and the weld nitrided to 800 Brinell. Nitrided cases are not suitable for service in mineral acids, in clash gears or in sand-blasting nozzles. HWG+DTR(10c)

Hardening Steel Commercially by Cyaniding Process. E. F. DAVIS. *Steel*, Vol. 87, July 17, 1930, pages 43–46, 60; July 31, 1930, pages 47–48, 53; Aug. 14, 1930, pages 48, 50, 52.

Describes history of cyanide, properties and advantages of the various grades, and the mechanism of the hardening process. Discusses brittleness of cyanided work and its relation to the cyaniding temperature and quenching methods, cyaniding gears and wire, and advantages and disadvantages of the process. Treats of the relative merits of gas, oil and electric furnaces for cyaniding aerocase method, fume prevention, cyanide poisoning, and testing of the baths. Cyanide content of an operating bath should never be below 15% NaCN. Cyanided case usually contains 0.50–0.70% C, and 0.60–0.80% N, the latter being responsible for the hardness. Depth of penetration is governed by mass, time, temperature and percentage of cyanide in the bath. Brittleness frequently is caused by quenching the steel from cyanide at a temperature below the refining heat of the core. Majority of automobile gears are cyanided, this treatment being given to steels of SAE 2345, SAE 3250, SAE 6145 and SAE 5150 analyses. Three methods are used: (1) preheating to 1250° F. and finishing the heating cycle in cyanide; (2) cyanide dip or cyanide wash method whereby the steel is heated to the hardening temperature in a rotary or hump furnace and transferred to a molten cyanide bath held at some definite temperature from 1450° to 1500° F., and (3) direct process which consists in placing cold gears in the cyanide and bringing them up to heat in the molten bath. Steels which are austenitic, such as carburized 5% Ni and 3.5% Ni steels are not hardened as successfully in cyanide as the C-Cr and Cr-Ni steels. Gas furnaces are the best and most economical. Author has developed a continuous automatically-controlled, gas-fired cyaniding furnace. Rotation of a screw carries the work through the furnace Cast-steel pots are the best for gas- or oil-fired furnaces. Alloy pots are preferable for electric furnaces. MS(10c)

Mechanism of the Tempering of Martensite. P. CHEVENARD & A. PORTVEIN. *Comptes Rendus*, Vol. 191, Dec. 1, 1930, pages 1059–1062.

The phenomena of tempering are complicated by the simultaneous presence of austenite and martensite and the difficulty of obtaining the latter in a pure state. The proportion of austenite was estimated by the dilatometric method and conclusions were thus drawn as to the behavior of martensite itself. The following changes are taking place simultaneously: Martensite ⟶ cementite + martensite (with less C); Austenite ⟶ cementite + austenite (with less C); Austenite ⟶ cementite + martensite. Some of the physical changes are plotted against the tempering temperature, simultaneously with pure martensite and quenched steel. The hardness increases at first due to the fineness of the precipitated cementite particles and the increasing concentration of C in the α-phase, but on further increase of temperature it decreases rapidly due to the coalescence of the cementite particles. The hardness of the martensitic structure, therefore, passes through a maximum. As austenite is much softer than martensite, the curve of quenched steel is approximately parallel to the one of martensite in the beginning, but it approaches the latter with an increase of temperature due to the decomposition of austenite and merges with it when the change is completed. A similar conformity appears in the dilatometric curves, and should also exist for other physical and chemical qualities. The corrosion by acids, for instance, is a function of the content of C in the α-phase, which decreases with rising temperature, and also a function of the number of cementite particles which passes through a maximum. A maximum of coloration with etching reagents is predicted. (10c)

Carburizing Alloy Rivet Snaps. ARTHUR S. REARDON. *Metal Progress*, Vol. 19, June 1931, pages 49–53.

Breakage and design of rivet snaps are discussed. The erection of the Sydney Harbor Bridge was the occasion for difficulties described. A Cr-W steel, .38–.45% C, 1.10% Cr and 2.5% W was adopted at first. Softness and bad breakage traced to high Si content resulted in a search for a new steel. Case hardened $3^1/_2$% Ni steel was tried with excellent results. A Cr-Ni steel of .12–.18 C, 4.0–4.5% Ni and 1.0–1.4% Cr carburized for seven hours at 1690° F and cooled in the box, quenched from 1620° F., for the core, and 1400° F, for the case, in water was finally used. Case depth of $^3/_{32}$ in. was obtained. Three recuttings and recarburizings were possible with these snaps resulting in a life of 8000 rivets. WLC(10c)

The Progress in Nitriding of Steels. (Les progres de la nitruration des aciers.) LEON GUILLET. *Revue de Métallurgie*, Vol. 28, May 1931, pages 265–267.

The original 1.0% Al and 1.5% Cr steel was not improved until now. Small additions of other elements are helpful, but large ones interfere with the nitriding. Ni above 5% limits nitrogen absorption, and 20% prevents it entirely which makes high Ni steels suitable for nitriding chambers. Without Al no composition permits obtaining Vickers hardness of 1100–1200. Carbon is controlled by the desired properties of the core. Tinning is the simplest and best method for prevention of nitriding of desired areas. JDG(10c)

New Method of Speeding Nitriding. Correspondence from A. PORTEVIN, Paris, France. *Metal Progress*, Vol. 19, May 1931,, pages 86–87.

The writer recounts experiments in which steel attached to a rapidly vibrated plate became much more reactive to its surroundings. Nickel-chromium-molybdenum steel nitrided to a depth of .014 inches in less than 9 hours at 932° F. with a hardness of 1033 Vickers. Gray cast iron became decarburized to a depth of .003 inches and covered with a sooty deposit after 10 hours at 530°. Vibration obtained with a magnetic oscillator. WCL(10c)

On the Nitrification (Nitriding) of Pure Iron. T. TAZAWA. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 109–110.

In English. "Nitrogen penetrates into iron in sine periodic form, producing various iron nitrides which alternately form and decompose." HWG(10c)

Nitride Hardening of Alloy Steel for Diesel-Engine Use. C. R. ALDEN. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 2, 1930, *Oil and Gas Power*, pages 57–63.

Includes discussion. In this paper the author discusses metallurgical developments in the nitride hardening of alloy steels and the advantages that may be expected from increased use. With correct analysis of the steel, freedom from distortion in hardening depends upon the operations preceding nitriding. A sequence of operations is given, and nitriding equipment is described. Time necessary to produce and the cost of the nitrided product are given. (10c)

A Study of Carburization of Metals. A. A. RAVDEL. *Journal Russian Physico-Chemical Society*, Vol. 62, 1930, pages 516–522. (In Russian.)

A series of carefully made experiments was made by heating W and Mo filaments in vapors of naphthalene. Using 0.06 mm. $C_{10}H_8$ vapor pressure and heating W filaments several scores of times for different intervals it was found that their conductivity, measured at room temperature, reached a minimum and then rose to about 40% of the original conductivity, where it remained regardless of further heating. The amount of C absorbed was measured by determination of H pressure formed in the decomposition. The formation of W_2C was not complete, carbide and metal were always present together. Its production was possible on the reduction of $C_{10}H_8$ vapor pressure to 0.0015 mm. The speed of decomposition reaction and that of formation of carbides depends on the pressure and temperature, particularly when the penetration of C into the metal is slowed up by the presence of a superficial layer of carbides. In case of Mo the relation between conductivity and carbon content is different from W and is further complicated by the formation of several carbides only 2 of which, Mo_2C and MoC, were identified on the conductivity curve. (10c)

Present Status of Solid Carburizers. STANLEY P. ROCKWELL. *Iron Age*, Vol. 127, Mar. 26, 1931, pages 1009–1010, 1065.

A symposium conducted by the New York chapter of the American Society for Steel Treating. Early methods of applying bone and leather and gradual development of commercial carburizers are considered. Solid carburizing is a major heat treating operation. One advantage of solid over gas or liquid material is when Cu plated work is to be carburized. Evidence points to gaseous material as the future carburizer, but solid materials will still be used in large quantities. VSP(10c)

Cyanides in the Case-Hardening and Heat Treatment of Steel. W. NELSON. *Metallurgist*, Feb. 1931, pages 21–23.

The cyanides of sodium and potassium have been the subject of considerable investigation. Molten cyanides can now be worked economically in the region of 950° C. Modern research and practice have shown that cases up to 0.06 in. can readily be obtained in molten cyanides; that the possibility of exfoliation can be definitely eliminated; that the degree of hardness is no greater than that obtained by any other method of case-hardening and heat treatment, and can be reduced at will without tempering. Excellent results were obtained from a bath containing 20 lb. sodium cyanide and 20 lb. sodium carbonate. Melts containing either chlorides or potassium salts depreciated much more rapidly than baths which were free from these constituents. For example, a melt containing 8 lb. KCl, 12 lb. Na_2CO_3 and 20 lb. NaCN, was maintained at a concentration of 50% NaCN by additions of a mixture of 80% NaCN and 20% KCl. At a temperature of 950° C. this bath required $1^1/_2$ lb. of this mixture per hour as compared with the all-soda bath requirement of $^3/_4$ NaCN only per hour. The penetration obtained by the 50% Na_2CO_3 and 50% NaCN at a temperature of 950° C. was a case 0.06 in. deep in 6 hours' immersion, 0.03 in. in 2 hours and 0.005 in. in 5 minutes. Exfoliation was absent. Hardness, obtained from tests over a 2 years' period, was from 58 to 64 Rockwell and 70 to 80 Shore scleroscope. Salt baths are used extensively for heat treatment. Some of the melts used have the disadvantage of decarburizing the edges of delicate components, tools, jigs, etc. The presence of cyanide in the bath prevents this decarburization. Where the steel contains less than 0.9% C the cyanide content of the heat-treatment bath must be considerably reduced, as the carburizing effect of the full strength bath would result in an alternation in the composition of the steel. In preparing a heat-treatment bath containing cyanide, nitrates and nitrites cannot be used as diluents as the reaction between molten cyanide and salts containing oxygen is explosive. VVK(10c)

Quenching (10d)

Estimation of Internal Stresses in Quenched Hollow Cylinders of Carbon Tool Steel. O. V. GREENE (Carpenter Steel Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 369–403.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, September 1930. Includes discussion, 5 references to the literature and is illustrated by 10 drawings or photographs, 5 charts and 15 tables of stress and size changes. Two appendices are attached showing the method of estimation of the stresses. The internal stresses in hollow cylinders of carbon tool steel quenched by submerged flushing are tangential tension, or a combination of tangential tension and compression at the hole. The stresses at the holes of cylinders quenched by flushing at the holes are uniformly tangential compression and increase with the quenching temperature. The latter treatment is advantageous for pressure vessels. The axial stresses at the holes were compressional in all cylinders when present. The axial compression in the outside surface of quenched solid bars decreases with increase of hardness penetration, but increases with quenching temperature except in cases of complete hardening of the section. Layers under the martensite are considerably harder when cylinders are quenched from 1600° F. and those quenched from 1450° F. Cylinders quenched by flushing at the hole are uniformly in tangential compression at the hole after tempering at 450° F. The holes of cylinders quenched by submerged flushing at 1450° F. are in tangential tension at the center and compression at the ends, which condition remains after tempering at 450°, at 1600° F. submerged flushing results in uniform tangential tension, tempering leaves the centers in tension but the ends in tangential compression. Axial stresses increase with length of cylinders but never reach values that are of consequence. The advantages of quenching by flushing at the hole rather than submerged flushing are tabulated. WLC(10d)

Aging (10f)

The Influence on Ageing of Drawing After Quenching. W. FRAENKEL. *Metal Industry*, London, Vol. 37, Dec. 12, 1930, pages 559–560.

The influence of drawing after quenching on cold and hot aging, was studied on three types of ageable aluminum alloys: (1) a duralumin-type alloy, (2) a magnesium-free alloy containing copper and (3) an alloy containing zinc and lithium. Small drawing stresses (1 to 5%) and heavier stresses (20 to 60%) were applied, and the hardness and strength—in some cases, also the ultimate tensile strength and conductivity—of the metal were tested throughout the various stages of the treatment. The author was able again to confirm the long known fact that aging is hindered, or even stopped entirely, by drawing after quenching. Although aging phenomena are still clearly observable if the drawing stress is not too pronounced, much higher strength values are usually obtained if the material is finish-drawn after the aging process has been brought to an end. This sensitiveness toward drawing stresses is not uniform with the various alloys. It is most pronounced in the alloy containing zinc and lithium. The increase of electric resistance with progressive aging, which is quite apparent in the alloys of the duralumin type, is not as pronounced in pre-drawn material, thus proceeding parallel with the corresponding decrease in the amount of finish-drawing. After describing the experimental results obtained, the author offered some theoretical observations. (10f)

The Ageing of Permanent Magnet Steels. J. E. GOULD. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 273–292.

Aging of 36% Co, 5¾% Cr, 4% W, 0.9% C; 16% Co, 10% Cr, 1–⅔% Mo, 1.1% C; and 6% W, ½% Cr, ¾% C steels was studied, from 0° C. to 150–200° C. The 6% W steel lost its coercive force much more rapidly than the others at temperatures above 120° C. The curves for the 36% and the 16% Co steels are nearly parallel, the latter showing the lower percentage loss. The aging phenomenon is ascribed to a colloidal structure in the steel. HWG(10f)

On the Age-Hardening Mechanism in Al-Mg_2Si Alloys and in Duralumin. S. KOKUBO. *Kinzoku no Kenkyu*, June 1931, pages 289–310 (in Japanese); *Science Reports, Tohoku Imperial University*, Vol. 20, No. 2, pages 268–298 (in English).

Age-hardening mechanism in quenched Al-Mg_2Si alloys was investigated by measuring the changes in density, in electric resistance and in hardness caused by various modes of heat-treatment. The dilatation and thermal curves for the quenched specimens were also measured. The observed facts did not agree with the conclusions based on the precipitation theory of Merica and others as in the case of Al-Cu alloys, and the author has proposed a new theory, the solid solution theory, as in the case of Al-Cu alloys and it was found to fit very satisfactorily with the observed facts. According to the solid solution theory, the magnesium and silicon which are dissolved in dispersed state atomically in the space lattice of aluminum precipitate in three steps, that is, (a) magnesium and silicon atoms move within the lattice of aluminum and concentrate themselves to a configuration suitable for the formation of the compound; (b) a group of these atoms is precipitated as the compound; (c) then these molecules or molecular groups coagulate themselves and build up a space-lattice characteristic of the compound. These processes may take place in close succession or partially overlapped. By the process (a) above mentioned, the distorsion of aluminum lattice is greatly increased in age-hardening at room temperature to 150° C. This causes the increase in electric resistance, a decrease in density and an absorption of heat; and these facts are the objections to the precipitation theory. In tempering at 150° to 250° C., the two processes (a) and (b) take place briskly and hence the density greatly increases, the electric resistance diminishes markedly and a great heat evolution takes place. The tempering in the range 250° to 450° C. causes process (c) to take place. The recrystallization of the matrix will also take place, by which the surface and strain energies are transformed into heat and hence a heat evolution is observed. The mechanism of age-hardening in duralumin was clearly explained as the combined effects of the age-hardening of Cu-Al alloy and of Al-Mg_2Si alloy. KT(10f)

Malleableizing (10g)

Malleable Castings, from the Practice—for the Practice. (Der Temperguss; aus der Praxis—für die Praxis.) PAUL VIDOR. *Giesserei-Zeitung und Giesserei*, Vol. 18, Jan. 2, 1931, pages 8–14.

Possible applications for malleable iron, its composition, the importance of C, Si, Mn, P, S and their mutual action are discussed in detail. The actual process during malleableizing isexplained. The equipment for a foundry, molding and molds, melting and pouring is described and illustrated. The calculation of the composition of the raw material for a given end product is discussed and explained by curves. Ha(10g)

High Quality Malleable Casting. (Ueber hochwertigen Temperguss.) E. PIWOWARSKY. *Giesserei-Zeitung und Giesserei*, Vol. 18, Jan. 2, 1931, pages 19–24.

The quality of modern malleable iron has been considerably improved by competition with steel castings. Its properties are between those of cast iron and steel, but it has been more expensive than steel. The conditions for producing black iron may be simpler than those necessary for white iron. It shrinks less and has a higher elongation than white iron and is, therefore, more economical. The methods of production, the influence of wall thickness and content of Mn and the possibilities of refining are explained and treated in detail and illustrated by Diagrams. Micrographs show the influence of different annealing temperatures on carbonization. The addition of Ni and Cr greatly improves the mechanical properties. For details, the reader must refer to the paper and to the 26 references which supplement the article. (10g)

Malleable Iron by Short Anneal. C. B. PHILLIPS (Surface Combustion Co.). *Metal Progress*, Vol. 19, Mar. 1931, pages 99–102.

Practice developed at Southern Malleable Iron Co., East St. Louis, Illinois in reducing the time of annealing for malleableizing is described and discussed. WLC(10g)

The Theory of Malleableizing of Cast Iron according to American Methods. (Die Theorie des Temperns von Gusseisen nach amerikansichen Verfahren.) N. HEKKER. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Jan. 2, 1931, pages 14–19; Jan. 9, 1931, pages 39–45.

When cast iron is malleableized in an annealing process, the disintegration of iron carbide Fe_3C in $3Fe + C$ is initiated. The material is kept at this temperature and then slowly cooled so that this reaction can be fully completed. The manner of calculation of the amount of solid solution and several analyses are cited. The most favorable conditions for tempering are described; failures are investigated and their causes are explained. Examples of calculation of a material of definite qualities illustrate the conclusions. Ha(10g)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

The Viewpoints for the Training of Welding Personnel with Particular Reference to the Welding Engineer. (Die Gesichtspunkte für die Ausbildung des Schweisspersonals unter besonderer Berücksichtigung des Schweissingenieurs.) W. PROX. *Autogene Metallbearbeitung*, Vol. 23, Sept. 15, 1930, pages 283–286.

A paper discussing the education of welders from the standpoint of the designing, operating and erecting engineer, theoretical as well as practical. Ha(11c)

Some Problems of Resistance Welding. C. L. PFEIFFER. *Journal American Welding Society*, Vol. 10, Apr. 1931, pages 5–11; *Welding*, Vol. 2, June 1931, pages 377–383.

Some fundamental concepts of resistance welding are discussed for the purpose of determining their applicability to specific problems in the design and manufacture of apparatus assemblies and machinery. The factors to be considered in resistance welding are current density per unit area, time of current cycle, pressure per unit area, electrical conductivity of the parts being welded, heat conductivity of the parts, specific heat of the parts, melting points of the materials, medium in which the joint is to be made, cooling stresses, heat fusion, contact resistance. The proper design of welded apparatus assemblies should take into account the type of joint, choice of material, shape at the point of welding and accessibility of electrodes. The materials most universally used for welding are, in order of their weldability, wrought iron, low carbon steels, nickel, nickel silvers, monel bronze, galvanized iron, permalloy, high carbon, silicon, cobalt or chromium steels, duralumin, nichrome or chromel, aluminum, copper, brass, zinc, lead. The advantage of automatic welding is discussed and a few special cases, such as welding of small pieces of rare metals to other materials, are treated more fully. Ha(11c)

Development and Present State of Rail Welding. (Entwicklung und gegenwärtiger Stand der Schienenschweissung.) M. REITER. *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 85, Sept. 15, 1930, pages 398–405; Oct. 1, 1930, pages 419–432.

The author gives an exhaustive outline of the development and present state of rail welding and arrives at the conclusion that a completely satisfactory solution of the problem is not attained as yet by any of the various welding methods. The subsequent heat-treatment results in an improvement of the grain size, but not in an essential gain in physical properties. A large part of the paper is devoted to the utilization of the following testing methods for the investigation of the seam: tensile strength, cold bending test, impact bending test, impact test with notched samples, impact endurance tests and Brinell hardness test. The paper includes 46 illustrations which refer to welding equipment, various welding methods, microstructure of welded seams, macro-photographs etc. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 82. EF(11c)

Manufacture of Welding Wire. GEORGE S. ROSE. *Iron & Steel Engineer*, Vol. 8, May 1931, pages 227–229.

Paper read before the Pittsburgh Section Jan. 21, 1931. The author discusses the manufacture of welding rod, the care necessary and the testing required to produce the best product. Tests for the users are urged in order to obtain proper selection for the job. WLC(11c)

Ramblings in the Field of Welding Technique. (Schweisstechnische Streifzüge.) HANS A. HORN. *Die Schmelzschweissung*, Vol. 9, Apr. 1931, pages 75–78; June 1931, pages 135–137.

This is a report of experience in the welding of new metals and alloys gained in the experimental and training shops for welding technique in Berlin. The tests made on them are outlined. Reports are made on welding and soldering of aluminum alloys (pipes, tanks, safety belts), fluxes, light metals and refining. A tabulation of physical and mechanical properties of normal and refined aluminum alloys, manganese alloys and cast alloys is added. The tests have shown, throughout, that a heat treatment of welds of refined aluminum alloys is inadvisable because invariably the weld and the neighboring annealed places show not more than 65% (usually less) of the normal tensile strength; the elongation is still less. Castings, however, showed a better result than the original material. Another chapter discusses the properties of beryllium to increase the strength of Cu and Al-bronzes and the extraordinary increase of electrical conductivity of more than 100%. A good flux for the welding of electron metal is given as:

potassium chloride	45%
sodium chloride	30%
lithium chloride	15%
potassium bisulphate	3%
potassium fluoride	7%

The question of soldering and welding of electron castings is also discussed. A really reliable, permanently stable method has not yet been found. Ha(11c)

The Behavior of High-Carbon and Alloyed Electrodes for Wear-Proof Built-Up Welds in Welding with the Electric Arc. (Das Verhalten kohlenstoffreicher bezw. legierter Elektroden für verschleissfeste Auftragsschweissungen bein Verschweissen mit dem elektrischen Lichtbogen.) KARL TEWES. Doctor's Thesis. *Die Schmelzschweissung*, Vol. 9, Apr. 1931, pages 79–82; June 1931, pages 138–142.

This very comprehensive investigation of the chemical-physical properties of electrodes extends to the following subjects: (1) the melting times were determined for different polarities; (2) under the same conditions, the quality of molten metal (in g./sec.) was also determined; (3) the burnt-away part of the electrodes, that is the difference in percent of the component parts of the alloy before and after welding, has been determined at different polarity by chemical analysis; (4) the burning depths, that is, the degree of melting-together of electrode material with the parent material, was determined; (5) the hardness of the beads was determined for different polarities and currents. The arrangement and equipment of tests and analysis of materials is described. The test results are reproduced by curves, tables and micrographs. It can be concluded that the resistance to wear is determined not only for the hardness, tensile strength and toughness of a material but can be influenced also by some unknown interior properties, such as change of interior resistance due to change of structure. Ha(11c)

Removing Rivets with Arc on the C. & O. C. W. BEBOUT. *Welding*, Vol. 1, Nov. 1930, pages 895–896.

Twenty-five steel cars can be dismantled in a day in the car shops by using the carbon arc cutting process. One operator burns form 800 to 1200 rivets per 8 hr. day. Shop facilities, equipment and procedure are described. The average cost of removing 1000 rivets by this process amounted to $11.54. Ha(11c)

Cost of Structural Steel Welding. G. D. FISH. *Welding*, Vol. 1, Dec. 1930, pages 986–989.

Explains the manner of making up cost sheets, covering cost of steel, shop fabrication, shop and field welding, erection, painting, drawings and inspection. A few sample cost sheets are made up. Ha(11c)

High and Low Pressure Welded Pipe Lines. E. R. BENEDICT. *Welding*, Vol. 1, Nov. 1930, pages 913–914.

Description of a tunnel designed for the use of welded structural steels and a large completely welded steam separator. Ha(11c)

A Simple Practicing and Testing Device for Gas Welders. (Eine einfache Uebungs- und Prüfvorrichtung für Gasschmelzschweisser.) WILH. GELDBACH. *Die Schmelzschweissung*, Vol. 9, Sept. 1930, page 216.
Describes a device for a beginner to practice using in holding burner, electrode, adjusting flame, etc., in order to save material. Ha(11c)

German Engineers Study Welded Joints. Correspondence from E. W. EHN, Cannstatt, Germany. *Metal Progress*, Vol. 19, Mar. 1931, pages 90–91.

Welding of Stainless Steel. J. W. HOSTETTLER. *Journal American Welding Society*, Vol. 9, Dec. 1930, pages 48–60.
Includes discussion. See "Welding of Rustless Steels is Making Progress," *Metals & Alloys*, Vol. 2, April 1931, page 83. (11c)

Repair Work on the Tray of a 15,000 m³ Filled Gas Storage Tank by Electric Welding. (Reparateur der Tasse eines gasgefüllten Gasbehälters von 15,000 m³ Inhalts mittels elektrischer Schweissung.) D. T. METZDORF. *Das Gas- und Wasserfach*, Vol. 74, Jan. 1, 1931, pages 9–12.
The cheap method of repair by electrical welding is discussed, schematically illustrated and the various stages during the repair work shown in 13 illustrations. EF(11c)

Experiments with Cast Iron Cold Welding. (Untersuchungen über Gusseisen-Kaltschweissung.) H. BUCHHOLZ. *Die Schmelzschweissung*, Vol. 9, Aug. 1930, pages 183–187.
In order to check certain results, published in the literature, obtained with specially covered electrodes, a series of tests was made. When cold welding cast iron, the formation of cracks, nitrides and gas bubbles and the bindability have especially to be watched. They are discussed and the importance of Al, Mg and Si as additions to the coating of the electrodes is pointed out. The results obtained differed greatly from previously published results. In order to explain the differences, the temperature range of the iron, within which it is possible for an absorption of C to take place, was determined. As maximum, a content of 2.7% C could be obtained in the seam. The character of the seams for the different electrodes used is shown in microphotographs. Ha(11c)

Instruction and Training in Welding Technique. (Der Unterricht und die Ausbildung in der Schweisstechnik.) E. KALISCH. *Die Schmelzschweissung*, Vol. 9, July 1930, pages 166–167.
Discusses a series of welds a student should do and some books for his use which have proved useful. Ha(11c)

Welding Applied to Maintenance Work. E. H. PACY. *Welding*, Vol. 1, Jan. 1930, pages 171–173.
Describes a few examples of structures having been strengthened by welding and tests made during progress of the work. Ha(11c)

Additional Welding-On of Rolled-On Flanges. (Zusätzliches Verschweissen von aufgewalzten Flanschen.) H. HOLLER. *Autogene Metallbearbeitung*, Vol. 23, Apr. 1, 1930, pages 99–104.
Tests have shown that additional welding of flanges which are rolled or screwed on can be successfully applied to strengthen and tighten the joint. Ha(11c)

Description of building and equipment donated by the city of Berlin, as well as curriculum, lectures, etc. Ha(11c)

Experiences with Acetylene-Welded Rims of Supporting Rolls. (Erfahrungen mit azetylengeschweissten Stützrollenbandagen.) H. HOLLER. *Autogene Metallbearbeitung*, Vol. 23, May 1, 1930, pages 137–139.
A few suggestions on the welding of rims of rolls which are under heavy pressure supporting rotating drums, tanks and containers in mills, crushers, etc. Ha(11c)

The Behavior of High Carbon Addition Materials for Built-Up Welding in the Electric Arc. (Das Verhalten kohlenstoffreicher Zusatzwerkstoffe für Auftragsschweissungen im Lichtbogen.) W. HOFFMANN. *Die Schmelzschweissung*, Vol. 9, Oct. 1930, pages 229–230.
The determination of melting time with different polarity is of importance only for additions with low carbon contents. Materials with more than 0.25 C can be welded only on the positive pole. The test results show that these materials have a higher seam strength than the strength of the material. On an average, it was increased from 45 kg./mm.² to 65 and 81, respectively, for 2 different materials. It was further found that, with increased current, the strength is reduced. Ha(11c)

The Welding Training Shop of the State Vocational School at Siegen. (Die Schweisslehrswerkstatt der Staatlichen Fachschule Siegen.) DIR. HENSCHER. *Autogene Metallbearbeitung*, Vol. 23, May 1, 1930, pages 139–141.
Opened 1929; 17 welding places. Description of building and equipment. Ha(11c)

The Training of the Fusion Welder. (Ueber die Ausbildung des Schmelzschweissers.) OTTO MIES. *Die Schmelzschweissung*, Vol. 9, Aug. 1930, pages 175–177; Sept. 1930, pages 202–205.
Paper read before the convention of the Association for Autogenous Welding in Halle, June 1930. The principal points covered are: the training of welding experts, including welders, foremen and engineers, can be done thoroughly only by practical experience; a welder must serve an apprenticeship; the different grades of schooling and training have been arranged in the courses of the Verband für Autogene Metallbearbeitung. At present, the most acute question is the education of engineers, both operating and designing, for whom, as yet, no definite curriculum has been formulated. Ha(11c)

The New Welding Training Shops of the State United Technical Schools in Dortmund. (Die neuen Schweisslehrwerkstätten der staatlichen vereinigten Maschinenbauschulen in Dortmund.) MUELLER. *Die Schmelzschweissung*, Vol. 9, Oct. 1930, pages 223–224.
Description of buildings and equipment. Ha(11c)

Shrinking Stresses in Welding. (Ueber Schrumpfspannungen beim Schweissen.) H. W. NIES. *Die Schmelzschweissung*, Vol. 4, Apr. 1930, pages 85–87.
Takes issue with the paper of Mies, Nov. 1929, about certain assumptions to explain the cause of shrinking stresses. The actual occurring of fractures of welded seams point to exactly the opposite of the conclusions arrived at by Mies, namely that the greatest danger of breaking exists when welding small strips together and that with wider strips this danger decreases; the very opposite is the case. The author develops, therefore, formulas which cover actual conditions much better; this is largely due to the fact that the expansion by heating of the parts to be welded is taken into account which, in the other paper, had been neglected. Ha(11c)

The New Regulations for Rating and Testing of Direct-Current Arc-Welding Machines RESM/1931. (Die neuen Regeln für die Bewertung und Prüfung von Gleichstrom-Lichtbogen-Schweissmachinen RESM/1931.) LOTTMANN. *Die Schmelzschweissung*, Vol. 9, June 1930, pages 132–134.
The new German regulations proposed by the VDI are reprinted in full with comments and explanations. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 10. Ha(11c)

Gas-Welding Machines in Germany. K. P. BERTHOLD. *Welding*, Vol. 1, Oct. 1930, pages 815–819.
A comparison of the uses of gas welding in the United States and in Germany. In Germany, longitudinal seams subjected to heavy stresses are preferably gas-welded because this method gives a stronger seam than an electrically welded seam. The construction of some automatic welding machines, both for longitudinal and for circular seams, is described. Ha(11c)

Automatic Shape-Cutting for Machine Parts. R. W. BOGGS (Linde Air Products Co.). *Iron Age*, Vol. 126, Aug. 14, 1930, pages 416–417.
Increased use of oxy-acetylene shape-cutting is due to recent perfection in the machine which increases accuracy in cutting. When many identical pieces are to be cut, templets are used to direct the cutting flame. Cuts are so smooth and accurate that for many purposes further machining is unnecessary. Most important uses of automatic shape-cutting machines are for fabricating machine bases and frames. If steel having a C content higher than 0.25%, or a definite content of alloy, is to be cut it should be preheated before cutting and afterwards normalized. VSP(11c)

Uses of Steel Castings as Affected by Welding. R. A. BULL (Director Electric Founders' Research Group). *Metal Progress*, Vol. 19, Feb. 1931, pages 70–76, 154.
The author states erroneous impressions are abroad regarding the extent to which steel castings are being replaced by welded structures or have been replaced by forgings in high pressure pipe lines. Quality of steel castings, their applications, and joining of small castings of good quality by welding are discussed. WLC(11c)

Designing for Rapid Production of Spiral Welded Pipe. LEON CAMMEN. *Machine Design*, Vol. 3, April 1931, pages 45–47.
Description of a machine which does the following: prepares the skelp, coiling it into desired shape, joins the seam, welds the seam, and cuts off the pipe. The single steps are discussed at length. Ha(11c)

Fabrication by Arc Welding. A. M. CANDY (Westinghouse Electric & Mfg. Co.). *Electric Journal*, Vol. 28, June 1931, pages 345–349.
An abstract of a paper read before the American Society for Testing Materials, Mar. 18, 1931. To obtain the maximum benefit from arc welding, the structure must be designed specifically for this process. Several examples are discussed to show the open-minded approach to this process by construction men. Twelve advantages of arc welding in fabrication are listed. WHB(11c)

A Neutralized Welding Generator. F. CREEDY. *Electrical Engineering*, Vol. 50, June 1931, pages 412–414.
By reducing the magnetic energy stored in the generator field, transient currents in d. c. welding machines can be largely eliminated. Providing such generators with neutralizing windings reduces this energy to a minimum. The stability of all welding apparatus is defined in terms of what may be called the "stability ratio" and this is defined and measured by: (1) applying full load to the welder by means of a resistance; (2) by arranging a switch so that the resistance may be short circuited instantly, short-circuiting the terminals of the machine through the steadying reactance, and (3) by measuring the maximum current kick produced when the short-circuiting switch is closed. The stability ratio is the ratio of this maximum kick to the normal full-load current. Results of a thoroughly mathematical study of problems involved are briefly summarized. WHB(11c)

The Examination of Welders by Means of Tests of Sample Welds. (Die Prüfung der Schweisser an Hand der Untersuchungen von Probeschweissungen.) ECKERMAN. *Die Schmelzschweissung*, Vol. 9, July 1930, pages 151–157.
The qualification of an electric welder can, in the opinion of the author, be judged properly only by thorough tests of the welds he makes. He has developed a welding examination where the welder has to weld boiler plates of 12 mm. thickness in different positions with a given electrode. The welds are tested for bending angle, tensile strength, elongation. Details of methods of welding and test forms are described. Ha(11c)

Electric Stitching or Lap Spot-Welding. (Die elektrische Stepp- oder Laschen-Punktschweissung.) A. DAMBEK. *Die Schmelzschweissung*, Vol. 9, July 1930, pages 168–169.
Simple electrical spot welding has the disadvantage of requiring overlapping if the joint is to have sufficient strength. A new method is described: the "stitch spot-weld." The parts to be joined are, as in butt welding, laid against each other without space between and a flap over them on the underside. Then spots of metal are melted on, overlapping each other so that the seam has the appearance of a stitched piece. A machine for this kind of welding for almost any type or size of work piece is described. The upper electrode is moved up and down about 250 times/min.; the diameter of the spot is about 3 to 4 mm. for a sheet of 1 mm. and a flap of 0.5 mm. The overlapping of the points is about 0.6 to 1 mm. Ha(11c)

Electrical Arc Welding as Capillary Phenomenon. (Die elektrische Lichtbogenschweissung als Kapillarvorgang.) P. FLAMM. *Die Schmelzschweissung*, Vol. 9, May 1930, pages 105–110; July 1930, pages 162–165.
Experiments with slow-motion moving pictures have corroborated the view, expressed earlier by this author, that in arc welding the electrode melts in drops. Each drop grows in the electric arc to a size which is given by the physical laws of capillary action. If this size is exceeded, the weight of the drop is sufficient to separate the drop from the end of the electrode by gravity and, immediately, a new drop is being formed. The velocity of forming drops is mainly dependent on the current density; with increasing density, the number of drops increases. The conditions are fully discussed with reference (1) to the support the drops find on the electrode and to the shape of the drops from the time of their inception until their junction with the work material, that is, while forming a bridge from the electrode to the work piece; (2) how the capillary tension determines the size of drops and the welds. Analogous conditions can be created by dipping an iron rod into oil and slowly extracting the rod, a bridge similar to the iron drop is then formed by the oil drop between rod and oil surface. This method has been used for measuring exactly size and diameter of bridge. The films then showed the different shapes of the bridge. Ha(11c)

The Development of the German Large Butt-Welding Machine. (Der Werdegang der deutschen Gross-Stumpfschmelzmaschine.) A. DAMBEK. *Die Schmelzschweissung*, Vol. 9, Sept. 1930, pages 210–213.
This machine was developed especially for butt welding or melting together very thin sections such as those of 1000 mm. length by 0.8 to 1.0 mm. thickness, as in the case of the manufacture of automobile bodies. The principal characteristics of this machine are (1) relatively low energy consumption because the actual welding time is very short (1000 × 1 mm. about 5 to 7 sec.); (2) very small heating zone, therefore no warping; (3) if properly welded, sufficient strength (97 to 100%) and perfect tightness; (4) very small change of grain in the weld; (5) very little machining after welding to obtain good appearance. The latest type can make 40 to 60 welds in one hr. of maximum 1300 mm. length by 1 mm. thickness; for smaller objects, 80 to 120 butt welds can be made. The mechanical construction with the electrical part is fully described. Ha(11c)

Welded Pipe Joints in Steel Architecture. (Geschweisste Rohrverbindungen im Stahlhochbau.) R. ULBRICHT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, June 13, 1931, pages 759–760.
A few illustrations of correct and incorrect joints of pipe construction with and without gusset plates at the joints. Ha(11c)

Welding of Corrosion Resisting Steels. Part II. WM. SPRARAGEN. *Welding*, Vol. 1, Dec. 1930, pages 979–980.
General instructions are given for the technique used in welding these steels by the various processes. They can all be satisfactorily welded although in some subsequent annealing is necessary. Ha(11c)

Analysis of Steel for Welding. W. E. STINE. *Metal Progress*, Vol. 20, Aug. 1931, pages 91–94.
Effects of aluminum as alloy and oxide, of manganese and silicon on the character of weld produced are discussed. Use of a fully shielded arc and an "autogenizer" are described and discussed. WLC(11c)

Pipe Welding, How, When and Where to Do It. WM. SPRARAGEN. *Welding*, Vol. 2, July 1931, pages 450–454.
The third installment deals with refrigerating piping, welded building and residence piping, thermit and resistance welding of pipe, welding of cast iron pipe, automatic carbon arc-welding. The respective procedures are briefly described. Ha(11c)

Commercial Production of Welded Steel Machinery Parts. G. D. SPACKMAN. *Iron Age*, Vol. 126, July 31, 1930, pages 290–291, 314.
Capital outlay for welded steel fabrication is large and manufacturer is justified in gaining experience before making heavy expenditures for equipment and alterations. Production of welded structures involves 3 important requirements: (1) use of welding quality steel; (2) weld metal having physical properties at least as good as original unwelded steel; and (3) rigid procedure control of welding operations. Material handling is of importance so far as production rate is concerned. There are wide applications for utilizing plate steel but welded steel construction cannot replace all castings. VSP(11c)

Possibilities of Repairing Aluminum Pieces by Soldering and Welding. (Ausbesserungsmöglichkeiten von Aluminiumwerkstücken durch Löten und Schweissen.) H. REININGER. *Die Schmelzschweissung*, Vol. 10, May 1931, pages 117–120.
Continued from the April issue. In this installment, the kinds of parts and defects which can be mended by soldering or welding and the production and properties of the soldered and welded joints are discussed and illustrated by means of photographs and sketches. Ha(11c)

Hydraulic Turbine Repaired by Electric Welding. C. R. REID. *Power*, Vol. 73, Mar. 24, 1931, pages 478–479.
A vertical-shaft Francis-type cast-iron runner 12 ft. in diameter and weighing 70,000 lbs. failed. The unit was rated at 20,000 h.p. at 120 r.p.m. under an 80 ft. head. Apparently one of the runner buckets had been cracked through at the upper end near the hub for some time. Other runner buckets were cracked. The broken ones were replaced with cast steel and the cracked ones repaired, all by electric welding. The unit is operating satisfactorily. VVK(11c)

Shield Welded Pressure Vessels Now Safe for All Hazardous Uses. G. RAYMOND. *Petroleum Engineering*, Vol. 2, Midyear, 1931, pages 147–148, 150.
Discussion of the shielded welding process which forms joints of nearly 100% efficiency between parts of almost any thickness or shape. (11c)

Welding of an Aluminum Crankshaft Case of a Bus. (Schweissung eines Aluminium-Gehäuses eines Omnibusses.) W. K. RAABE. *Die Schmelzschweissung*, Vol. 10, May 1931, page 126.
Describes the repairing of a crack of 25 cm. length due to the continuous vibrations. The case was preheated to 100° C. Ha(11c)

The Design of Welded Steel Structures. Part VI. H. A. MCCREADIE. *The Welder*, Vol. 2, Apr. 1931, pages 2–4.
This installment deals with the general construction of plate girders. The distribution of stresses is discussed in general. Ha(11c)

Shrinking Stresses in Welded Seams. (Schrumpfspannungen in Schweissnähten.) K. MELCHER. *Die Schmelzschweissung*, Vol. 10, May 1931, pages 128–129.
Shrinking stresses are produced in the following manner: After welding, the melt entirely fills the space between the parts to be joined. Solidifying, the weld shrinks and tries to approach the two parts. If these are kept rigidly in place, the melt must keep the same width in spite of its tendency to shrink and tensile stresses are the result. Such shrinking stresses are greater in butt-welded seams than in fillets. Several cases of shrinking conditions are discussed. The influence of size, weight and manner of support of the piece to be welded are explained. A basis is given on which to decide whether the pieces must be clamped rigidly or remain freely movable to avoid stresses in the finished state. Ha(11c)

Welding with Atomic Hydrogen Process. Part II. SAM MARTIN. *Welding*, Vol. 1, Dec. 1930, pages 990–991.
A brief description with illustrations of the proper methods of welding steel castings, alloy steels and other metals and the repair of dies. The consumption of hydrogen depends on the size of the equipment and the current used; it varies between 35 and 50 ft.^{3}/hr. at a pressure of from 1 to 2 lb./in.^{2}. Care must be taken that no leaks occur because a mixture of air and hydrogen is highly explosive at from 9.5 to 74% hydrogen by volume. Directions for the storing of hydrogen are given. Ha(11c)

Progress in Arc Welded Construction of Oil Pipe Lines. J. F. LINCOLN. *Oil Weekly*, Vol. 61, May 8, 1931, pages 67–68, 76.
Advantages of this method are increased ductility and resistance to corrosion in the welded joints, greater construction speed, reduced maintenance and repairs, increased life and more economy. (11c)

Welding Essential in the Coal Industry. C. B. LEBON. *Welding*, Vol. 1, Dec. 1930, pages 971–974.
The Pittsburgh Coal Co. saves much time and money in repairs of the mining equipment of their 19 mines by welding. Ha(11c)

The Progress of Arc Welding. German and American Practice in the Shipyards. E. D. LACY. *Metallurgia*, Vol. 4, July 1931, pages 89–90.
Welding in ship construction has proved very satisfactory both in Germany and in the U. S. Welded seams do not corrode any faster than other parts of the plates. Welding allows the weight to be decreased. Welded German vessels can carry larger guns than riveted vessels because the firing of the guns would shear the rivets, while it does not damage the welded construction. JLG(11c)

Testing of Welding Burners for Low-Pressure Acetylene. (Das Prüfen von Schweissbrennern für Niederdruckazetylen.) W. KNOCH. *Autogene Metallbearbeitung*, Vol. 24, June 15, 1931, pages 179–183.
The requirements of a welding burner are discussed with regard to economy and safety; especially the safety against backfiring must be absolute. Several constructions are described and tests on 4 burners are reproduced. Ha(11c)

Sil-Fos
BRAZING ALLOY
(patent applied for)

A DISCOVERY important to brazers of non-ferrous metals.

MELTS AT 1300° F.—

—compared with 1600 to 2100° for most brazing alloys. The melting point of SIL-FOS is even lower than silver solders containing less than 50% silver, which require 1400 to 1600°.

REQUIRES LESS FLUX—

—as the phosphorus in SIL-FOS has a fluxing action. In some cases, *copper-to-copper* joints can be made without any flux. This characteristic insures better results in the hands of the average workman and reduces the time required for cleaning and finishing.

MAKES STRONG, SOUND JOINTS—

—quickly. SIL-FOS is free flowing. It penetrates deeply and alloys with adjoining metal, making a strong, sound bond.

WORKS ON MANY METALS—

—copper, brass, bronze, extruded brass and bronze, monel metal, nickel and other non-ferrous metals and alloys.

SOLD BY THE POUND—

—in rod, thin strip and pulverized forms, at remarkably low prices for a silver-alloy.

Send for Bulletin No. 511MA for more complete information.

New York, N. Y.

Bronze Welding of Steel and Cast Iron. THOS. D. KETCHBAW. *Welding*, Vol. 1, Dec. 1930, pages 981–985.

In this practice, no fusion between weld and parent metal takes place but it is an adhesion somewhat resembling soldering in principle. The surface pores of the metal become enlarged by the increased temperature and allow the molten bronze to be drawn into the pores by capillary action. When cold again, the contracted parent metal holds the bronze. A detailed description of the preparation of the pieces to be welded and the procedure refers especially to locomotive frames and cylinders. Illustrations of the welded pieces are included. Ha(11c)

Cost of Using Welding. ROBERT E. KINKEAD. *Metal Stampings*, Vol. 4, Jan. 1931, page 28.

Paper presented at the fall meeting of the American Welding Society. See *Metals & Alloys*, Vol. 2, Jan. 1931. JN(11c)

The Spot Welding of Stainless Steel. JOHN F. HARDECKER. *Airway Age*, Vol. 13, July 1931, pages 36–39.

Describes the general trend of spot welding in aeronautical design, particularly with the "18 and 8" chromium and nickel stainless steel. Experiments carried out at the Edward G. Budd Company, Philadelphia, indicate encouraging results of spot welded members. A wing rib loaded to half of its ultimate factor, and this load released and reapplied 80 times a minute, at the same time a vibration of 1800 periods a minute is produced to simulate a rough engine, showed, after 1,400,000 cycles, no signs of weld or material failure. Much remains to be done, but spot welded stainless steel construction has had a truer introduction to aeronautical utilization than has any other new material. It appears to be one of the few instances where a new material has been investigated scientifically where no immediate interest in the marketing of the material is involved. WAT(11c)

Training Arc Welding Operators. A. F. DAVIS. *Electrical Manufacturing*, Vol. 8, July 1931, pages 29–30.

A student welding operator should be instructed primarily in the control of the welding current and be given the opportunity to spend much time in practice. He should be taught that arcs are injurious to the skin and eyes and require constant protection for these parts. He should first master welds on flat pieces, then advance to vertical welding. WAT(11c)

Electrical Resistance Welding. M. L. ECKMAN. *Western Machinery World*, Vol. 22, Aug. 1931, pages 357–361.

Each type of welding is described in detail. Mechanically operated flash welding, butt welding, spot and projected welding, seam welding and resistance welding are described. A table is given presenting spot welding data showing K. W. and H. P. required to weld sheet material from .0125 to .25 inches in thickness. WAT(11c)

Copper Alloy Welding Rods. I. T. HOOK. *Iron & Steel Engineer*, Vol. 8, July 1931, pages 337–341.

List of nineteen welding rod materials shows their melting points, thermal conductivity, coefficient of linear expansion and average strength of welds. Objectionable materials are briefly discussed. Seventeen welding properties are enumerated and discussed in connection with the materials listed. Applications are briefly discussed. WLC(11c)

Welding. C. A. ADAMS and others. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Published 1931, Vol. 36, *Mining and Metallurgy*, Part 4, pages 247–332. 95 figures.

A brief résumé comprising short comments as follows: Foreword, C. A. Adams; Procedure Control in Welding, H. H. Moss; Welding Wire, C. A. McCune; Welding Apparatus, E. H. Ewertz; Structural Steel Welding, F. P. McKibben; Arc Welding as a Factor in Construction Economy, G. D. Fish; Replacement of Castings by Welded Steel, J. F. Lincoln; Developments in the Welding of Pressure Vessels, C. W. Obert; Welding of All-Steel Automobile Bodies, J. W. Meadowcroft; Welding as Applied in Automotive Production Methods, by M. L. Eckman; Welded Steel Pipe, A. Hazen; Making High Pressure Pipe by Arc Welding, T. M. Jasper; Welding in Track Construction and Maintenance, E. M. T. Ryder; Welding in the Overhead Line Department, W. J. Quinn; Welding in Car Maintenance, J. S. McWhirter; Welding on Railroad Equipment, G. H. Giertsen; Shipbuilding, J. W. Owens. There are only 40 pages of text for these 17 articles, and 44 pages of illustrations. HWG(11c)

Arc Welding in Machinery Manufacturing. A. F. DAVIS. *Tech. Engineering News*, Vol. 12, 1931, pages 115, 147.

A late development in arc welding has been the introduction of the shielded arc. This new process produces welds on mild rolled steel with a tensile strength of 60,000 to 75,000 lbs./in.^{2} that are extremely ductile and highly resistant to corrosion. The principle of the shielded arc consists in preventing the oxygen and nitrogen in the ambient atmosphere from combining with the weld metal while in the molten state. Molten weld metal has a great affinity for oxygen and nitrogen, and when welding is carried out under conditions where these gases are readily available, oxidation and nitrification proceed at a high rate. These oxides in the weld impair its strength, ductility and resistance to corrosion. If the molten weld metal is protected from the atmosphere during the process of deposition, the weld so produced will be free of oxides and nitrides. WAT(11c)

World's Tallest Welded Building. ORVILLE ADAMS. *Welding*, Vol. 1, Nov. 1930, pages 903–906.

Describes some unusual methods used in the erection of the 19 story all-welded office building of the Dallas Power & Light Co. Some details are illustrated and the method of erection is discussed briefly. Ha(11c)

Welding Practice on Heavy Engines. ORVILLE ADAMS. *Welding*, Vol. 1, Aug. 1930, pages 674–677.

Discusses preheating, welding and calculation of costs for repairs to pistons, cylinder heads and cylinders of gas and Diesel engines. Ha(11c)

Comparative Examination of Progressing and Retrogressing Welding. (Vergleichende Untersuchung der Vorwärts- und Rückwärtsschweissung.) BARDTKE & MATTING. *Autogene Metallbearbeitung*, Vol. 24, June 1, 1931, pages 159–164; June 15, 1931, 175–178.

Comparative tests with left and right welding or, as it is better expressed according to the different hold on the welding torch, progressive and retrogressive welding, permit the conclusion that retrogressive welding is of considerable advantage for sheets of from 6 to 16 mm., both as regards quality and economy. For about 5 mm. thickness, both processes are equivalent. If progressive welding cannot be avoided, hammering in red hot state should be employed to improve the quality of the weld. The tests are described in detail and the economy calculations given. Ha(11)c

Repair of a Cylinder Block of a Truck by Welding. (Reparaturschweissung des Zylinderblocks eines Lastkraftwagens.) W. K. RAABE. *Autogene Metallbearbeitung*, Vol. 24, May 15, 1931, pages 147–148.

A crack in the cast iron of 20 cm. length opening into 2 of the cylinders was repaired by gas welding. The procedure is explained in detail. Ha(11c)

Arc Welding in the Locomotive Boiler Shop. I. JAS. M. VOSSLER. *Modern Machine Shop*, Vol. 4, July 1931, pages 11–14.

This installment deals with the preparation of boiler seams for welding and the various methods used in welding fire box seams. It is of great importance that the welder should have had experience as a boiler maker. Proper observation of heat condition to avoid contraction strains and waste of electrical energy is essential. Cross-sections of fire box welds illustrate the article. Ha(11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Melting and Heat Treating Sterling Silver. (Schmelz- und Wärmebehandling des Sterling-Silbers.) EDMUND THEWS. *Deutsche Goldschmiede-Zeitung*, Vol. 34, May 9, 1931, pages 196–198.

Copper in Ag increases the hardness and wear resistance, but introduced difficulties in melting and rolling. The alloy should be prepared by adding granulated Cu to a crucible and covering with Ag. The mass should be rapidly melted and heated to a temperature of 1200 or 1250° C. The melt is frequently covered with charcoal, which is replaced by potash some time before casting. Before casting the melt should be deoxidized with a small amount of Cd. Annealing is best carried out in an atmosphere of N_2 or CO_2. Contains 6 references. JLG(12a)

Slag Control Essential. FOLKE W. SUNDBLAD. *Iron Age*, Vol. 126, July 31, 1930, pages 289, 314–315.

Quality of metal is directly dependent on condition of the slag. Heat worked with thin slag at high temperature without addition of lime in final stage, product will be more satisfactory chemically than physically. Through the color, structure and density of solidified slag a true story is told of what can be expected of the heat both chemically and physically. The bigger the bath area the greater the necessity of having pure slag. Steel should be purified while in furnace rather than in ladles and molds. VSP(12a)

Mixed Gases in Oven-Hearth Furnaces. GEO. E. ROSE & F. M. WASHBURN. *Blast Furnace & Steel Plant*, Vol. 18, Sept. 1930, pages 1476–1479; Oct. 1930, pages 1621–1623; *Iron & Steel Engineer*, Vol. 7, July 1930, pages 394–400.

Paper read before the Association of Iron & Steel Electrical Engineers. MS(12a)

Steel Made without Manganese. Correspondence from ALBERT SAUVEUR, Cambridge, Mass. *Metal Progress*, Vol. 20, Aug. 1931, page 86.

Claims that zirconium is essential to produce good manganese free steel is refuted by the experience of American Rolling Mill. WLC(12a)

The Melting Process in the Cupola Furnace According to Views of Inventors. (Der Schmelzvorgang im Kupelofen nach Ansichten und Auffassungen von Facherfindern.) CARL REIN. *Giesserei-Zeitung und Giesserei*, Vol. 18, Jan. 9, 1931, pages 33–37; Jan. 16, 1931, pages 58–64; Jan. 23, 1931, pages 78–83.

A critical review of constructions, patents, advantages, etc. Ha(12a)

Relation of Manganese in Molten Iron to Manganese in the Molten Slag which Covers the Iron. G. OISHI. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 397–428.

In English. Attempts were made to determine the distribution constant with siliceous slag, "limey siliceous slag" and basic slag. Curves are given for manganese in metal and slag at different temperatures. HWG(12a)

Oxygen-CO Blast for Iron Furnace. Correspondence from E. ÖEHMAN, Stockholm, Sweden. *Metal Progress*, Vol. 19, May 1931, pages 87–88.

The writer gives an outline of a method of blast furnace operation designed to save charcoal. WLC(12a)

Melting Grey and Malleable Iron in the Indirect-Arc Furnace. J. C. BENNETT & J. H. VOGEL. *Foundry Trade Journal*, Vol. 44, June 4, 1931, page 371.

Paper read before the Chicago convention of the American Foundrymen's Association. See *Metals & Alloys*, Vol. 2, July 1931, page 135. OWE(12a)

Crucible Tool Steel Melting. OWEN K. PARMITER. *Metal Progress*, Vol. 20, July 1931, pages 55–58.

How Swedish Iron Is Made. J. A. LEFFLER. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published, 1931, *Mining & Metallurgy*, Part 1, pages 79–97.

Emphasis is placed on the purity of Swedish ore and fuel and on the care taken to avoid the presence of oxide in all Swedish iron and steel products. Composition of ores and fuel is given. The Sieurin method of making sponge iron at Hoganas is described. Blast furnaces are run at a slow rate. More iron is made in charcoal blast furnaces than in electric furnaces. The manufacture of Lancashire iron, Walloon iron and Uchatii crucible steel is described. Swedish acid Bessemer steel is a high carbon steel, not less than 0.65% C, and the carbon is caught coming down. Swedish open hearth steel is also acid, and caught coming down. Typical analyses are given for raw materials, products and slags and the various furnaces used are illustrated. HWG(12a)

Segregation in 80% Carbon Steel Ingots. E. ÖEHMAN. *Metal Progress*, Vol. 20, July 1931, page 86.

Reports electrical resistance study of segregation in .80% carbon steel. Method used for control of carbon in steel making. WLC(12a)

Refining in the Basic Open-Hearth. C. H. HERTY, JR. *Metal Progress*, Vol. 20, Aug. 1931, pages 58–63.

A paper to be presented before the Boston Convention of American Society for Steel Treating, September 1931, and to be published in greater detail with discussion in the Transactions. The author describes the basic open hearth process giving typical slag analyses and the time required for the various portions of the process. WLC(12a)

Vanadium Steel from Sponge Iron. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 20, Aug. 1931, pages 89–90.

The writer reports a double slag method of producing low phosphorus vanadium steel from sponge iron. WLC(12a)

Phase Equilibria in the Cr_2O_3–Al_2O_3 System. E. N. BUNTING. *Bureau of Standards Journal of Research*, Vol. 6, June 1931, pages 947–949.

A study of the phase equilibria in the Cr_2O_3–Al_2O_3 system has shown these oxides to be completely miscible in the liquid and solid states, with no compound formation. The melting point of Cr_2O_3 has been redetermined to be 2275° ± 25° C. Melting points of Cr_2O_3-Al_2O_3 mixtures

Mole percent Cr_2O_3	Solidus temperature ° C.	Liquidus temperature ° C.	Mole per cent Cr_2O_3	Solidus temperature ° C.	Liquidus temperature ° C.

WAT(12a)

Investigation of the Steel Making Processes on the Basis of the Physico-Chemistry. (Ueber den Ausbau der Erforschung der Stahlerzeugungsverfahren auf physikalisch-chemischer Grundlage.) H. SCHENCK. *Stahl und Eisen*, Vol. 51, Feb. 12, 1931, pages 197–202.

Report 202 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The article deals with the efforts to improve quality and economy of the steel mill products and points out that the chemistry of steel making has been neglected. Some examples of the unsolved problems are given and a program of investigation is outlined. GN(12a)

The System $MgO-FeO-Fe_2O_3$ in Air at One Atmosphere. H. S. ROBERTS & H. E. MERWIN. *American Journal of Science*, Vol. 21, Feb. 1931, pages 145–157.

The system $MgO-FeO-Fe_2O_3$ has been investigated at temperatures above 1000° C. on the isobar $^1/_5$ atmosphere O_2. In the binary system $MgO-Fe_2O_3$ no compound was found other than $MgO-Fe_2O_3$ which dissociates slightly on heating and begins to melt at 1750° C. ± 25°. Solid solution extends from this compound for a short distance toward MgO. In the binary system $FeO-Fe_2O_3$ the stable phase at temperatures below 1386° ± 5° is a hematite solid solution containing less oxygen than Fe_2O_3; just above 1386° ± 5° the stable phase is a magnetite solid solution containing considerably more oxygen than Fe_3O_4. The ternary system contains two solid solution fields. The first begins at MgO below 1000° and extends with increasing temperature, toward $MgO \cdot Fe_2O_3$ and FeO; a liquid phase appears at 1770° ± 25°; where the solid contains iron oxide equivalent to 73% Fe_2O_3. The second solid solution extends, with increasing temperature, from $MgO \cdot Fe_2O_3$ toward the iron oxide boundary which it reaches at 1386° ± 5°; solid solutions of about 1% MgO in $MgO \cdot Fe_2O_3$ are possible from 1750° to 1000° C. or below. Operation of an Open Hearth Furnace. Lesson 4. Reaction and Temperature. M. J. CONWAY (Lukens Steel Co.). *Iron & Steel Engineer*, Vol. 7, Aug. 1930, pages 425–428.

Author discusses the chemical reaction of the basic open hearth process giving heat records covering the elimination of carbon and phosphorus, and additions of lime, ore and deoxidizers. WLC(12a)

Duplexing. K. R. BINKS. *Iron & Steel Industry & British Foundryman*, Vol. 4, Mar. 1931, pages 194, 198.

A description of processes. CHL(12a)

Casting & Solidification (12b)

Steel Ingots. W. H. HATFIELD. *Metallurgist*, Jan. 1931, pages 8–12; Feb. 1931, pages 25–26.

This article is a review of the work of the "Heterogeneity Committee." This committee was appointed by the Iron and Steel Institute in 1924 and in 1929 was coördinated with the general industrial research scheme of the National Federation of Iron and Steel Manufacturers. It has published 3 reports in the Journal of the Iron and Steel Institute in 1926, 1928 and 1929. The First Report—1926—presents the results of a metallographic and analytical examination of a range of 16 ingots sectioned on the longitudinal axis. A section of the report was devoted to the mechanism of solidification from the theoretical point of view and a very complete bibliography was included. The Second Report dealt in a similar manner with a number of alloy steel ingots and also with tube, plate and free-cutting mild steel ingots. Ingot molds, non-metallic inclusions, temperature control and measurement, and casting conditions were discussed. The Third Report dealt largely with fundamental work which had appeared to be necessary as a result of the other investigations. Work was presented dealing with the liquidus and solidus of commercial steels executed by Andrew and Binnie at Glasgow Technical College, and on the solubility of iron and manganese sulphides in steel by the same investigators. Desch presented the results of research, conducted at Sheffield University, on the density of liquid iron and steel, while Lightfoot presented his initial report on a mathematical approach to aspects of the work which are difficult to attack experimentally. At present, the work is being continued under excellent conditions. Various types of ingots are being studied, and extensive further fundamental researches are in hand, and it is probable that a Fourth Report may be issued in the coming year. Liquid steel, when poured into the mold, is, obviously, at a temperature definitely higher than the freezing temperature. Assuming that it has cooled down to precisely the freezing temperature, it will probably be finally established that, in the change from the liquidus to the solidus phase, there is an increase in weight per unit volume of about 1.5%, i. e., a change over from an approximate specific gravity of 7.15 at the liquidus to 7.29 at the solidus. On the other hand, there is definite experimental evidence to show that, as the temperature of the liquid steel is increased, the weight per given volume becomes less; so much so that, to take a mild steel—0.2% carbon—having a freezing temperature of 1525° C. liquidus, to 1490° C. solidus ± 2° C., the following figures may be given with a fair degree of probability:

°C.	Vol. of 1 ton in cubic feet	Specific Gravity
1650	5.09	7.05
1600	5.06	7.09
1550	5.03	7.13

Moreover, as the steel continues to cool from the solidus point there is a continued increase in density probably as follows:

°C.	Vol. of 1 ton in cubic feet	Specific Gravity
1490	4.92	7.29
1450	4.90	7.31
1400	4.88	7.34
1300	4.85	7.39
1200	4.82	7.44
1100	4.78	7.49

The actual mechanism in the mold of the freezing process, the variation of temperature as it proceeds, the possibility of convection currents set up by the differential cooling, of change in viscosity of the steel, of the movement of the steel in the interstices between the partly formed crystals, and the rate of rise and fall of any suspended solid matter are still unknown and are experimentally extremely difficult to determine at a temperature range as high as 1450° to 1650° C. If one carefully studies the freezing of an ingot in the mold, one finds that very shortly after the formation of the outer frozen shell, this shell separates from the walls of the mold, and thus a space is interposed with its insulating effects—modification of radiation, conduction and convection phenomena—between the freezing ingot and the mold. How does this affect the passage of heat from the steel through the mold? What are the thermal conductivity values of the cast iron of the mold, or of the material of the ingot in these ranges of temperature? When steel freezes, latent heat is evolved; what is the effect of this? Lightfoot has made a mathematical analysis of this point. The conclusions of the Committee on solidification in the solid type of ingot are set forth. In regard to segregation the author says, "A survey of these figures indicates clearly that the C, S and P segregates to a considerable extent and together, while the Mn and Si segregate to a less degree. The detailed analyses from the sections of the numerous ingots studied by the Committee confirm this behavior of the several elements as regards different concentration in the various zones of the ingots. The differential freezing effect and the manner in which the solid steel is built up from the liquid, do not produce heterogeneity of note as regards the manganese and silicon, and this is also found to be the case with Ni, Cr and Cu. One very important feature is that the Mn and S, which are understood to exist in the final ingot as MnS, do not segregate in the proportions necessary to constitute the compound, and this leads to the deduction that when the differential freezing effect causes concentration of S, it is probably as FeS, which is soluble, and not as MnS, which is presumed to form at a late stage by reaction between the FeS and the Mn in the steel. Some of the variation in the Mn content which is noted, may be due to the fact that some of the Mn is associated with the C as a double carbide of Fe and Mn. VVK(12b)

Casting Guns by the Centrifugal Process. T. C. DICKSON (Watertown Arsenal). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 212–240.

A paper presented before the 12th Annual Convention of the Society, Chicago, September 1930; includes discussion. The author describes the machine used at Watertown Arsenal for casting gun tubes centrifugally in chill molds. Tubes properly cast show no shrinkage cavities and are slightly denser than forgings of the same composition. Strain rings show the outside is under tension, falling off to a neutral point about two-thirds the way to the bore from which point the compressive strain increases to a maximum value at the bore. This condition is not removed by heat treatment and higher pressure is necessary to cold work the bore of centrifugal castings than for forgings. Analyses taken across the section show an appreciable increase in carbon toward the bore (.32–.52% C), a slight increase in manganese toward the bore (.60–.68% Mn), a similar increase in molybdenum, fairly uniform silicon content, phosphorus and sulphur also show slight increases of .015–.022 and .022–.30%, respectively, from outside to bore but the content is well within permissible limits. Ladle analysis C .35%, Mn .61%, Si .245%, P .016%, and S .028%. The increased carbon at the bore makes for higher proportional limit where it is most needed, the pressures developed in a gun tube are greatest at the bore surface. Experience shows centrifugal castings can be worked to twice the percentage of enlargement of the bore permissible with forgings. Features of gun manufacture from forgings resulting in heavy machine costs and metal losses not entailed when centrifugal castings as used are discussed. Macrographs of centrifugal castings are shown, physical property tests, and service tests on several barrels made in this way are detailed. Metallurgical advantages of the processes are high proportional limit at the bore where needed, higher tensile and Charpy properties for the same composition, initial compression of the metal at the bore, denser, sounder metal, and ability to take more drastic cold work than forgings of the same composition. Economical advantages are the elimination of 35% ingot discard, elimination of heating for forging and heating of the forging, half as much metal required, less plant and equipment required, time of production shortened and reduction in the cost of manufacture. WLC(12b)

Standardizing Die-Casting Alloys and Machines Aids Industry. CHARLES PACK. *Steel*, Vol. 87, Nov. 6, 1930, pages 47–49; Nov. 20, 1930, pages 55–56, 59.

Discusses developments in the die-casting industry, factors to be considered in the purchase of die-casting equipment, and die-casting costs. MS(12b)

A Contribution to the Study of Fluidity. (Contribution a l'étude de la coulabilite. Applications à la fonderie de l'aluminium, de l'alpax, des alliages legers d'aluminium avec quelques essais sur le zinc.) ANDRÉ COURTY. *Revue de Métallurgie*, Vol. 28, Mar. 1931, pages 169–182; Apr. 1931, pages 194–205.

The fluidity of aluminum alloys and of zinc was studied in reference to their composition, time of pouring, pressure created in pouring, dynamic effect produced and the state of the surface. Alloys used consisted of alpax, some binary alloys with Si, Cu, Zn and Ni, a few modifications of alpax to which Cd, Mg, Ni, Cu, Zn and Mn were added. Commercial Al and Zn were tried. For testing the spiral mold in its final modifications as recommended by L. Guillet and A. Portevin was employed. (Full description given.) When it was found that for reproduction of the results pouring must be done under a constant pressure, the metal must be quiet at the point of entering the spiral proper, feeding must be conducted even when the metal is almost at the solidification point and the dross should be eliminated as much as possible, these features were incorporated into the apparatus. After standardization of the testing condition the characteristic properties of alloys were studied and the influence of the thermal treatment of molten metal investigated. Modification of alpax with sodium does not change its fluidity nor does the overheating or time held at the temperature before casting, provided the same temperature is used for the latter. The casting temperature increases the fluidity rapidly, particularly for alpax. Zinc is more sluggish in this respect. The speed of filling the spiral can be measured by short circuiting the cast metal with properly located wires. Heating of the mold between 578° and 750° C. showed that the fluidity of alpax increases according to an equilateral hyperbola in which the temperature is an ordinate. For alpax, aluminum and zinc the fluidity remains proportional to the casting pressure whatever the temperature might be. Covering the walls of the chill with liquids barely affects the fluidity while solid coatings like soot increase it. The chemical composition of aluminum alloys has a certain influence on their fluidity. In the realm of solid solutions the fluidity of Al appears to diminish with the increase of the alloying elements. Si gives them a high fluidity. Cu in Al-Cu alloys increases fluidity until its content is 8%. With low Ni and Cd contents they have the same beneficial action on alpax. Mg in amounts higher than 4% improves the fluidity of Al alloy containing 13.2% Cu. JDG(12b)

Mold Materials. (Formen-Baustoffe.) WILLI CLAUS. *Metallwirtschaft*, Vol. 10, May 8, 1931, pages 369–374.

Contains 14 references. Tables are given for the thermal properties such as melting point, specific heat in the solid and liquid state, and thermal conductivity of a large number of metals, inorganic, organic solids and liquids. Directions are given for estimating the thermal properties of alloys from the properties of their constituents and the constitutional diagrams. Molds are divided into permanent and single molds. In all cases the melting point of the mold must be higher than the pouring temperature of the metal. In choosing a mold material for a metal the necessity of producing a definite crystal structure, the elimination of porosity and the gas content of the metal should be considered. Thermal conductivity influences crystal structure. Sometimes a mold consists of two materials of different conductivities. In calculating the thermal capacity of a mold to obtain a definite cooling rate, the equilibrium temperature between mold and casting must be considered. By properly adjusting the cooling rate some metals can be made considerably denser. However, if pure aluminum is cooled too rapidly, the dissolved gases do not have a chance to escape. For alloys in which diffusion takes place during solidification low conductivity materials such as sand are best. Cu-Sn bronzes are an example of this group. Alloys which segregate due to insolubility of the components, such as Cu-Pb, require rapid cooling. Alloys in which structural changes take place during solidification are cast in the type of mold required to produce the desired structure. Although permanent molds are protected with coatings they are attacked by the liquid metal. Sand is used almost exclusively for single molds. The permeability determines the rate of gas escape and it must have sufficient strength to withstand the force of the liquid metal. CEM(12b)

The Degasification Process. J. E. HURST. *Foundry Trade Journal*, Vol. 44, Apr. 9, 1931, pages 264–265.

Describes early experiments designed to produce sound castings by promoting the removal of gases from the liquid metal and finally deals with a new process introduced at the plant of Messrs. Bradley and Foster, Limited. A photograph of the Bradley degasification apparatus accompanies the article, together with two diagrams of earlier methods of accomplishing this object. OWE(12b)

The Scientific Production of Non-Ferrous Ingots. WALTER H. JACOBSON & WILLIAM KELLY. *Metal Industry*, London, Vol. 38, May 1, 1931, pages 453–455.

The various advantages of using brass and bronze ingots made from secondary metals under close chemical control and microscopic and macroscopic examination are mentioned. A table of the chemical specifications for the 15 alloys recommended for non-ferrous ingots is given. PRK(12b)

Shrinking of Alloys. (Ueber die Schwindung von Legierungen.) FRIED. BOEHM. Doctor's Thesis published by Giesserei Verlag, Düsseldorf, 1930, 12 pages.

Tests to determine the shrinkage of a series of copper-tin alloys were made under conditions as they occur in practical foundry work, with variable cooling velocity and in various gas atmospheres. The total shrinkages can be calculated, with good approximation, with simplifying assumptions from the densities and expansion coefficients of the material. The changes of state corresponding to the diagram of state under these conditions are well expressed by the shrinkage curves. The solid solutions play an important part in the changes in shrinking. The shrinking of white raw iron has been determined for the first time. The arrangement of the tests and their results are given in detail. Ha(12b)

Die Casting Zinc and Aluminum. D. L. COLWELL(Stewart Die Casting Corp.). *Metal Progress*, Vol. 18, Nov. 1930, pages 58–63, 100.

Various researches on zinc die-casting alloys show aluminum, lead, cadmium and tin making trouble in the form of swelling, cracking, and warpage. Copper, nickel, and particularly magnesium act as antidotes for this condition. Methods of test are described and the program of A. S. T. M. on this subject and some of the data from it are discussed. WLC(12b)

Die Casting Brass and Other New Alloys. CHARLES PACK. *Metal Progress*, Vol. 20, July 1931, pages 72–78, 100.

A discussion of composition and defects in commercial die casting alloys of zinc and aluminum base with data on their properties and applications. New die casting alloys, magnesium base, cadmium base and copper base, are described and applications discussed. WLC(12b)

A Study on the Cast Iron Ingot Mold. T. NISITU. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 389–390.

In English. An iron of 3.3 to 3.8% total C, 1.5 to 2.0% Si, 1.3 to 1.8% Mn, 0.15% P and 0.07% S is suggested. Segregation of manganese sulphide is to be avoided. Casting should be rapid and the casting should self-anneal in the sand and then be transferred hot to the annealing furnace for 5 to 10 hrs. anneal at 700–800° C. In use, mold life is lengthened by proper preheating, low pouring temperature and moderate teeming rate and quick stripping. High carbon steels shorten mold life. HWG(12b)

The Effect of the Ingot Temperature on the Location of Blow Holes and the Segregation of Soft Steel Ingots. (Der Einfluss der Kokillentemperatur auf die Lage der Randblasen und auf die Seigerungsverhältnisse in weichen Flussstahlbrammen.) A. STADELER & H. J. THIELE. *Stahl und Eisen*, Vol. 51, Apr. 9, 1931, pages 449–460.

Report No. 205 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. 8 references. The results of investigations of the location of blow holes in 200 kg. and 3500 kg. ingots cast in either cold or pre-heated molds are reported. It is shown that there exists an effect of the mold temperature on the locaiton of the edge blow holes which were observed only in the heavy ingots. A favorable location of the edge blow holes, i. e., rather far from the surface of the ingot, is observed either at low ingot temperatures around 60° C. or at high temperatures above 500° C. The pouring in ingots heated to 500° C., however, is practically impossible. In small ingots no edge blow holes are observed under the normal practice. The small ferrostatic pressure is the reason for this occurrence. Streaks of segregations were discovered by metallographic investigations in both the small and big ingots. Explanations as to the origin of these streaks are given. No uniform effect of neither the cold nor pre-heated ingots upon the segregation could be detected. GN(12b)

The Casting of German Silver in Water-Cooled Chill Moulds. OTTO JUNKER. *Metal Industry*, N. Y., Vol. 28, Nov. 1930, pages 517–518.

Adapted from an article in *Metallwirtschaft*. Results bared on continuous working experience, definitely prove the economy of casting. German silver sheet slabs in water cooled chill molds. See also "Centrifugal Casting of Metals," *Metals & Alloys*, Vol. 1, Mar. 1930, page 430. VSP(12b)

Investigation of Chilled Roll. T. KIKUTA. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 79–115. In Japanese. Brief English abstract.

Mathematical study of cooling rates of chilled rolls of different diameters cast in chill molds of different thicknesses at different temperatures. HWG(12b)

Modern Steel-Pouring Plant. Some Characteristic Plant Layouts. K. R. BINKS. *Metallurgia*, Vol. 4, June 1931, pages 39–41.

Description of pouring equipment and some layouts in tonnage plants. JLG(12b)

Aluminium Sheet Production. ROBERT J. ANDERSON. **Part 6. Ingot Moulds.** *Metallurgia*, Vol. 13, Apr. 1931, pages 213–214; **Part 7. Ingot Pouring Practice.** May 1931, pages 15–16; June 1931, pages 63–65; **Part 8. Pre-treatment of Rolling Ingots.** July 1931, pages 85–88.

Part 6. Contains bibliography of 12 references. Tilting vertical book molds are generally used. A closed grained gray iron makes good molds. Molds usually fail by cracking or checking. The author favors the use of molds having polished faces. No mold dressing is necessary. Part 7. A detailed description of methods of pouring aluminum ingots that are to be rolled into sheet. 6 references. Part 8. Al alloys must be broken down hot. Some can be rolled immediately after they have cooled to a suitable temperature, but others must be maintained at an elevated temperature several hours before rolling. Preheating is the best practice for all alloys. Alloys may be scalped before rolling or after a slight reduction. Heating furnaces and scalping machines are discussed. 2 references. JLG(12b)

Rolling (12c)

Plain Bearings in Rolling Mills. (Gleitlager an Walzwerken.) W. ROHN. *Zeitschrift für Metallkunde*, Vol. 23, Mar. 1931, pages 76–86.

Includes discussion. It is stated that the wear on journals and bearings increases very rapidly with increasing rolling pressures. This wear can now be almost entirely prevented by cooling the bearing, best by copper tubes included in the bearing body. The discussion and illustrations furnish considerable engineering information. RFM+EF(12c)

Automatic Pressure Lubricating Systems for Roll Necks. M. RESWICK. *Iron & Steel Engineer*, Vol. 7, Oct. 1930, pages 503–505.

The author gives the advantages of automatic lubrication of roll necks and outlines the principles of several systems. WLC(12c)

Group Versus Individual Driven Rolling Mill Stands. R. H. ELLIS. *Iron & Steel Engineer*, Vol. 7, Aug. 1930, pages 429–431.

The author shows the mechanical advantages of group driving, the proper combinations thereof, and of individual drive. The nature of the product makes individual drive necessary on certain sheet, merchant and strip mill jobs. WLC(12c)

Modern Rolling Mills for Non-Ferrous Metals. (Neuzeitliche Walzwerke für Nichteisenmetalle.) E. PFANN. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 391–392.

Rolling mills with large rolling pressure. Largest equipment of this kind built for non-ferrous metals is described and illustrated. EF(12c)

Influence of the Degree of Rolling, Rolling Temperature and Cooling Conditions on the Mechanical Properties of Low-Carbon Steel. (Einfluss des Walzgrades der Walztemperatur und der Abkühlungsbedingungen auf die Mechanischen Eigenschaften von kohlenstoffarmen Flussstahl.) A. POMP & E. FANGMEIER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, May 23, 1931, pages 666–668.

Tests were conducted on bars of 0.08 C which were rolled from different initial thicknesses to the same final thickness. From the tests, it was concluded that the most favorable value of mechanical properties were always found at a rolling temperature of 900° to 1000° C.; at this point, the figures of normalized steel were equaled or even exceeded. For temperatures higher than 1100° C., overheating phenomena are observed which reduce the mechanical properties. At temperatures lower than 900° C., a reduction is also observed; although below 700° C., tensile strength, elastic limit and hardness are increased, while elongation, notch-toughness and grain size are decreased. Ha(12c)

Rolling Mill Lubrication. E. S. GLAUCH. *Iron & Steel Engineer*, Vol. 8, May 1931, pages 215–221.

The author covers the recent changes in rolling mill lubrication, description of special machinery erected for determining the coefficient of friction with various lubricants and the results of tests conducted on these machines showing that with proper selection of grease, savings as high as 25% could be made on power. WLC(12c)

Roll Pass Design. Part XXV. W. TRINKS. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 35–38, 50.

Collars are designed in blooming mill rolls to insure proper entrance of the semi-finished bloom and to protect against cracking of the steel. Width of collar at root about equal to depth, which seldom exceeds 3 in. Collar may taper 10 degrees. Diameter of roll at bottom of grooves must be kept almost constant. Number and size of grooves dependent on size of ingot and size of bloom desired. In general, a 20 × 20 in. ingot may be rolled to an 8 × 8 in. bloom in 3 grooves or to a 4 × 4 in. bloom in 5 grooves. Belly necessary on rolls to counteract central spreading of ingot in subsequent passes as surface becomes colder than the interior. JN(12c)

Investigations of Rolling Mill Furnaces. (Untersuchungen an Walzwerksofen.) L. A. RICHTER. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, pages 377–385.

Report 149 of the Committee on Heat of the Verein deutscher Eisenhüttenleute. The article summarizes the data of investigations of rolling mill furnaces, compiled by the "Eisenhütte Oestereich" and obtained from rolling mill furnaces in Austrian steel plants. The furnaces investigated and methods of operation are described. Data of the heat balances and the material losses by oxidation are given. Relations between consumption of heating coal and production are established, as well as the relations between heat losses during the idling period and production. The relations between the surface area of the furnace and area of the hearth are dealt with. The heat consumption during the preheating period of the furnaces investigated and its dependence upon furnace surface area and hearth area is mentioned. GN(12c)

Manufacture of Cast Iron Rolls. (Die Herstellung von Gusseisen-Walzen.) E. PEIPERS. *Stahl und Eisen*. Vol. 51, Mar. 19, 1931, pages 345–351.

Report 83 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Including discussion. The article discusses the production and properties of plain cast iron rolls as well as chilled cast iron rolls for the various types of rolling mills. Special reference is made to the manufacturing of chilled iron rollls according to the two methods by Peipers and Weymerskirch. The composition of alloyed chill cast iron rolls is given. The composition of two American types of alloys for chilled iron rolls, Phoenix Metal and Adamite is mentioned. GN(12c)

Developments in the Design and Application of Antifriction Bearings to Rolling Mills. W. B. MOORE. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 27–34.

Recent developments in tapered roller bearings concerned with applications to new types of mills and with improvements in mounting practice. Correct mounting design requires close pass alignment, resistance to thrust as well as radial loads, easy assembly and disassembly, and perfect lubrication. Moore describes and illustrates with photographs and diagrams a standardized antifriction bearing mounting developed for steel mill roll necks with several adaptions for various special types of mill. Also describes and illustrates a standard mounting developed for pinion stands. JN(12c)

The Development of the Production of Thin Sheets of High Quality. (Das Feinblech in der Entwicklung zur Qualität.) H. KLEIN. *Stahl und Eisen*, Vol. 51, Feb. 12, 1931, pages 189–196.

The article considers, in a general manner, the development of sheet mills, application and requirements of sheets, selection of sheet bars and rolling procedure, various types of annealing and equipment, pickling, dressing, testing and packing of sheets. The various types of metal coating are considered. A résumé is given on the application of new types of steel for sheets, as stainless steels, copper steels, Armco-iron etc. Statistics on the consumption of sheets in the most important iron producing countries are included. GN(12c)

Recent Developments in Rolling Mill Table Construction. WILLIS MCKEE. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 23–26.

Most rolling mill tables formerly built with line shafts and bevel gear drives. Other early tables built with rope drives of wire or hemp. Cut gears and roller bearings introduced in recent years. Describes the two principal designs of overhung individually electrically driven rollers recently developed. Also describes the "Motor Roller," a new individually electrically driven table roller with an inbuilt motor. The motor revolves around a shaft that is held against rotation. The unit is self-contained, has no overhanging parts and requires very little space. The use of individually driven rollers eliminates the necessity of maintaining accurate table alignment. Magnetic rollers have proved very satisfactory for transporting steel whose temperature is not above 1200° F. JN(12c)

Resistance to Deformation and Flow of Material During Rolling. (Formänderungswiderstand und Werkstoffluss beim Walzen.) A. FALK & E. SIEBEL. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, pages 388–390.

Discussion of the above authors on E. Siebel's article in *Stahl und Eisen*. Vol. 50, 1930, pages 1769–1775. See "Investigation of the Resistance of Deformation of Low Carbon Steel in Hot Rolling between 700° and 1200° C.," *Metals & Alloys*, Vol. 2, June 1931, page 115. GN(12c)

Developments in Thin Gauge Strip and Sheet Production Methods. LLOYD JONES. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 43–45.

Discusses early attempts and recent developments in ferrous and non-ferrous production of light gage sheets and wide strip by continuous methods. The continuous hot strip process is suitable for any width of material but is uneconomical for thicknesses below 16 gage. For lighter gages, the material from the hot strip mill is finished by hot rolling in standard sheet and tin mills or by cold rolling in single or continuous cold mills. The writer has developed a new pack rolling process (U. S. Patent 1,680,522, Aug. 14, 1928) for hot strip which produces material as thin as 22 gage in widths up to 36 in. and promises the possibility of continuous hot rolling to any gage desired. JN(12c)

Cold Roll Forming of Metals. Part XII. D. A. JOHNSTON. *Metal Stampings*, Vol. 4, Jan. 1931, pages 25–28.

Discusses in detailed two manufacturing methods in cold roll forming practice and illustrates the rolls used in the manufacture of the door buck by each method. The first method uses ten sets of rolls to form the piece and a press brake at the end to complete the two 90° bends required. The second method completes the door buck with all bends in one rolling operation on a 16-spindle rolling machine, thereby materially reducing production costs. JN(12)

The Application of Pressure Lubricating Systems to Blooming and Continuous Mills. W. D. HODGSON. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 47–50.

Describes and illustrates typical installations of a mechanical pressure lubricating system for rolling mills. System consists essentially of one or more pressure grease tanks with a number of grease lines extending to the lubricator valves on the mill. The grease supply is regulated by means of compressed air. The air line is equipped with one or more solenoid air valves operated from an electric control panel. Any number of different greases may be used in the same system, requiring only separate grease tanks. The advantages of this system are: positive lubrication of inaccessible parts, removal of hazards of manual greasing, flexibility in adding additional units as required, adaptability to unusual installations, and use of multiplicity of greases in same system. JN(12c)

On the Rolling of Special Steels in Blooming Mills with Examples of the Pass Design. (Ueber das Auswalzen von Sonderstählen auf Blockstrassen mit Kalibrierungsbeispielen.) O. EMICKE. *Stahl und Eisen*, Vol. 51, Apr. 2, 1931, pages 417–428.

The article deals in detail with the effect of the resistance to deformation, the heat conductivity and the rolling temperature on the particular rolling condition of special steels. Special reference is made to the shapes of ingots used and their weights. Finally follows a discussion of the design of passes of blooming mills for this special purpose. The pass designs of reversing two-high blooming mills as well as of three-high mills are discussed. GN(12c)

Rolling Metal Foil. C. E. DAVIES. *Metallurgia*, Vol. 3, Feb. 1931, pages 141–143; Mar. 1931, pages 181–182.

Lead, tin or aluminum foil can be rolled as thin as 0.00025 in. The latter metal is the most difficult to roll because it hardens during rolling. Formerly thin foils were produced by pack or "book" rolling, but they are now produced in coils from 15 to 20 in. wide and weighing 100 lbs. Some of the mills used for foil rolling are described. JLG(12c)

Forging (12d)

Press Working and Forming of Metals. Part XXXII. The Hot Press Forging of Brass. E. V. CRANE. *Metal Stampings*, Vol. 4, Jan. 1931, pages 39–42, 72.

Lists α, β and γ phases of alloy brass with properties of each. Gives temperatures of forging required in practice for various compositions of brass and properties encountered. It is desirable in forging practice to use a blank which almost fills the die. This results in reduction of scrap loss and increased die life. Trimming of brass forgings is usually done cold. A number of small press forgings are illustrated. JN(12d)

Manufacture of Large Weldless Forged-Steel Pressure Vessels. JOHN L. COX. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, 1930, *Iron & Steel*, pages 49–60.

Includes discussion. Describes in detail the various steps taken in the manufacture of large weldless forged-steel cylinders for high-pressure boiler drums and for various uses in the oil-refining and chemical industries. It covers the melting, casting and heating of the ingot; cutting-off, piercing and expanding the billet; forging, treating and machining the cylinder; and illustrates a number of ways in which the ends of the cylinder can be closed. (12d)

Shearing & Punching (12e)

Construction of Sectional Round Blanking Die. EMIL PANEK. *Metal Stampings*, Vol. 3, Sept. 1930, pages 829–831.

Describes procedure for constructing a die of the 6 section type, in which the tool steel die parts are backed up by cast-iron blocks, cast integral with the shoe. Advantages are use of comparatively inexpensive materials, easy heat treatment, and readily replaceable sections. MS(12e)

Extruding (12f)

The Influence of Pressure and Temperature on the Extrusion of Metals. C. E. PEARSON & J. A. SMYTHE. *Journal Institute of Metals*, Vol. 45, No. 1, 1931, pages 335–381.

Includes discussion. See *Metals & Alloys*, Vol. 2, July 1931, page 135. (12f)

Progress in Extruding Metals. E. PFANN. *Metal Industry*, N. Y., Vol. 29, June 1931, pages 251–253.

The development of the light metal industry has led to the manufacture of heavy extrusion presses ranging from 2500 to 5000 tons pressure. For the extrusion of concentric tubes, there is a patented method of supporting the container so that alignment of axis of container with stem and piercing mandrel is possible. PRK(12f)

Machining (12g)

Machining of Aircraft Cylinder Barrels. C. H. DECKARD. *Western Machinery World*, Vol. 22, Aug. 1931, pages 345–347.

The methods and operations adapted by the Wright Aeronautical Corporation for accurately machining cylinder barrels for air cooled engines is described. There are eleven operations necessary to complete these forgings. These are as follows: 1. Rough turn outside diameter. 2. Load, bore, face, undercut and champer. 2A. Bore, turn, face, champer, form angle. 3. Form taper, turn two dias. face. 3A. Turn face and form taper. 4. Turn 36 fins and form undercut. 5. Heat treat. 6. Face ends, turn angles. 7. Mill threads. 8. Grind $^5/_8$ inch dimension taper. 9. Burr fins, break sharp edges. 10. Wash and clean. 11. Inspect, deliver to stock. Each operation is described in detail. WAT(12g)

Turning with Shallow Cuts at High Speeds. H. J. FRENCH & T. G. DIGGES. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 2, 1930; *Machine Shop Practice*, pages 55–86.

Includes discussion. In this paper a method is described for testing lathe tools under shallow cuts and fine feeds. See also *Metals & Alloys*, Vol. 1, Apr. 1930, page 476. (12g)

Cemented Tungsten Carbide. GREGORY J. COMSTOCK (Firth-Sterling Steel Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 993–1008.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion. The history of the development of tungsten carbide is traced, the method of preparation is described and the characteristics of different grades discussed and illustrated by micrographs. Application of different grades to various machining operations are discussed with reference to present uses and future development of the field for this tool material. WLC(12g)

Power Measurements on a Hack-Saw. (Leistungsversuche an einer Bügelsäge.) W. HALLICH (Tech. Hochschule, Dresden). *Berichte über betriebswissenschaftliche Arbeiten* (V. D. I. Verlag, Berlin), Vol. 2, 1929, pages 20–33, 12 figures.

Tests on a power hack-saw, cutting 0.44% C steel of 92,000 lbs./in.^{2} tensile, with cobalt-chrome hack-saw blades. Effects of pressure, of speed, and of the number of teeth to the inch, were studied, and are shown in many complex diagrams. HWG(12g)

Modern Cutting Tools for Machine Tools. J. B. RENNIE. *Edgar Allen News*, Vol. 9, Dec. 1930, pages 769–772; Jan. 1931, pages 785–788; Feb. 1931, pages 812–813.

Effect of cutting speed on hardness and tensile strength of material to be cut; power consumed in cutting medium steel and ordinary cast iron on a lathe; tempering and secondary heat treatment; hardening prior to secondary heat treatment; welding high speed steel tips on shanks; tool edges with or against grain; shank material; lack of recognized test for high-speed steel hardness; induced hardness of the work material in path of tool by cutting tool, are among subjects discussed in January instalment. February instalment illustrates 39 shapes of tipped tools, arranged in sets, and includes recommendations. MFB(12g)

Machineability of Steel. (Die Bearbeitbarkeit des Stahles.) F. RAPATZ, with discussion by K. KREKELER & H. STÄGER. *Schweizer Verband für die Materialprüfungen der Technik*, Report No. 47 of the *Eidgenossische Materialprüfungsanstalt* (Report of discussion No. 18) Nov. 1929, 30 pages.

A general explanation of the variables entering into the machinability of steel, including effect of structure, of speed, feed, cutting oil, heat-treatment of high speed tools, etc. Photographs of surfaces produced under different cutting conditions are shown. Hardness-temperature curves for carbon tool steel, high speed steel and tungsten carbide are given. Discussion centers largely around cutting oils. This is a sort of correlated abstract in itself, and is not suited to further abstracting. HWG(12g)

The Probable Speed of Machining. A. H. RODRICK. *American Machinist*, Vol. 74, Feb. 19, 1931, pages 307–309.

Discussion of the speed of cutting of various metals, depth of feed, lubrication and grinding of cutting tools. Gives a chart showing best probable speeds for cutting metals. RHP(12g)

The Machining of Aluminum Alloy Castings. (Die Bearbeitung von Aluminium-Gusslegierungen.) W. LINICUS. *Metallwirtschaft*, Vol. 10, May 22, 1931, pages 424–426.

Contains 6 references. The necessity for using tools of different shape for aluminum alloys from those used for heavier metals and different machining practice are explained. The main differences are small cutting angles and high cutting speeds. Suitable tools and practice are described in detail for turning, milling, filing, shaping, sawing, threading, drilling, broaching, grinding and polishing aluminum alloys. CEM(12g)

The New Alloys and Machine-tool Design. Part 4. Hand-actuated Work-holding Devices. FRANCIS W. SHAW. *Metallurgia*, Vol. 3, Apr. 1931, pages 209–212.

A description of various chucks. JLG(12g)

New Developments in Machining Aluminum and Its Alloys. R. L. TEMPLIN. *Metal Stampings*, Vol. 3, Oct. 1930, page 922.

Abstract of paper read before the Society of Automotive Engineers, Oct. 7–8, 1930. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 43. MS(12g)

The Influence of Chemical Composition and Heat Treatment of Steel Forgings on Machinability with Shallow Lathe Cuts. T. G. DIGGES. *Bureau of Standards Journal of Research*, Vol. 6, June 1931, pages 977–992.

The tests described in this report were made primarily as a study of lathe-tool performance with shallow cuts as affected by variations in chemical composition and heat treatment of the steels cut. The cutting tests were made dry with high-speed steel tools of a selected size, form, composition and heat treatment, with a feed of 0.0115" per revolution and 0.010" depth of cut. Comparisons were made of the Taylor speeds on the basis of equal tensile strengths when cutting 0.4% C (S. A. E. 1040), Cr-V (S. A. E. 6140), Ni-Cr (S. A. E. 3140 and 3435), Cr-Mo (S. A. E. 4140) and $3^1/_2$% Ni (S. A. E. 2340) steel forgings heat treated to give tensile strengths between 75,000 and 220,000 lbs./in.^{2}. This study also included consideration of the surface finishes of the various steel forgings as affected by the test conditions, the microstructures of the steels cut, and tool performance as affected by the additions of 3.5 to 11.7% Co to the customary 18% W type of high-speed tool steel. If machinability is measured by the cutting speed permitting the tools to last a definite time, then measurable differences were observed between the various steels cut in the lathe test with shallow cuts. The fact, however, that some given steel permits a higher cutting speed than another steel for some tensile strength which is the same for both materials does not necessarily indicate that the 2 steels maintain the same relationship for another tensile strength. Of the different steels cut in the lathe tests the plain carbon steel was the most difficult to machine other than an annealed Ni-Cr steel. The surface finish on the plain carbon steel was also considered to be inferior to that of the alloy steels. The results showed that the effect of changes in chemical composition of steel forgings upon their cutting speeds was dependent upon the tensile strength at which the comparisons were made. In the different steels cut with shallow cuts the most effective special alloying elements for improving machinability were the combinations of Ni and Cr or Cr and V for the high tensile strengths in the neighborhood of 180,000 lbs./in.^{2}, while Cr and Mo were the most effective in the lower range of about 90,000 lbs./in.^{2} WAT(12g)

Drawing & Stamping (12h)

How to Select Thin Plate for Deep Drawing. H. T. MORTON (Hoover Steel Ball Co.). *Metal Progress*, Vol. 18, Dec. 1930, pages 54–59.

Causes of defective automotive stampings are given as quality of steel, die design and machine set-up. The author's studies with material 0.250–0.300 inches thick is reported. Methods of test and control are discussed. Methods of finishing and annealing were studied. Guides to deep drawing quality are found in tensile strength and elongation. Surfaces must be free from seams, laps, scratches and decarburization. The steel must be clean, micrographs illustrate. WLC(12h)

Experiments in Wire-Drawing. Part I. Behavior of a Composite Rod. W. E. ALKINS & W. CARTWRIGHT (Thomas Bolton & Sons, Ltd.). *Institute of Metals, Advance Copy* No. 561, Oct. 1931, 11 pages.

In order to study the flow of metal during drawing, composite Cu rods were produced by drawing several tubes over a solid core. After annealing these composite rods were drawn in straight-sided dies of various tapers and the relative reduction of each layer determined. The percentage reduction of each layer was the same, and therefore equal to the percentage reduction of the rod as a whole. Further examination indicated that during drawing the boundary surface of each layer was a frustrum of a cone and that all such cones had a common axis and a common apex. The loci of incipient reduction, of equivalent stages of reduction, and of complete reduction were found to be a series of spherical caps, radially parallel to one another and bounded by the bearing of the die. Furthermore, all of these caps had a common center, which corresponded with the apex of the cone formed by the bearing of the dies. 4 references. JLG(12h)

Experiments in Wire-Drawing. Part II. Notes on the Relation between Reduction of Area by Cold-Drawing and Tensile Strength of H.-C. Copper. W. E. ALKINS. *Institute of Metals, Advance Copy* No. 562, Oct. 1931, 9 pages.

When tensile strength is plotted against percentage reduction of area a straight line up to about 15% reduction results. Above this the curve has the form of a rectangular hyperbola, one asymptote of which lies at 32.6 tons/in.^{2} When reductions are made by a series of draws rather than by one draw the tensile strength is less. For a single draft a 56% reduction was possible, but with more than one draft not over 40% reduction could be obtained at each draft. 1 reference. JLG(12h)

Aluminum Sheet for Stamping and Drawing. Part 11. R. J. ANDERSON. *Metal Stampings*, Vol. 4, Jan. 1931, pages 31–34.

The various tempers of aluminum sheet are produced by annealing and subsequent reduction in thickness by cold rolling at constant width. The system of temper classification is based on tensile properties and hardness. A. gives system of nomenclature for standard aluminum sheet with table of Shore scleroscope hardness for different tempers and gages. The greater the amount of deformation suffered in fabrication, the softer the material required. Consumers should adhere to standard tempers in the interest of shop standardization. The temper of the finished aluminum article is also influenced by the annealing methods employed. Coil and flat sheets usually annealed by batch methods while circles are best annealed in continuous furnaces. A. suggests routine tests for drawability and grain size in using aluminum sheet. JN(12h)

Construction and Operational Features of Four-Post Presses. FRED R. DANIELS. *Metal Stampings*, Vol. 4, Jan. 1931, pages 51–54, 67–68.

Complete, detailed description of principles, design, construction, theory, operation, special features and advantages of the four post press for metal stamping. JN(12h)

Die Pressing Brass and Copper Alloys. JOHN R. FREEMAN, JR. *Metal Industry*, N. Y., Vol. 29, June 1931, pages 254–255.

Paper read before Institute of Metals Division, N. Y., Feb. 1931. A description is given of the die pressing of brass and copper alloys, mention being made of die design, tolerances and alloy compositions. See *Metals & Alloys*, Vol. 2, Mar. 1931, page 72. PRK(12h)

Stamping Equipment Employed in Radio Manufacturing. W. T. FULTON. *Metal Stampings*, Vol. 4, Jan. 1931, pages 65–67.

Describes modern metal forming equipment found in Rochester, N. Y., plant of the Stromberg Carlson Telephone Manufacturing Co. Two inverted presses of special design blank and form 400 small steel pieces per minute. An automatic spring machine forms 34,000 small flat springs per hour. Large presses are used in progressive straight line production to form loud speaker frames and radio chassis bases. Relay cases are formed from sheet aluminum in three draws. An automatic screw machine division and an up-to-date heat treating division are included in the plant. JN(12h)

The Construction and Uses of Typical Dies. Part 1. EDWARD HELLER. *Metal Stampings*, Vol. 4, Jan. 1931, pages 19–23.

Describes and illustrates design and construction of two types of cut-off and three types of blanking dies used in metal stamping with explanations of the operation, applications and particular features of each type. JN(12h)

Lubrication in Forming Decorated Sheet Metal. F. J. GAVIN. *Metal Stampings*, Vol. 4, Jan. 1931, pages 59–60.

Discusses proper selection and application of lubricants to fabrication of previously decorated flat sheet and applies principles to forming of food closure caps. To choose the best lubricant for a particular requirement, Gavin suggests: (1) investigation of all types of lubricants, (2) trial of trade marked brands, (3) research by a competent chemist, and (4) consultation with technical staffs of lubricant suppliers. JN(12h)

Wire Manufacturing and Lead Patenting. C. B. PHILLIPS. *Wire & Wire Products*, Vol. 6, June 1931, pages 226–227, 248; *Iron Age*, Vol. 127, June 25, 1931, pages 2042–2044.

Description of the manufacturing process of wires from 0.014 to 0.148 in. in diameter in the plants of the Union Wire Rope Co., Kansas City, Mo. Chilled cast iron dies are used and annealing (air patenting) at 1650° to 1700° F. is applied. Ha(12h)

Influence of the Rounding of the Punch in Deep-Drawing Hollow Bodies from Thin Sheets. (Einfluss der Abrundung beim Ziehen von Hohlkörpern aus dünnen Blechen.) H. DRAEGER (Tech. Hochschule, Dresden). *Berichte über Betriebswissenschaftliche Arbeiten* (V. D. I. Verlag-Berlin), Vol. 2, 1929, pages 1–19, 48 figures, 9 references.

Besides the properties of the metal sheet used, the product of a deep-drawing process is affected by the radius of curvature of the punch and the die, and by the play allowed between punch and die in relation to the thickness of the sheet used. Disks were stamped from soft brass sheet of 0.30, 0.35 and 0.40 mm. thick and from medium hard steel sheet of 0.25, 0.28, 0.32, and 0.42 mm. thick. The disks ran from 60 to 110 mm. diameter, and were drawn down into cups in a 50 mm. diameter die with a 49.1 mm. diameter punch. The lips of the punch and die were given different radii of curvature. The pressure on the punch was measured and automatically recorded. For the materials and thicknesses tested, a radius of 3 mm. gave best results. The effect of the radius on the diameter and uniformity of diameter of the cups was studied. Over 1000 tests are plotted in the diagrams. Draeger states that a formula previously given by Ruhrmann for determination of the proper radius leads to erroneous conclusions. He also comments especially on the lack of adequate methods for evaluation of the suitability of sheet for deep drawing. HWG(12h)

Energy Consumption and Properties of Material in Drawing of Steel Wire with Increased Drawing Velocity. (Kraftverbrauch und Werkstoffeigenschaften beim Ziehen von Stahldraht mit erhöhter Ziehgeschwindigkeit.) A. POMP. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Apr. 18, 1931, pages 498–499.

In order to determine the relation between increased drawing velocity and drawing pull and mechanical properties of the drawn wire, 3 different kinds of steel were tested at speeds from 2.3 to 7.5 m./sec. The results show a reduction of power consumption up to 5% which was accompanied by corresponding improvement of the form-changing efficiency. The respective curves are straight lines if plotted on logarithmic paper. A formula for the energy consumption of 1 mm.^{2} reduction in section could be developed. The introduction of the wire into the drawing die at higher speeds was more difficult; especially reliable safety arrangements have to be made for the protection of the workmen. Ha(12h)

Pickling (12i)

Mechanical Pickling. J. C. WEAVER. *Metal Progress*, Vol. 20, July 1931, pages 64–67.

Mass production in pickling is described. WLC(12i)

Pickling—A Cleaning-Room Process. G. H. COOPER. *Foundry Trade Journal*, Vol. 44, June 11, 1931, page 398.

Deals with the various materials used for pickling and discusses briefly the different types of equipment that can be used in the construction of pickling tanks. OWE(12i)

The Pickling of Pipe Using Commercial Inhibitors. E. L. CHAPPELL & PAUL C. ELY (National Tube Company). *Industrial & Engineering Chemistry*, Vol. 22, Nov. 1930, pages 1201–1203.

Presented at the Cincinnati meeting of the American Chemical Society, Division of Industrial & Engineering Chemistry, Sept. 1930. 2 references. Conclusion: (1) The amount of pickling acid used in dissolving scale is approximately a constant, depending only upon the weight of scale on the pipe. (2) The amount of acid used in dissolving steel is a variable which can be controlled by an inhibitor. (3) A small amount of acid is wasted in spent pickle. (4) The practical efficiency of a commercial inhibitor may be estimated from a simple hydrogen evolution test. MEH(12i)

Solution of Scale in Pickling Steel. E. L. CHAPPELL & PAUL C. ELY (National Tube Company, Pittsburgh, Pa.) *Industrial & Engineering Chemistry*, Vol. 22, Nov. 1930, pages 1200–1201.

In pickling welded pipe 95% or more of the scale is dissolved. The undissolved scale is largely silicates. The rate of scale solution is about equal to the rate of metal solution in the absence of an inhibitor. The rate of scale solution is about the same with or without an inhibitor. Scale on pipe is more quickly and completely dissolved than scale in acid without metal. MEH(12i)

Pickling, A Modern Cleaning Method. J. C. WEAVER (Weaver Brothers Co.). *Metal Progress*, Vol. 18, Dec. 1930, pages 45–49.

The author enumerates several methods of scale removal and shows pickling to have advantages of lower cost of equipment, operation and that it is sure and efficient. Older and modern methods compared. Advances in control of the chemical action by means of inhibitors are described. WLC(12i)

Notes on Construction of Pickling Tanks. J. C. WEAVER (Weaver Brothers Co.). *Metal Progress*, Vol. 19, Mar. 1931, pages 77–80, 149.

Types of destructive action in pickling tanks are analyzed and suggested materials and 3 applications are discussed. WLC(12i)

Layout for Batch Pickling. J. C. WEAVER (Weaver Brothers Co.). *Metal Progress*, Vol. 19, Jan. 1931, pages 77–80.

Equipment and methods of batch pickling are described. WLC(12i)

Cold Working (12j)

The Compressing of Surfaces. (Das Drücken der Oberfläche.) HILMAR DOERING. *Oberflächentechnik*, Vol. 8, May 19, 1931, pages 107–108; June 2, 1931, pages 117–118.

By means of a finishing method called "compressing of surfaces," tests have shown that a strengthening of the material by about 15% can be obtained. See *Metals & Alloys*, Vol. 2, July 1931, page 136. Ha(12j)

Cold Heading-Die Life. A. S. JAMESON (International Harvester Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 313–350.

Paper presented before the 12th Annual Convention of the Society, Chicago, Sept. 1930. Includes discussion, 18 references to the literature and illustrated by 28 micrographs and charts. The maximum production depends upon the die steel, die design, die heat treatment, bolt material, and machine operation. Depth of hardness, structural normality, composition and surface hardness are discussed with relation to temperature of quench and production. The critical points are considered and quenched fractures illustrated. The decisive factor is the depth of hardness. See also *Metals & Alloys*, Vol. 2, Mar. 1931, page 73. WLC(12j)

Cold Rolling of Strip Steel and Its Development. STEPHEN BADLAM. *Iron Age*, Vol. 126, Dec. 18, 1930, pages 1842–1846; *Steel*, Vol. 87, Oct. 30, 1930, pages 61–63; Nov. 6, 1930, page 56; *Engineering*, Vol. 130, Dec. 12, 1930, page 759.

Abstract of paper read before American Iron & Steel Institute. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 44. VSP+MS+LFM(12j)

Installation of Tubes. (Das Einwalzen von Rohren.) RIES. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Feb. 1931, page 44.

Review of article by Siebel in Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung, Düsseldorf, Vol. 11, leaflet 8, 1929. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 385. MB(12j)

Cleaning (12k)

Correct Cleaning Practice before Electroplating. W. L. PINNER. *Houghton's Black & White*, Vol. 4, July 1931, pages 26–29.

A few solutions for cleaning the articles to be electroplated are described. Most methods use emulsification or saponification of the oils or fats which have been used in buffing and polishing. Ha(12k)

Recent Methods for the Cleaning of Greasy Metal Parts in Industrial Operations. (Neuere Verfahren zur Reinigung fettiger Metallteile in industriellen und gewerblichen Betrieben.) H. STADTLINGER. *Oberflächentechnik*, Vol. 7, Sept. 2, 1930, pages 164–166.

Physical and chemical methods are used to free metals of fat and grease. Burning, brushing, and boiling in steam belong to the first class. The chemical method uses certain solvents, such as petroleum, benzol, etc., or alkali degreasing agents which are not inflammable. A table is given showing the times required for removing of grease by boiling in different solvents. Ha(12k)

The Advantages of Electric Metal Cleaning. D. E. WILLARD. *Houghton's Black & White*, Vol. 3, Apr. 1931, pages 22–25.

The advantages of using electric current in the cleaning bath are said to be time saved in the cleaning operation, dislodging of caked-on deposits by mechanical action, diminishing of tarnish on non-ferrous metals, possibility of lower concentrations of cleaning solutions, occasional removal of carbon smut from steel. Electric cleaning and copper or zinc plating may be done with one solution. Tank construction and solutions are discussed and the electrical part described. Ha(12k)

Cleaning House Operation. J. T. LEWIS, JR. *Wire & Wire Products*, Vol. 6, June 1931, pages 230–231, 247.

The practical layout of a materials cleaning plant is described. Here, a straight line handling of material afforded a great saving to the manufacturer of nuts and bolts. Ha(12k)

Metal Cleaning Practice in Railroad Shops. C. H. McGirr & D. E. Willard. *Houghton's Black & White*, Vol. 3, Jan. 1931, page 26.

The design of efficient cleaning tanks, care and make-up of cleaning solutions are discussed. The factors which bring about rapid production and clean work are considered. Ha(12k)

Lead Film Protects Metal under Scale. E. T. Youd (Bullard Co.). *Metal Progress*, Vol. 19, May 1931, pages 56–59.

The author describes an electrolytic cleaning method with the work as cathode and lead anodes in a sulphate-chloride bath at 150–170° F. A slight film of lead is deposited as the scale is removed which protects the metal from hydrogen embrittlement and action of the bath. This lead film does not build up. WLC(12k)

Modern Metal Cleaning. *Brass World*, Vol. 27, Apr. 1931, pages 87–89.

Discusses modern cleaning technique of British electroplaters. The heating of the cleaning tanks, rinsing, types of cleaners, detergent materials, soap solutions and conclusions to be drawn are outlined. Scouring and mopping with subsequent acid dips are liable to remain in the cases of small installations, where large quantities of material are available. A study of grease and dirt picked up in the course of fabrication makes it possible to devise a cleaning solution best suited for the particular type of oily dirt. WHB(12k)

Polishing & Grinding (12l)

Setting Up Polishing Wheels. Carl F. Weber. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, pages 687–688.

Discusses advantages of having one man in charge of setting up all polishing wheels. Wasted time of operators is eliminated, the wheels last longer, operators' production is increased, and a better grade of work results. MS(12l)

Polishing Hard Carbides on the Diamond Lathe. W. A. Wissler (Union Carbide and Carbon Research Labs.). *Metal Progress*, Vol. 19, Apr. 1931, pages 49–52.

The author describes interesting experiences with the diamond grinding trade in reaching a satisfactory polishing method for the preparation of microsections of tungsten carbide. WLC(12l)

Specifying Close Limits is Futile Without Suitable Finish. R. E. W. Harrison. *Machine Design*, Vol. 3, Feb. 1931, pages 46–48.

In order to get an objective comparison of the quality of a finished surface, an electro-magnetic type sound detector was used in connection with a loud speaker. Photomicrographs and the sound measurements made it possible to set up a scale for the quality of finish on which a cost diagram could be developed. The proper use of finish can eliminate the often very unsatisfactorily high initial wear. Ha(12l)

Use, Care and Protection of Grinding Wheels. Walter B. Leonard (American Emery Wheel Works). *Metal Cleaning & Finishing*, Vol. 2, July 1930, page 579–582.

Conditions affecting the use of abrasive wheels are the speed of wheel and work, size and shape of pieces ground, composition and temper of metal, method of grinding, condition of machine, rigidity of foundation, wet or dry grinding, quality of finish desired, etc. Discusses the factors influencing the selection of grinding wheels, economies practiced through the use of certain types, correct operating procedure, and the precautions to be observed in the protection of grinding wheels. Among the most important factors in the selection of wheels are the amount of material to be removed and finish desired. For removing a large amount of material, coarser wheels should be used. For a smooth finish, a fine wheel should be used. Soft, free cutting wheels are the most economical. MS(12l)

Coloring (12m)

Colors in Aluminum by Plating, Dyeing, Oxidizing. J. D. Edwards. *Product Engineering*, Vol. 2, Mar. 1931, pages 107–109.

By plating aluminum with Ni, Cr, Au, Ag, Cu, Zn or brass, it is possible to obtain almost any metallic finish on it possible on other materials. By oxide coating, the impurities give a gray to black color. This is made use of in aluminum shingles. Oxide coating is produced by either chemical or electro-chemical action and makes a superior foundation for protective paints. Also, by immersing the electrolytically oxidized aluminum in a hot solution of a dye, the color is readily absorbed by the oxide. If alloys of aluminum are oxidized electrolytically, the alloying constituents have a decided coloring effect. In general, a wide variety of color, texture, luster, hardness and protective qualities can be made. Ha(12m)

Finishing of Gold Filled Articles. Andrew V. Re. *Metal Cleaning & Finishing*, Vol. 2, Aug. 1930, page 683.

To oxidize Au filled or plated particles, the Au should be removed first. They are then color buffed to a very high luster. The parts are placed for 5–8 min. in a good grade of metal cleaner held at the boiling-point. Oxidizing solution consists of 5 oz. $CuCO_3$ and 1 pt. NH_4OH, and is operated at 150–170° F. The parts are rinsed well in cold and hot H_2O, color buffed if necessary, and lacquered. MS(12m)

Oxidized Copper, Brass and Silver Finishes on Aluminum and Its Alloys. R. E. Pettit. *Monthly Review American Electroplaters' Society*, Vol. 17, Dec. 1930, pages 9–13.

The coloring or oxidizing of plated aluminum can be made just as well as in the case of other metals and depends on the skill of the operator and the methods used. For general use, preliminary nickel plating is recommended. The aluminum or its alloy is first cleaned for about 30 sec. in a hot mild alkaline cleaner such as 1 to 3 oz./gal. each of trisodium phosphate and sodium carbonate. This followed by a clean cold water rinse. A treatment with hydrofluoric acid or 3 parts nitric and 1 part hydrofluoric acid, depending upon the kind of material, follows at room temperature. After further rinsing, it is ready for nickel plating. This treatment changes somewhat according to the kind of material: cast, pure aluminum, or kind of alloy. The respective pretreatments are described. Copper, brass or silver may readily be plated over the nickel and these coatings oxidized to give the various colored effects by well known processes. Ha(12m)

The Coloring of Tin, Tin Lead, and Aluminum Foils. W. W. Rogers. *Metal Industry*, N. Y., Vol. 29, Aug. 1931, pages 341–343.

A detailed description is given of dye solutions and the method of applying them. PRK(12m)

Sand Blasting (12n)

A New Design of Sand-Blast Room. *Foundry Trade Journal*, Vol. 44, June 4, 1931, page 386.

A new design of Gutmann plant is described, in which a turntable is used, half of the table being inside and half outside the room. In this way, while the operator is sand-blasting work on the half inside the room, another man can remove the clean castings and substitute others for blasting. OWE(12n)

DEFECTS (13)

On the Origin of Flakes in Steel. C. Benedicks & H. Löfquist. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 115–124; 2 figures, 23 references; *Jernkontorets Annaler*, No. 11, 1929, pages 592–600.

Flakes are ascribed to lack of cohesion between dendrites, aggravated by sudden temperature changes and lack of equalization of temperature. Low casting temperature, prompt transference to soaking pits, forging without cooling below forging temperatures and cautious cooling after forging, are advised. HWG(13)

On Impurities in Metals. Francis Bitter. *Physical Review*, Vol. 37, June 1, 1931, pages 1527–1547.

In order to arrive at a satisfactory understanding of many of the properties of metals, especially ferromagnetic metals, it is necessary to take into account the distorting effect of impurities and of other irregularities in the crystal lattice. The present paper is an attempt to describe some of the corrections that must be applied to the usual model of a perfect crystal before it can be expected to reproduce the properties of actual substances. Starting with the usual law of force between any two atoms—repulsion for small distances, attraction for large distances—the distortion of the lattice in the immediate neighborhood of an atom of impurity is discussed, with especial reference to the significance of the formation of molecules. Phase distributions in substances capable of allotropy are described, together with the influence of impurities on such distributions. The existence of diffusion makes it possible to apply statistical mechanics to solid solutions. It is shown that, in general, atoms of impurities in solids do not exert long range forces on each other by means of the distortions they produce in the lattice. This makes it possible to give simple formulae for the distribution of concentration of the impurities. These distributions are sometimes far from uniform, and a phenomenon similar to opalescence in gases may occur. Applications of the above concepts to ferromagnetic solutions are pointed out, and it is suggested that the ferromagnetism of austenite containing in the neighborhood of 0.8% C. may be due to the presence of small granules of α-iron resulting from local fluctuations in the distribution of carbon atoms. WAT(13)

Brittleness in Copper. Clement Blazey. *Institute of Metals, Advance Copy* No. 563, Oct. 1931, 29 pages.

Work previously published indicated that a peculiar type of brittleness infrequently occurred in annealed arsenical copper. The present work shows that such brittleness is not confined to As-Cu, but can be produced in As-free Cu. The necessary conditions for production of brittleness appear to be a low oxygen content and the presence of a small amount of Bi. Brittleness can be developed by cold working followed by one of the following anneals: (1) below a certain critical temperature, which is usually about 650° C., (2) by slowly cooling from above this temperature, and (3) by quenching from above the critical temperature and reheating to slightly below it. When the Cu is quenched from an annealing temperature above the critical it is free from brittleness. The ease with which brittleness could be produced increased with decreasing O content. 5 references. JLG(13)

Causes of Failures of Sheet and Tin Sheet Rolls. (Brüche an Fein- und Weisblechwalzen und ihre Ursachen.) H. Fey. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, pages 391–392.

H. Fey summarizes an article on the above subject by J. S. Caswell in *Proceedings South Wales Institute of Engineers*, Vol. 46, 1930, No. 4, pages 311–452. (Sheet and Tinplate Rolls. *Metals & Alloys*, Vol. 2, Jan. 1931, page 11.) The article deals with the following subjects: Manufacturing of rolls, statistical research of failures of rolls, observations on temperature fluctuations of the rolls, rolling pressure during the rolling of plates and tin sheets, stresses due to the deformation work of rolling, torsion stresses, physical properties and investigations of the structure of plain cast iron rolls and chilled cast iron rolls, values and changes of value of the stresses during rolling, hair cracks and burned spots of the fractures. GN(13)

Research on Wrought-Iron Chains. The Nature of Defective Laminations in Wrought-Iron Bars and Chain Links. H. J. Gough & A. J. Murphy. *Iron & Steel Institute, Advance Copy* No. 8, May 1931, 19 pages.

The fractured surface of wrought iron sometimes reveals a lamination having a brittle, crystalline appearance. The layers have sometimes been referred to as "burnt." A 1 in. diameter bar of "Genuine Treble Best Wrought Iron" was found to have a defective layer and this layer was exhaustively studied. Analysis of the defective layer indicated 0.48% P and 0.38% Si. A thermal study indicated no transformation on heating or cooling. It was concluded that the combined P and Si content was great enough to suppress the α-γ transformation, and that the type of defect studied was caused by the inclusion of an imperfectly refined bar in the "pile." Grain refinement of such material does not result from heating. Mechanical tests proved that the defective layer was harder than normal iron, and less resistant to shock. The presence of such a layer can be detected by nicking and breaking a bar. Contains 9 references. JLG(13)

Ghosts in Large Steel Forgings. J. Fletcher Harper & Harold J. Stein. *Metal Progress*, Vol. 20, July 1931, pages 45–49.

A portion of a paper to be presented before the Boston Convention of American Society for Steel Treating, Sept. 1931, and to be published in greater detail with discussion in the Transactions. Brief literature study of "ghosts" is given and the properties of forgings containing such defects are discussed. Methods of detection illustrated by photographs and micrographs are given. WLC(13)

Identifying Causes of Boiler-Metal Cracking. F. G. Straub. *Power*, Vol. 73, May 26, 1931, pages 809–812.

The "embrittlement" of boiler material is discussed. In almost all cases where boilers have become embrittled they have been found to be free from scale and any indications of corrosion. The boiler water enters the small capillary crevices in the seams. Under the conditions of fluctuating temperatures and pressures in the boiler, the water in these spaces slowly concentrates until a high concentration results. This concentration takes place in the areas adjacent to the rivets, where the metal is usually highly stressed. The caustic attacks the highly stressed metal by penetrating between the grain boundaries. If the sulphate content of the water is high enough its precipitation will cause a protective formation over the metal and no cracking will occur. A number of micrographs and photographs are shown illustrating characteristic failures. WAT(13)

On the Embrittlement of Wrought-Iron Chain by Stress and the Superiority of Cast-Steel Chain. H. Kikkawa. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, Part 2, pages 195–198.

Wrought iron becomes brittle when overstrained, its impact value falling, sometimes to a third of the original value. Heat-treated 0.25% C, 0.7 or 1.5% Mn is preferred, because of higher breaking load, higher impact tensile strength, lower cost in sizes above 2" diameter of chain, and better low temperature impact resistance, as shown below.

	Izod ft.-lbs. at 22° C.	Izod ft.-lbs. at −21° C.
Cast Steel of 0.24% C, 0.35% Si, 0.55% Mn	52	43
Wrought Iron of 0.01% C, 0.10% Si, 0.08% Mn	14	6

The heat treatment of the cast steel is not stated. HWG(13)

The Ingot Phase in the Manufacture of Rolled Steel Products. Part VII. JOHN H. HRUSKA. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 55–56, 60.

Gives chemical analyses and microphotographs of inclusions found in various kinds of steel ingots. Suggests better pouring and teeming practice to eliminate scale-like surface inclusions. Slag-like inclusions found below surface show insufficient time allowed for "settling" of steel between tapping and teeming. Wide-spread defect of "abnormality" in steel due to presence of microscopic inclusions of oxidation products of slag materials. These inclusions best demonstrated by presence of "ghost-lines" in microscopic sections. Ghost-lines contain phosphorus, sulphur and some silicon, with the carbon content about the same as the rest of the specimen. JN(13)

A New Type of Inclusion in Cast Iron and its Relation to Manganese and Silicon Content. F. J. COOK. *Foundry Trade Journal*, Vol. 44, May 14, 1931, pages 335–336, 345.

It was found that inclusions of a bright glazy nature in cast iron caused H_2O to sweat through glazed areas when subjected to steam pressure. See *Metals & Alloys*, Vol. 2, July 1931, page 136. VSP(13)

Season Cracking of Brass. (Das Aufreissen von Messing.) F. OSTERMANN. *Metallwirtschaft*, Vol. 10, Apr. 24, 1931, pages 329–337.

Contains 13 references. It is well known that brass in the form of tubes, rod or sheet sometimes suddenly bursts apart after a short period of storage. This only occurs in cold worked brass and is due to heterogeneous internal strains. These are not the same as the homogeneous work-hardening strains and are not proportional to the hardness. They are of macroscopic size and cause a weakening rather than strengthening of the metal. Usually these internal strains can be removed by annealing at low temperatures, at which the hardness is not affected. Bursting of strained brass is caused by the corrosion of ammonia and ammonium salts which are present in air in small quantities. This occurs along the grain boundaries and causes intercrystalline fracture. Brass actually has an affinity for ammoniacal gases. Acids attack brass uniformly, not along grain boundaries, and do not cause bursting. An accelerated test for bursting tendency is to dip the brass in a 1% $HgNO_3$, 1% HNO_3 solution for several minutes. Hg forms a weak, brittle alloy along the grain boundaries, which causes bursting if the metal is internally strained. The Hg test cannot be used to compare brasses of different composition or surface condition as these factors influence the rate of Hg and atmospheric attack in different proportions. Pure α brass with 63% Cu corrodes faster than $\alpha + \beta$ brass with 61–62% Cu. Corrosive attack will cause bursting only if the surface of the metal is under tensile stress and the interior of the metal is under compressive stress. The manner by which the internal strains are set up during rolling and cold working of bars, sheets and tubes are described and methods for the determination of the longitudinal and tangential stresses are given. In tubes the strains increase (1) with increasing wall thickness, (2) with greater reduction of the diameter and (3) by hollow drawing, in contrast to drawing over a fixed mandrel. When brass sheet is bent the strain is proportional to the angle of bending and the reduction during rolling. In brass containing 60% Cu the strains are very high, with 63–70% Cu they are less and with 85–90% Cu very low. Fe up to 0.15% and Pb up to 1.26% increase the strains slightly, Sn up to 1% decreases them slightly. The tendency of sheets and rods to burst is not directly proportional to amount of cold reduction, but is highest with 20–22% reduction, then decreases again. The only way to prevent bursting of strained brass is by removal of the strains by annealing. The temperature depends on the Cu content, time and amount of internal strain. For 60/40 brass 200°–250° C. is sufficient, for 70/30 250°–300°. For very hard brass it is difficult to keep the annealing temperature below the softening temperature. The internal strains can be reduced to a minimum by properly selecting and closely controlling manufacturing processes. The tendency to burst is reduced by storing in dry places. CEM(13)

CHEMICAL ANALYSIS (14)

Effect of Illium Crucibles on Volatile Determinations in Coal. J. A. ADDLESTONE. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, page 422.

Data are shown which indicate that the volatile-matter determination as made in illium crucibles gives results consistently lower than those obtained by the standard method with the use of platinum crucibles. MEH(14)

Determination of Titanium in Alloy Steels. (Bestimmung des Titans in legierten Stählen.) J. AREND & H. SCHELLENBACH. *Archiv für Eisenhüttenwesen*, Vol. 4, Nov. 1930, pages 265–267; *Stahl und Eisen*, Nov. 27, 1930, pages 1681–1682.

The authors developed 2 new methods for the determination of Ti in alloy steels either of which can be easily made with sufficient accuracy. Both methods, a gravimetric one and a colorimetric one, are described in detail. The colorimetric method gives correct results (deviation, 0.005%) for Ti contents up to 0.5%. The values obtained with both methods are in accordance. GN(14)

The Determination of Silver in Steel. (Silberbestimmung in Stählen.) WALTER BERG. *Chemiker-Zeitung*, Vol. 55, Apr. 4, 1931, page 259.

A 10–15 gm. sample is dissolved in 1:1 HCl and evaporated to dryness, taken up in 1:1 HCl and filtered. The precipitate on the filter is dissolved in NH_4OH, filtered and reprecipitated with HCl and saved. H_2S is passed through the first filtrate, the precipitate filtered, dissolved in aqua regia, evaporated to dryness and redissolved in HCl. The solution is made alkaline with NH_4OH and Fe is filtered off. It is then made weakly acid with HCl and combined with the other HCl solution. AgCl is filtered off and determined in the usual manner. CEM(14)

Application of the Spectrograph to the Analysis of Non-Ferrous Metals and Alloys. H. W. BROWNSDON & E. H. S. VAN SOMEREN. *Institute of Metals, Advance Copy* No. 564, Oct. 1931, 17 pages.

Part I discusses the field and advantages of spectroscopic analysis as applied to metals and alloys. Part II gives detailed directions for the quantitative spectroscopic determination of various elements in brass. The method for estimating the quantities present consists in a comparison of the intensity of certain lines of the element in consideration with the intensity of certain Cu lines. Tables that make this possible are given for Pb, Sn, Fe, Ni, Al and Mn. They are for use with arc spectra. Part III contains similar data for Pb. Spark spectra are recommended. The tables are for Sn, Sb, Cd, As, Bi, Cu, Zn and Ag in Pb. Th and Hg lines have also been found in commercial Pb, and the intensities of such lines for a given amount of these elements are given. JLG(14)

Apparatus for the Commercial Determination of the Total Zinc Coating on Steel. (Apparatur zur betriebsmässigen Bestimmung der gesamten Zinkauflage auf Stahl.) GOEKE. *Chemische Fabrik*, Vol. 4, Apr. 1, 1931, pages 147–148.

The weighed sample in the form of wire or sheet is introduced into a 100 cc. glass stoppered bottle, which is connected with a 100 cc. burette. A measured amount of a normal HCl + 3% $SbCl_3$ solution is added and the acid displaced by the liberated H_2 is measured in the burette. From this the weight of zinc is calculated. The method is quick, simple and accurate. CEM(14)

Determination of Magnesium with 8-Hydroxyquinoline—Gravimetrically, Volumetrically and Colorimetrically. W. A. HOUGH & J. B. FICKLEN *Journal American Chemical Society*, Vol. 52, Dec. 1930, pages 4752–4755.

Quick determinations of magnesium can be made by precipitating it as the salt of 8-hydroxyquinoline and estimating the magnesium content of the salt either gravimetrically, etc. In many cases where the saving of time is an important factor and extreme accuracy is secondary, one of these methods may prove useful. None of the other metals commonly found in natural waters will react with the reagent except calcium. MEH(14)

The Titration of Free Cyanide in Copper Baths. M. R. THOMPSON. *Monthly Review American Electroplaters' Society*, Vol. 18, May 1931, pages 31–37.

Describes a method of titration with potassium iodide. Ha(14)

The Spectrographic Assay of Some Alloys of Lead. D. M. SMITH. *Institute of Metals, Advance Copy* No. 581, Oct. 1931, 15 pages.

The possibility of applying spectrographic methods to the routine analysis of Pb alloys containing Cd, Sb and Sn was investigated. The method was found to be quite satisfactory for estimating quantities less than 1%. The spark method is the more accurate. Analyses were made both by comparing the intensities of certain lines in the element to be determined with Pb lines and by the logorithmic sector method. 5 references. JLG(14)

Analytical Standards in the Laboratory. F. J. WATSON & R. E. SUMMERS, *Chemical Engineering & Mining Review*, Vol. 23, June 5, 1931, pages 349–354.

A portion of the opening address at a discussion of the subject held by the Analytical Group of the Australian Chemical Institute (Victorian Branch) Apr. 15, 1931. A discussion including the standardization of volumetric glassware, analytical standards and working standards. The standards authorized throughout the I.C.I. are: (1) ultimate standard—pure Ag, (2) working standards—iodine, sodium sesquicarbonate, NaCl, (3) secondary working standards—sodium oxalate, and arsenic trioxide. A diagrammatic scheme shows the standardization system based on pure Ag. WHB(14)

Determination of Zinc with Pyridine and Ammonium Thiocyanate. C. FRANKLIN MILLER. *Chemist-Analyst*, Vol. 20, May 1931, pages 8–10.

This method is particularly suitable for the analysis of zinc salts and is quicker and more accurate than the phosphate method. To a neutral solution containing about 0.3 g. Zn in 500 cc., 4 g. of NH_4SCN and 2 g. pyridine dissolved in a small amount of water are added. The precipitate is filtered on a Gooch crucible and washed with (1) 3 g. NH_4SCN + 5 cc. pyridine/liter, (2) 13 cc. 95% alcohol + 85 cc. H_2O + 1.5 cc. pyridine + 0.1 g. NH_4SCN, (3) 10 cc. absolute alcohol + 1 cc. pyridine, (4) 15 cc. ether + 2 drops pyridine. The precipitate is dried at 65–70° and weighed. It contains 19.25% Zn. CEM(14)

Investigations on Helium. VIII. Quantitative Determination of Very Small Amounts of Helium. (Heliumuntersuchungen. VIII. Ueber eine Methode zur quantitativen Bestimmung kleinster Heliummengen.) F. Method for determining quantities of He between 10^{-4} to 10^{-8} cm.^{3} in metals. EF(14)

Identification of Aluminum and Magnesium in Printing Inks. LOUIS M. LARSEN. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, pages 416–417.

Three references. The identification of both Al and Mg involves the use of lake-forming dyestuffs, capable of detecting small quantities of the above elements in the presence of other ingredients in inks (and pigments). These dyestuffs are aluminum for Al and benzopurpurine 4B for Mg. Procedures are given. MEH(14)

Titration of Lead by Means of a Thermionic Titrometer. R. W. GELBACH & K. G. COMPTON. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 2, Oct. 15, 1930, pages 397–398.

Two circuits, one a three-tube, and the other a two-tube titrometer, are described and shown by diagram, for determining the equivalence point in the titration of lead nitrate with potassium chromate. No curves are required. MEH(14)

Modified Gravimetric Determination of Manganese. FREDERICK G. GERMUTH. *Chemist-Analyst*, Vol. 20, May 1931, page 11.

In precipitating $MnO(OH)_2$ from H_2SO_4 solutions the use of fuming H_2SO_4 and $K_2S_2O_8$ instead of $(NH_4)_2S_2O_8$ is recommended. The precipitate coagulates readily and is easy to filter. Ignition at 1000° C. converts it to Mn_3O_4. CEM(14)

Germanium in Meteors of Cranbourne. (Ueber das Vorkommen des Germaniums in Meteoriten von Cranbourne.) V. M. GOLDSCHMIDT (University of Göttingen) *Zeitschrift für physikalische Chemie*, Sect. A Vol. 146, Mar. 1930, pages 404–405.

Chemical and X-ray spectrographic analysis yielded 0.1% of this rare element besides traces of Cu, Zn, Ga, As, Pb, Sn, Mo, Ru, Pt, Ir, Pa, Rh, Ag, Os and Au. EF(14)

A Modification of Penny's Method for Determining Iron in Iron Ores. ROY P. HUDSON. *Chemist-Analyst*. Vol. 20, May 1931, pages 6–7.

The bichromate titration with an internal indicator has several advantages over the permanganate method. 0.5 g. of ore is dissolved in 10 cc. HCl and reduced with $SnCl_2$. After heating to complete solution, $KMnO_4$ is added, then $SnCl_2$ to complete reduction and 1 cc. excess. The solution is cooled and diluted and 8–10 drops 1% diphenylamine solution added. Then 1 cc. $HgCl_2$ and 20 cc. H_2SO_4 – H_3PO_4 are added and the solution titrated until the green color changes to deep blue. CEM(14)

HISTORICAL & BIOGRAPHICAL (15)

Ups and Downs of Titanium. G. F. COMSTOCK. *Metal Progress*, Vol. 19, Apr. 1931, pages 58–63.

The history of titanium recovery is outlined. The use of titanium as a deoxidizer is described particularly with reference to metal for rails. WLC(15)

The True Story of Wrought Iron. J. A. COMSTOCK. *Industrial Record*, Mar. 1931, pages 23–24, 56, 60.

A non-technical history concluding with practical hints. MFB(15)

An Egyptian Axe-Head of Date 1800 B.C.: Its Investigation and Reproduction. H. C. H. CARPENTER. *Nature*, Vol. 127, Apr. 18, 1931, pages 589–591.

Investigation showed, by etching with $(NH_4)_2S_2O_8$, a dendritic structure composed of an alloy of high Cu content. Dendritic structure also showed that the axe was cast. Brinell hardness showed 90 on flat to 112 at the edge. Chemical analysis gave 96.9% Cu, 1.5% As, 0.7% Fe and 0.2% Sn. The remaining 0.7% was Ni, S and O. The axe-head was reproduced, using an alloy of the same shape and composition and was subjected to mechanical and thermal treatments which microscopic and hardness treatment showed in the Egyptian axe-head. Investigation showed that hardening by cold work is permanent in this type of alloy. VSP(15)

Pioneering at Midvale. JOHN L. COX & F. B. FOLEY (Midvale Co.). *Metal Progress*, Vol. 18, Nov. 1930, pages 51–55.

The authors sketch historically the developments in the metallurgical art made at Midvale. The open hearth, pyrometry, high speed tool steel, and automotive and ordnance alloy steels are among the subjects of Midvale's pioneering. WLC(15)

Nickel—Its History, Refining and Uses. H. W. WALTER. *Canadian Chemistry & Metallurgy*, Vol. 15, July 1931, pages 185–191.

A paper presented at the Canadian Chemical Convention, Montreal, May 27–29, 1931. Sources of Ni, smelting operations at Copper Cliff, refining from Bessemer matte, the Mond and the Hybinette processes are discussed. Charts show the flowsheet of operations at the Port Colborne refinery and the flowsheet showing the flow and purification of electrolyte. Uses are also discussed. WHB(15)

Development and Progress of Rolling Mill Practice in Japan. G. NAGATA. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, pages 639–666.

In English. Description of Japanese Mills. HWG(15)

A Unique Iron Meteorite from Mexico. H. H. NININGER. *American Journal of Science*, Vol. 22, July 1931, pages 69–71.

While in Mexico City in November 1929, the writer was shown a meteoric fragment weighing 24 lbs. which had been presented to the Director of the National Observatory. Cut into the iron was a legend to the effect that it had come from within the city of Chihuahua. Through the courtesy of the Director a small pièce was cut off for the purpose of study and identification. Polishing and examination under a lens showed the structure to be largely dendritic schreibersite in minute granules. The distribution of these granules was of two kinds (1) they were scattered variously throughout the metal and (2) they were arranged in pairs of parallel rows, a pair of which together with an included strip of about the width of one row, measured about a millimeter across. Chemical analysis of the sawings from this meteorite was made with the following results:

Fe	91.16	Cu	0.14	S	0.07
Ni	6.96	Cr	0.02	C	0.05
Co	0.40	P	0.42	SiO_2	0.06

Historical Sketch of Minting Work in Japan. T. HIROSE. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol 36, *Mining & Metallurgy*, Part 4, pages 65–78. (In Japanese, English abstract.)

Four Japanese prints of ancient minting operations are shown. Historical, with some comment on present methods, which are said to be quite similar to those of other mints. HWG(15)

Chronology of Iron and Steel. Compiled by STEPHEN L. GOODALE. Penton Publishing Company, Cleveland, 1931. Cloth, 4 × 6½ inches, 332 pages. Price $4.15.

The first edition of this book briefly chronicled the more important events in the iron and steel industries from biblical times up to and including the year 1919. The new edition is only an extension of this information to include the first quarter of 1931.

The book is arranged chronologically, that is, the years are listed in order and under each are mentioned new processes, new equipment and all other important developments that occurred in the iron and steel industry in that year. It also includes a complete index in which the events, processes, etc., are arranged alphabetically, with a reference to the years under which they may be found.—RICHARD RIMBACH(15)-B-

The Swedish Acid Bessemer Process. (Den svenska sura bessemerprocessen.) ARVID JOHANSSEN. *Jernkontorets Annaler*, Vol. 115, May 1931, pages 239–278.

The History of Impact Testing. (Historique de la découverte et du développement des applications de l'essai au choc sur barreaux entaillés pour déceler la fragilité de l'acier.) HENRY LE CHATELIER. *Revue de Métallurgie*, Vol. 28, May 1931, pages 245–253.

Considere discovered that steel might be fragile and that this fragility cannot be discovered by tensile testing (Bulletin de l'Association des Ingénieurs des Ponts et Chaussées du Sud-Ouest, Jan. 18, 1888). André Le Chatelier found in 1892 that this property can be demonstrated by using a specimen notched with a saw and subjected to an impact test. The original testing involved the number of the hammer blows required for breaking the specimens. Frémont in 1897 proposed the determination of the resiliency of the sample from the loss of the energy stored in the weight breaking it. Charpy inspired by the work of Russel suggested, in 1900, the use of a pendulum for breaking the specimen also using a notched specimen and determining the loss of energy of the pendulum. Guillery used, for breaking of the sample, a rapidly rotating fly wheel measuring the drop of speed in the moment of breakage. Izod improved on the ideas of Charpy. JDG(15)

Fifty Years of Physical Metallurgy. H. M. BOYLSTON. *Proceedings of the World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*. Part 4, pages 197–209.

See *Metals & Alloys*, Vol. 1, July 1930, page 626. HWG(15)

The Development of Electrolytic Metals in Canada. W. R. MCCLELLAND. *Canadian Mining Journal*, Vol. 52, May 8, 1931, pages 470–474.

A brief record of what has been accomplished and possibilities of further expansion. Aluminum, cadmium, lead, nickel and zinc are reviewed; and magnesium, beryllium and iron are pointed out as possibilities. WHB(16)

Tin in 1929. CHARLES WHITE MERRILL. *Mineral Resources of the United States*, 1929, Part 1, Apr. 25, 1931, *United States Bureau of Mines*, pages 333–362.

In 1929 the U. S. imported for consumption 87,127 long tons of tin (an increase of 12%) reclaimed 30,625 tons (a decline of 4%) and produced 35 tons (Alaska 34.5 tons). Tin stands tenth in value among the commodities imported for consumption in the U. S. and accounts for 2.1% of the total domestic imports. World mine production of tin in 1929 was 185,000 long tons, an increase of 4% over 1928. Federated Malay States produced 36%, Bolivia 25% and the Netherland East Indies 17%, 78% from 3 countries. Straits Settlements (1/2), United Kingdon (1/3) and Netherland East Indies (1/7) smelted over 90% of the total. AHE(16)

The Basic Bessemer Process. Some Considerations of Its Possibilities in England. VERNON HARBORD. *Iron & Steel Institute, Advance Copy* No. 9, May 1931, 17 pages.

The basic Bessemer is extensively used on the Continent, but has been almost entirely superseded by the basic open-hearth in Great Britain. The basic Bessemer requires a particular type of iron for successful operation. The ores available for producing such iron are discussed. It is concluded that the possible saving with the basic Bessemer amounts to about 7s. per ton. The Bessemer process has the advantages of lower labor cost, lower plant cost, lower fuel consumption, regular delivery of ingots in small quantities, and a higher credit for the slag. It has the disadvantages of a lower ingot yield, allowing little scrap use, of not using blast furnace or coke oven gas, and of less control of the process. Contains 2 references. JLG(16)

Gold, Silver and Copper in Wyoming in 1929. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, Apr. 20, 1931, pages 271–273.

In 1929, Wyoming metal mines produced gold worth $995 ($677 in 1928), 26 ounces of silver worth $14 (53 oz., $31 in 1928) and 4,301 pounds of copper worth $757 (2,604 lbs., $375 in 1928) for a total of $1,766 ($1,083 in 1928). AHE(16)

Gold, Silver and Lead in South Dakota in 1929. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, April 20, 1931, pages 265–270.

Gold production in South Dakota in 1929 was 316,836.85 oz., worth $6,549,599, a slight decrease from 1928; silver output was 85,182 oz., worth $45,402, a decrease of about 6 and 14%, respectively. Almost all of this production is from the Homestake mine, the largest producing gold mine in the United States and a continuous producer since 1875. AHE(16)

Copper in 1929. C. E. JULIHN & H. M. MEYER. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, June 3, 1931, pages 525–580.

In 1929 smelter output of copper from domestic ores was 2,002,863,135 lbs., refinery production of new copper was 1,982,732,298 lbs., world smelter production was 4,199,805,000 lbs., all the largest ever recorded. North America supplied 59%, South America 19%, Europe 9%, Africa 8% and Asia 4%. 5 references. AHE(16)

Gold, Silver, Copper and Lead in Oregon in 1929. V. C. HEIKES. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, May 15, 1931, pages 471–483.

The total value of the mine production of gold, silver, copper and lead in Oregon in 1929 was $486,000, an increase of 64% over 1928. There were increases in the output of all metals except silver. AHE(16)

Gold, Silver, Copper, Lead and Zinc in California in 1929. V. C. HEIKES. *Mineral Resources of the Unites States*, 1929, Part 1, *United States Bureau of Mines*, May 15, 1931, pages 431–470.

The output of gold, silver, copper and lead from California mines in 1929 was valued at $15,090,589, a decrease of 2% compared with 1928. Gold decreased 21%, silver 20% in quantity and 27% in value and lead 24% in quantity and 18% in value. Copper increased 32% in quantity and 61% in value. No zinc was reported produced. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Washington in 1929. C. N. GERRY & T. H. MILLER. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, Apr. 31, 1931, pages 413–430.

The value of the mine production of gold, silver, copper, lead and zinc in Washington in 1929 was nearly 13% less than in 1928. The large decrease in the output of gold and silver offset the decided increase in the output of copper and zinc. Lead output decreased slightly. AHE(16)

Production and Applications of Light Metals and Their Alloys in Italy. (Produzione ed applicazioni dei metalli leggeri e loro leghe in Italia.) A. W. BONARETTI. *Metalli Leggeri*, Vol. 1, Jan.-Feb. 1931, pages 7–17.

Stresses Italy's lack of iron ore and coal, which leads to the need of greater utilization of her stores of ores of the light metals and her hydro-electric power to produce metals for national defense. Italy now has capacity for production of some 15,000 tons of Al and 500 tons of Mg per year. She may have beryllium ores for use when that metal comes into commercial use. Of 8,000 tons Al produced in Italy in 1930, 20% went into electrical conductors, and 40% each into other wrought forms and into castings. The advantages of light metals and alloys for electrical conductors and for construction of all kinds of vehicles for transportation are discussed at length, with a list of several hundred applications. HWG(16)

Gold, Silver, Copper, Lead and Zinc in Idaho in 1929. C. N. GERRY & T. H. MILLER. *Mineral Resources of the United States*, 1929, Part 1, *United States Bureau of Mines*, Apr. 31, 1931, pages 363–412.

The value of the mine production of gold, silver, copper, lead and zinc in Idaho increased from $26,667,706 in 1928 to $31,104,246 in 1929. The quantity of all except gold increased materially. The output of zinc was the largest ever recorded in the state. 19 references. AHE(16)

The Italian Production of Cadmium—the Process at the Monteponi Plant. (La produzione nazionale del Cadmio. Il processo e l'impianto di Monteponi.) L. CABMI & V. TOJA. *Giornale di chemica industriale ed applicata*, Vol. 13, June 1931, pages 281–296.

World cadmium production has risen, along with the increase in electrolytic zinc, from 230 tons in 1914 to 1780 tons in 1929. In the latter year, the U. S. produced about 1125 tons. The Monteponi plant in Italy can produce 30 to 35 tons a year. The ore used contains about 21% Zn and 0.05% Cd. The Cd is thrown down from the H_2SO_4 solution as cement cadmium by zinc dust. The fine precipitate oxides rapidly, and the oxides are dissolved with H_2SO_4 plus a little HNO_3. The solution is purified with iron sulphate and with permanganate, and ferric hydrate and manganese compounds precipitated with lime, giving a solution with about 83 g. Cd, 21 g. Zn per liter. The cathodes are moved up and down at 90 strokes per minute, and the electrolyte is agitated intermittently and held at 40–45° C. The current density is 50 amps./m.², and the current efficiency 98.4%. 1.7 KWH is required for 1 kg. of Cd deposited. Very compact cathode deposits are obtained. These are stripped, melted under heavy oil and then remelted under fused NaOH. The resultant Cd runs 99.92%, containing 0.033% Zn, 0.041% Pb, 0.004 Fe, and no Cu. HWG(16)

The World's Production of Minerals and the Modern Prospecting. (La production mondiale de minerais et la prospection moderne.) CH. BERTHELOT. *Revue de Métallurgie*, Vol. 28, May 1931, pages 289–301.

After giving statistical information regarding the mineral industry of the world the author gives some data regarding cost and methods of prospecting and organizations of mining undertakings. JDG(16)

The Limits to Specifications; the Costs of Accuracy. (Grosszahlforschung und Normung.) DAEVES. *Automobiltechnische Zeitschrift*, Vol. 34, Apr. 20, 1931, page 271.

Limits and specifications on mass production products must depend upon the variable curve of the individual product if costs are to be within reason. In a specific example the curve is set up for the carbon content in steel. Maximum variable was found to be 0.1%. If the carbon content was to be kept between 0.14 and 0.16% then rejections are reduced to 11% of the product. If another 0.1% is added to either limit (0.12 and 0.18) then only 2.5% of the product need be rejected. The purchaser then must consider his limits from the standpoint of accuracy as compared with the costs of accuracy dependent upon the particular variable curve. WHB(16)

The Iron and Steel Industry of Japan. S. HATTORI. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Vol 33, published 1931, *Mining & Metallurgy*, Part 1, pages 43–78.

Historical account, with present status. Japan lacks good coking coal and her iron sands are titaniferous and give difficulty in smelting. Statistics of blast furnaces, open hearth and rolling mill capacities are given. There are some 20 electric iron furnaces of less than 500 K. W. and 43 from 500 to 3000 K. W. HWG(16)

Copper and Its Alloys. WM. CRAWFORD HIRSCH. *Electrical Manufacturing*, Vol. 8, July 1931, pages 33–34.

About 47% of the world's copper is produced in the United States. The price has dropped from 23½ cents a pound in March 1929 to 8½ cents in June 1931. The three principal grades of copper are; electrolytic, Lake Superior, and casting copper from ore and scrap. There are approximately 14 tons of electrolytic copper used to every ton of Lake copper. The consumption of casting copper, as compared to electrolytic is trifling, amounting to 5000 tons in an average year. No figures are available on the amount of copper used in its alloys. WAT(16)

The Natural Resources of the Iron and Steel Industry in Sweden. A. JOHANSSEN. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 31–42.
The pure ores of Sweden will suffice for many years. Probable future shortage of charcoal can be met by wider use of electric furnace processes. HWG(16)

The World's Iron Ore Supply. C. K. LEITH. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 1–30.
Extended discussion of the iron ore situation in all countries, from the economic, military and political points of view. HWG(16)

Effect of the Fall in Metal Prices on Base-Metal Mining. WILLIAM PELLOW-HARVEY. *Metal Industry*, London, Vol. 38, May 29, 1931, pages 551–553; June 5, 1931, pages 575–576; June 12, 1931, pages 606–607.
Condensed from Presidential Address to Institution of Mining and Metallurgy, May 21, 1931. Statistics are given of the production, prices, and values of the various common metals produced in the British Empire. PRK(16)

Cadmium. W. G. RUMBOLD. *Canadian Mining Journal*, Vol. 52, May 15, 1931, page 456.
A reprint from *Mining Magazine*. An expanding market in cadmium is met from the electrolytic zinc plants in Tasmania, Canada and the U. S. WHB(16)

Economic Aspects of Sponge Iron Production in Canada. BRADLEY STOUGHTON. *Transactions Canadian Institute of Mining & Metallurgy*, 1930, Vol. 33, pages 74–79; Discussion, pages 80–98.

Zinc in 1929. ELMER W. PEHRSON. *Mineral Resources of the United States*, 1929, Part 1, July 6, 1931, pages 675–727, *United States Bureau of Mines*.
The production of primary Zn in 1929 (625,447 short tons) was the largest since the war. Production from domestic ores increased 3.5% over 1928 and from foreign ores 20.4%. Electrolytic Zn amounted to 25% of the total primary output (26.6% in 1928). The recovery of unalloyed secondary Zn (65,400 short tons) decreased 7.5%. World smelter production (1,613,000 short tons) exceeded all previous records and was 3% more than 1928. Montana was the leading producer of metallic Zn (13% less than in 1928), Illinois second (8% increase) and Oklahoma third (5% increase). AHE(16)

PLANTS & LABORATORIES (17)

Ontario Research Foundation, Report for 1930. J. W. FLAVELLE. Published by H. W. Ball, Toronto, 1931, 31 pages.
The Ontario Research Foundation deals with problems in agriculture, veterinary science, textiles, chemistry, including fuels and ceramics, as well as metallurgy, the last being under O. W. Ellis. The metallurgy department completed the installation of equipment and is studying the effect of Ni in bronze, the effect of cold work on metals and alloys, and the reducibility of 6 Ontario iron ores.
Some 60 firms, through the Ontario Metal Industries Research Association, are coöperating with the Foundation. Work for the Association has included heat-treatment, study of hydrogen-welded products, fatigue of steel, sheet steel for enameling, high test cast iron, etc. Four metallurgical articles have been published. Distribution of technical information to inquiries forms an important part of the work. HWG(17)

Steel Mill Electrification. STRICKLAND KNEASS. *Electrical World*, Vol. 97, June 20, 1931, pages 1176–1179.
The new plant of the A. M. Byers Co., near Ambrigde, Pa., has an estimated ultimate capacity of approximately 45,000 tons of wrought iron products per month, made by a recently developed and perfected mechanical process. Practically all of the auxiliary and main machines are electrically-operated. Several units of the equipment are illustrated and briefly described. WHB(17)

The Dresden High-Pressure Heating Plant. (Das Hochdruck-Heizkraftwerk Dresden.) MAX WENGNER. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, May 1931, pages 129–139.
Discusses the plant of the Dresden Gas, Water and Electric Works as to its economic aspects, the choice of steam pressure, steam temperature and kind of fuel used. A description is given of the various buildings and the system under which they operate. Several pictures and diagrams are included. MAB(17)

10,000 Automobile Frames a Day. SIDNEY G. KOON. *Iron Age*, Vol. 125, June 5, 1930, pages 1665–1668, 1728.
Describes plant and equipment of the A. O. Smith Corporation, Milwaukee Wisconsin. Frames are made on automatically synchronized conveyors and coördinated machines. Within $1^1/_2$ hours time the following operations are completed: selecting and straightening steel strip, pickling, forming, attaching side bars, hangers and clips, assembling, riveting parts in complete frame, cleaning, painting and drying. Each piece is 8 seconds behind the next one. Plant is geared to 450 finished frames an hour. VSP(17)

Operating Details of an American Motor-Cylinder Foundry. A. LENZ. *Foundry Trade Journal*, Vol. 44, Apr. 23, 1931, pages 291–293.
Details of the operation of the Chevrolet foundry, Saginaw, Mich. OWE(17)

Illinois Constructs Commodious Materials Testing Laboratory. H. F. MOORE. *Iron Age*, Vol. 125, May 29, 1930, pages 1594–1597.
It is a four-story brick building. Plan is in the form of an H with 2 wings 50 × 187 ft. and a stem 92 × 110 ft. A new Emery-Tatnall 3,000,000 lb. testing machine ranks among the largest in the world. Other testing machines area 600,000 lb. Riehle, a 200,000 lb. Olsen machine, a 230,000 lb. Olsen torsion testing machine and a Turner impact testing machine. Other testing equipment is composed of 21 rotating beams, 3 for testing metals under repeated twisting, 2 for testing sheet metal, etc. VSP(17)

How to Figure Amount of Water Used by Hydraulic Presses. F. G. SCHRANZ & W. L. DELANEY. *Heating, Piping & Air Conditioning*, Vol. 3, February 1931, pages 135–136.
A very brief article relative to the determination of the quantity of water used for supplying hydraulic presses. A concrete example is given to illustrate just how determinations are made for a two pressure system, that is, a high and low pressure system. WAT(17)

Trends in the Design of Steel Mill Power Plants. F. H. DAMIELS. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 57–60.
Scattered steam drives and isolated small boiler plants are being rapidly replaced in the iron and steel industry by electric drives and central power plants. This is effecting great savings in fuel, maintenance, labor and general expenses. The power plants are fired mainly with blast furnace gas, pulverized coal or coke braize serving as a secondary fuel. Coke braize is utilized in separate boilers equipped with traveling grate stokers. Pulverized coal is handled either in the "bin system" or the "unit system." The very rapid development of "unit pulverizers" and their many obvious advantages over a large storage or bin system promises to make the unit system the preferred means of firing large boilers. JN(17)

Production Economy in Iron and Steel Works. Part 1. OTTO CROMBERG. *Iron & Steel Institute, Advance Copy* No. 5, May, 1931, 17 pages.
An example of a detailed time study is given. In many steel mill processes the rate of production is dependent on one particular operation, which is called the "bottleneck." Methods of management are discussed. JLG(17)

Field Laboratory for Outside Plant Studies. R. G. WATLING. *Bell Laboratories Record*, Vol. 9, July 1931, pages 529–534.
General description of the 85 acre extension of the outside plant laboratory and brief mention of research work of electric, ceramic and weather-proofing nature. Ha(17)

Casts Pipe in Eighteen Foot Lengths. PAT DWYER. *Foundry*, Vol. 58. Aug. 1, 1930, pages 104–109.
Describes plant and equipment of the National Cast Iron Pipe Co., Birmingham, Ala. VSP(17)

Casts Pipe Vertically in Sand. PAT DWYER. *Foundry*, Vol. 58, Sept. 1, 1930, pages 104–107.
Describes the general layout of the plant of the National Cast Iron Pipe Co., Birmingham, Ala. VSP(17)

MACHINERY & SUPPLIES (18)

Recent Trends in Individual A. C. Roll Table Drives. R. M. BAYLES (Westinghouse Electric and Mfg. Co.). *Iron & Steel Engineer*, Vol. 8, Mar. 1931, pages 96–97.
A. C. motors for the direct drive of hot bed roll tables are described. WLC(18)

Defects in Design and Tooling of Bearings. C. H. BIERBAUM. *Machine Design*, Vol. 3, Mar. 1931, pages 37–40.
The author points out that not infrequently the shapes of journal bearings are of such complicated construction that deformations take place. Simple, straight lines, no changes of section and the highest possible degree of accuracy are an economical advantage. Surfaces of bearing alloys composed of hard and soft crystals can be finished best by tooling with a sharp diamond cutter taking a depth of a final cut of 0.001 in. or less at a high speed. In this manner, surfaces can be produced that require only a minimum of running-in time. Ha(18)

The Lubrication of Ball and Roller Bearings in the Steel Mill. D. E. BATESOLE. *Iron & Steel Engineer*, Vol. 8, Jan. 1931, pages 8–12.
The author discusses the lubrication problems of various ball and roller bearing applications in the steel industry. WLC(18)

Roll Table Drives. F. E. HARRELL. *Iron & Steel Engineer*, Vol. 8, Mar. 1931, pages 97–100.
Discusses requirements of roll driving motors in relation to weight and spacing of rolls, conditions of heat, water and scale surrounding the table. WLC(18)

Machinery in the Steel Industry of the United States. F. L. ESTEP. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, pages 533–582.
Lists and comments upon mechanical devices in steel mills. HWG(18)

Electrical equipment of the Slabbing and Hot Strip Mills at the Wheeling Steel Corporation's Steubenville Plant. JAMES FARRINGTON & H. A. WINNE. *Iron & Steel Engineer*, Vol. 8, July 1931, pages 324–336.
The authors describe the substation installation and electrical equipment for the operation of 45″ reversing Universal Slabbing Mill and the Continuous Hot Strip Mill of the Wheeling Steel Corporation at Steubenville. Diagrams and photographs illustrate the layout and electrical connections. WLC(18)

Material Handling in Quantity Production Shop. NORMAN H. PREBLE. *Iron Age*, Vol. 127, June 4, 1931, pages 1806–1809, 1856.
Extract of paper presented at the Birmingham semi-annual meeting of the American Society of Mechanical Engineers. Most obvious purpose for installation of handling equipment is to reduce non-productive cost of moving the product as it passes through the plant. Other items of considerable importance are the increase in productive capacity of men and machines, and the decrease in inventory by keeping material constantly on the move. Reduction of damage is of importance. Type of handling equipment may be sub-divided into 2 classes—intermittent operation and continuous operation. Intermittent is the more inexpensive and more generally used. Overhead power driven trolley conveyor is the most flexible type. VSP(18)

Modern Rolling Mills for Light Metals. (Neuzeitliche Walzwerke für Leichtmetalle.) E. PFANN. *Metallwirtschaft*, Vol. 10, May 22, 1931, pages 427–428.
A rolling mill built recently in Germany for an American aluminum company is described in detail. It contains three rolls and has an ingot capacity of 1300 kg. CEM(18)

Brown-Boveri Mercury-Arc Power Rectifiers in Japan. J. J. STUDER. *Brown Boveri Review*, Vol. 18, May 1931, pages 181–182.
Gives reasons for use of the mercury-arc rectifier as most suitable converter for railways (particularly Japan) where traffic is seasonal. They are used in 1500-V plants, as well as in 600-V plants. MAB(18)

BIBLIOGRAPHIES (19)

Patent Literature on Chromium Plating. (Die Verchromung in der Patentliteratur.) R. JUSTH & F. MARKHOFF. *Korrosion und Metallschutz*, Vol. 7, Apr. 1931, pages 73–82.
Includes discussion. An exhaustive collection of patents on chromium plating irrespective of the commercial importance or "possibility of application." The authors accumulated "all patents granted or pending" in the following countries: Germany, Austria, England, U. S. A., France and Switzerland. The subject to which the patents refer is briefly but effectively pointed out and subdivided under the following head-lines: (1) Electrolytes based on chromic acid, (2) electrolytes composed of lower valence compounds of chromium, (3) molten salt electrolysis, (4) deposition of chromium alloys, (5) anodes, (6) anodic pre-treatment, (7) thermal treatment, (8) intermediate layers, (9) various processes, (10) protective layers on the surface of the baths, (11) chromium plating of commercial goods on a large scale, (12) application of chromium plating. On the Mechanics of the Plastic State of Metals. A. NADAI. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, 1930, *Applied Mechanics*, pages 193–216.

Includes discussion. A study of the mechanical conditions under which plastic flow in metals occurs. Rules relative to the stresses and the deformation when the stresses reach the limit of plasticity are discussed. Some cases of plastic flow with rotational symmetry around an axis in cylinders are considered. As examples, the case of a bar in combined tension and torsion and that of a hollow cylinder subjected to a high internal pressure and axial forces are treated. The cases of pure bending of a bar with a rectangular cross-section and of pure torsion of a bar with a circular cross-section are discussed, assuming a general law of deformation. Also application of this theory is made to the hollow cylinder subjected to internal pressure. Methods of finding the residual stresses after severe plastic deformation are discussed, and the results obtained in the study should throw light on the problem of these stresses. (20)

New Rolled Sections for Welded Cranes. (Neue Walzeisen für geschweisste Krane.) KARL MELCHER. *Die Schmelzschweissung*, Vol. 9, May 1930, pages 120–121.

The present standard sections of strucutral iron were adapted to fit the riveting process for joining them together. For welding processes, different sections would be more suitable and should be developed especially to diminish the work for preparation and welding. A few illustrations are given of such flat and half-cylindrical sections and a calculation shows how the stresses can often be reduced thereby. Ha(20)

Calculations of the Depth of Ferro-Magnetic Ores. (Beräkning av magnetiske malmers djupgaende.) TH. DAHLBLOUR. *Jernkontorets Annaler*, Vol. 115, March 1931, pages 95–102.

One of the poles of an ore magnet appears always to be situated close to the deepest point of the ore body, irrespective of the relation of dip and strike to the magnetic field of the earth. If the position of the lower pole can be determined, the approximate depth of the ore is consequently known. At a sufficient distance from the ore, the magnetic field may be considered to be approximately equal to that of an ideal magnet, and the author describes several methods by which the poles of the ore magnet may be found through measuring the direction of the field at different points on the surface. The best results are obtained by using curves drawn through points where the angle between the direction of the magnetic field and the axis of the magnet has the same value. HCD(20)

On the Attack of Metals by Insects. II. (Ueber den Angriff von Metallen durch Insekten. II.) O. BAUER & O. VOLLENBRUCK. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XVIII, 1931, page 1.

Welding by Piece Work. (Akkordschweissen.) H. W. NIESS. *Autogene Metallbearbeitung*, Vol. 23, Dec. 1, 1930, pages 374–376.

Discussion of piece work as compared with time work. In general, piece work is advocated for most cases. Ha(20)

The Utilization of the Blast Furnace Slag in Japan. S. OKA. *The Journal of the Society of Chemical Industry*, Japan, Vol. 34, Feb. 1931, pages 33B–34B.

Reviews article by M. Kahara in January issue of Kōgyō Kwagaku Zasshi. Production of the slag is increasing rapidly. Slag cement and slag mortar products are not promising; production of slag bricks is increasing; blast furnace slag cement and iron Portland cement are best and least expensive products; slag ballast simplest, oldest and largest consumer of slag: slag tar ballasts used as pavement material; slag blocks in trial state, but profitable. Design of Balancing Machine Commands Unusual Attention. E. L. THEARLE. *Machine Design*, Vol. 3, July 1931, pages 39–42.

The principle of this dynamical balancing method is based on the fact that any substantially rigid rotating body can be dynamically balanced correctly by the addition of 2 weights, one in each of 2 arbitrarily chosen transverse planes of the body. For this reason, the balancing machine consists of a hollow case which is attached to the body to be balanced and in which 2 balls are running freely. First the balance is made for one plane, then for the other. The unbalance of the body in rotation is counteracted by the balls moving in their race in such a way as to decrease the unbalance of the system. The position which the balls assume can be read on a scale and the necessary weight determined and the location fixed. The construction of the machine and the operation are described in detail. Ha(20)

Plant Vacuum Cleaning Safeguards Men and Machines. LESTER C. SMITH. *Iron Age*, Vol. 127, June 11, 1931, pages 1892–1895.

A central vacuum cleaning system renders at least 5 distinct services. They are: (1) rapid and thorough cleaning; (2) cleaning return tube and sectional boiler flues and the boiler room; (3) cleaning electrical and power plant equipment; (4) removal of dust at its source; and (5) removal of excess material in manufacturing processes. VSP(20)

The Making of a Carding-Engine Cylinder. B. SIMPSON. *Foundry Trade Journal*, Vol. 45, July 9, 1931, page 28.

Description, accompanied by 4 diagrams, of an economical method of producing a carding-engine cylinder. OWE(20)

75 Years of Steam Boiler Operation. (75 Jahre Dampfkesselwesen.) FRIEDRICH SCHULTE. *Archiv für Wärmewirtschaft und Dampfkesselwesen* Vol. 12, June 1931, pages 162–167.

Jubilee meeting of the Verein deutscher Ingenieure presents papers and discussion on the development of different kinds of boiler construction, the cylinder boiler, the fire-tube boiler, the fire-tube flue boiler, ship boilers, drumhead and vertical tube boilers. Overheating, preheating, storage tanks, furnaces, preparation of feed-water, boiler operation and supervision are also considered. The activities of the V. D. I. and the Dampfkessel-Überwachungs-Vereine are reviewed. MAB(20)

Things We Learn in the Laboratory. L. C. PAN. *Monthly Review American Electroplaters' Society*, Vol. 18, May 1931, pages 29–31.

Markets for Gases Electrolyzed with Off-Peak Power. PAUL MCMICHAEL. *Electrical World*, Vol. 97, June 20, 1931, pages 1182–1185.

Outlets for oxygen are well established and new markets for hydrogen make electrolysis of water economically feasible. Present and possible uses of O_2 and H_2 are mentioned. Tables show: (1) economical voltage for cell operation under various conditions, (2) electrolytic cell plant, capacity equivalent to 10,000 kw. a. c., and (3) availability of off-peak energy in the plant analyzed. Serious consideration may now be given to the use of electrolytic cells in the place of liquefaction equipment for the production of O_2 only. "Because of the great flexibility of operation possible with electrolytic cells and the fact that air liquefaction apparatus must be operated continuously if O_2 is to be made at a reasonable cost, the advantages of electrolytic cells with power only intermittently available are apparent." WHB(20)

Accident Prevention in the Autogenous Field. (Unfallverhütung auf dem Autogengebiete.) W. KEMSIES. *Die Schmelzschweissung*, Vol. 10, May 1931, pages 124–126.

Inexperience and carelessness cause about 90% of the accidents. It is important to make this evident to the personnel and to elucidate the special points which may give rise to dangerous conditions. A series of accidents are described and the manner in which they might have been prevented by carefulness is explained. Ha(20)

Fire Prevention on Aircraft. (Erhöhung der Sicherheit von Luftfahrzeugen durch Bekämpfung der Brandegefahr.) F. KÜHN. *Zeitschrift für Flugtechnik und Motorluftschiffahrt*, Apr. 14, 28, 1931, pages 197–206, 241–244; translated as *Technical Memorandum* No. 628, *National Advisory Committee for Aeronautics*, July 1931, 23 pages.

Seamless flexible metal tubes are easily broken by the continual vibration. Other types of flexible piping show promise. All fuel and oil pipes should be double, one pipe within another. No soldering of pipes should be permitted, as it makes the pipes brittle. Long pipes should have flexible connections. Sheet electron should not be used for engine cowling. If the thin magnesium alloy sheet starts to burn, various types of fire extinguishers are ineffective. The balance of the article relates to other than metallurgical problems. HWG(20)

The Systemization of Die Design Departments. O. B. JONES. *Metal Stampings*, Vol. 4, Jan. 1931, pages 45–46.

The value of the drafting department to the manufacturing plant should be appreciated. The draftsman and the shop man should coöperate in all new ideas with sympathy and understanding. The author deplores the periodic see-sawing of supremacy between die designing department and die maker observed in the sheet metal departments of several automobile plants. Is this perpetual shifting of authority necessary? JN(20)

The Use of Heat and Power in the Breweries. (Wärme- und Kraftverbrauch in Brauereien.) J. SCHLEMENSON. *Archiv für Warmewirtschaft und Dampfkesselwesen*, Vol. 12, June 1931, pages 169–173.

Investigation of the average-sized steam brewery: brewing process, carrying out of the investigation, the results of the tests on the steam boiler, on the steam engine, and on the rest of the machinery are described; the normal amount of heat used for 1 hectolitre of beer, the power consumed, and an evaluation of the heat balance and suggestions are given; the investigation of a small brewery with a direct heat copper is considered with reference to operating methods, testing of the steam boiler and the copper, and the heat consumed. A summary is made. MAB(20)

The Effect of Stirring on the Rate of Coagulation of Gold Sol. EMLYN JONES. *Transactions of the Faraday Society*, Vol. 27, Feb. 1931, pages 51–58.

Employing an apparatus which ensures more controllable conditions of stirring than those obtained by previous investigators the effect of agitating the sol, when in process of coagulation by various concentrations of electrolyte, is investigated. The results obtained are very complex. When the concentration of the electrolyte is such as to ensure conditions of rapid coagulation, stirring produces a decided accelerating influence. Such an accelerating effect is attributed not simply to the increase in collision frequency between the particles of the sol, but likewise to the aeration or formation of air bubbles in the sol. The conditions existing in such aeration are likely to be favorable to aggregation. When the concentration of the electrolyte is such as to give rise to slow coagulation of the gold sol, stirring is found to have a retarding or inhibitive effect on the coagulation. This may be accounted for by a disruption or displacement of the "imperfect" or incomplete outer layer of the double layer, giving rise to temporary but effective increase of charge and, therefore, to a decrease in coagulation velocity. The work was carried out in the Department of Physical Chemistry in the University of Liverpool. WAT(20)

Rapid Calculation of Bearing Loads Can Be Made with Simplified Forms. I. and II. ROBERT N. JANEWAY. *Automotive Industries*, Vol. 64, May 30, 1931, pages 831–838; June 6, 1931, pages 875–879.

Tremendous time-saving in determining pressures is made possible by using simple arithmetic processes with charts shown. The first requisite for simplifying the calculation is the reduction in the number of points at which the resultant force must be obtained during the cycle. The proposed method resolves all forces into vertical and horizontal components and uses the true mean values of each component over any given interval to obtain the mean resultant force for the interval. WHB(20)

Metallurgical Laboratory at Twelfth Aviation Exposition. (Le laboratoire de métallurgie du XIIe salon de l'aviation. 28 Novembre-14 Décembre 1930.) JEAN GALIBOURG. *Revue de Métallurgie*, Vol. 28, June 1931, pages 330–347.

One of the characteristic features of this exhibition is the presentation of the contemporary developments of the metallurgy and the applied sciences. In the present exhibition the work of the different scientific committees and societies was presented together with the demonstration of metallurgical processes made during the recent years. A detailed description of the activities of this section of the exposition is given. JDG(20)

Destruction of Metals by Insects. (Metallzerstörungen durch Insekten.) DR. FREITAG. *Oberflächentechnik*, Vol. 7, Oct. 7, 1930, pages 184–185.

Recent tests have shown conclusively that certain insects can really destroy metals. Two beetles, especially, (dermestes peruvianus and dermestes lardarius) destroy materials of lead. In 4 hrs., they could bore through a plate 0.2 mm. thick. The same was shown to be true in the case of tin; but brass, zinc and aluminum were proof against destruction in this manner. The destruction is by biting and is purely mechanical. See also "On the Attack of Metals by Insects," *Metals & Alloys*, Vol. 2, Feb. 1931, page 46. Ha(20)

Sucker Rods, A. P. I. Specifications. C. N. BOWERS & B. B. WESCOTT. *Petroleum Engineer*, Vol. 2, May 1931, pages 81, 84, 86, 89, 93, 96, 98.

Reasons for standardization of equipment, and the A. P. I. sucker rod specifications. (20)

Cylinder Wear and Its Cure. C. E. BAXTER. *Motor Transport*, England, Vol. 52, Apr. 27, 1931, pages 473–474.

Cylinder wear or the matter of piston fit has become important and so it is fortunately possible to incorporate into existing engines, without much cost and trouble, the latest advances which have been made in this direction. As time goes on harder cylinders or liners will add further advantages. Modern science is providing the necessary solution, both in the way of alloys and finishing methods. WHB(20)

FOUNDRY PRACTICE & APPLIANCES (22)

Correlation of Mechanical Tests Involves Many Difficulties. J. G. Pearce. *Foundry*, Vol. 58, Oct. 15, 1930, pages 62–65, 70; Nov. 1, 1930, pages 93–97.

Exchange paper of the British Foundrymen and presented before the American Foundrymen's Association, Cleveland. Explains some of the reasons for the variations in the factors governing the production of cast Fe. Simple procedures underlying investigations on cast Fe are: (1) effect of variations in composition on properties of cast Fe may be studied by testing bars of same size, but with variations of composition; (2) effect of variations in rate of cooling on properties may be studied by testing bars of different sizes; (3) effect of variations in melting conditions may be studied by testing bars of the same size and composition under varying melting conditions. Part 2 discussed the effect of varying melting conditions, change of strength with section and composition and interpretation of deflection figure in transverse test. VSP(22)

Overcome Alloy Ingot Trouble. W. E. Paulson. *Foundry*, Vol. 58, Aug. 15, 1930, page 60.

Describes difficulties encountered in producing non-ferrous castings using alloy ingots. From results obtained author concludes that virgin metals or their equivalent are absolutely essential for production of best quality castings. See *Metals & Alloys*, Vol. 2, Apr. 1931, page 87. VSP(22)

Briquetting of Cast Iron Borings and Steel Turnings. A. K. Nowak (Baldwin-Southwark Corp.). *American Metal Market*, Vol. 38, Apr. 21, 1931, pages 11–12.

Presented at A. S. M. E. 2nd National Industrial Congress, Cleveland, O., April 1931. Losses due to oxidation and slagging off during remelting of scrap cast iron borings and steel turnings are high. Briquetting practically eliminates losses. Material compressed to reduce proportion of surface to weight and thus bring oxidation effect on compressed blocks to minimum. Two commercial machines described. In tests of melting briquettes in the cupola, no difference noted in physical and chemical properties of produced metal. No change in % of good castings and scrap, using as high as 21% briquettes in the charge. DTR(22)

The Production of High-Test Cast Iron. Richard Moldenke. *Iron & Steel of Canada*, Vol. 14, Jan. 1931, pages 1–19; Feb. 1931, pages 27–28, 41–42.

After reviewing the character of high-test cast iron, particularly the manner in which the graphite present in this material is distributed, Moldenke refers to methods of arriving at the desired structures. The next part of the paper is taken up with a discussion of what had been done prior to the discovery of the basic principles involved in the rational production of this material. A very complete description of the cupola process is included in this article, and its disadvantages are discussed. The second part of this article deals with the methods adopted in the manufacture of high-test cast iron. Electric furnace process and its products are compared with the fuel-fired furnace and its products. Details of the electric furnace process are very fully discussed. OWE(22)

Cupola Melting of Bronze. E. R. Darby. *Metal Industry*, New York, Vol. 29, Mar. 1931, pages 111–112.

From *Metals & Alloys*, Nov. 1930, pages 812–813. A description is given of a shaft type furnace for high speed melting of bronze. The furnace holds 500 lbs. of metal and melts 2500 lbs. of metal per hour. The success of this furnace depends on the use of a newly developed pitch coke of exceptionally high purity. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 83. PRK(22)

The Constant-Air-Weight Method of Cupola Blowing. Part I. H. V. Crawford (General Electric Co.). *Iron and Steel Engineer*, Vol. 7, Dec. 1930, pages 559-565.

The author describes his method of supplying air to the cupola by weight, operation of the cupola, and the electrical equipment for automatic control of the weighed air supply. WLC(22)

Cupola Melting of High Test Cast Iron. F. B. Coyle (International Nickel Co.). *Metal Progress*, Vol. 19, Feb. 1931, pages 47–50.

Abstract of a paper to be presented before the Western Metal Congress, San Francisco, Feb. 16, 1931, and to be published in full with discussion in the Transactions. The constitution of gray iron is analyzed as an aggregate of steel and graphite and 3 factors affect its strength, (1) amount, size and distribution of the graphite, (2) amount of cementite and (3) amount of alloy in the steel-like matrix. By proper control of these factors gray iron of varying degree of superior strength can be obtained up to 50,000 lb./in.^{2} Graphite particles must be small and uniformly distributed, the total carbon must be low. To attain this without oxidation high percentages of steel scrap in the charge and careful operation of the cupola are essential. Details of charge and the cupola operation are described. The properties, composition, and applications of such high strength gray irons are reported and discussed. WLC(22)

Cast Iron. Report of A. S. T. M. Committee A-3, H. Bornstein, Chairman. *Preprint* No. 11 for June 1931 Meeting, *American Society for Testing Materials*. 3 pages.

Progress report of committee and sub-committee. HWG(22)

Practical Cupola Control. (Misure pratiche per il controllo dei cubilots.) G. Conti. *La Metallurgia Italiana*, Vol. 23, May 1931, pages 390–399, 13 references.

Discusses measurement of blast, analysis of combustion gases, and pyrometry of gas and of molten metal. Most of the discussion is based on articles by Carra and Fric (*Chaleur et Industrie*, Dec. 1927 and Jan. 1928) and by Wensel and Roeser (*Foundry Trade Journal* 39, 1928, page 245, *Trans. A. F. A.*, Vol. 36, 1928, page 191). Temperatures in a few cupola runs are plotted. HWG(22)

Electric Process Iron for Cylinder and Cylinder-Head Castings. H. E. Bromer (Standard Foundry Company.) *American Metal Market*, Vol. 38, May 12, 1931, pages 11–12.

Paper presented at Annual Convention American Foundrymens' Association, Chicago, May 1931. Gives duplexing and continuous cold-melting processes, showing ease of control of carbon and silicon, uniformity in chemical analysis, hardness of cylinder blocks and physical properties. Gives electric furnace iron alloys and properties. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. DTR(22)

The Effect of Excessive Atmospheric Moisture in Cupola Blast. Neil A. Moore. *Foundry Trade Journal*, Vol. 44, May 28, 1931, pages 375–376, 378.

Paper presented to the Chicago Convention of the American Foundrymen's Association. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. OWE(22)

The Life of Malleable Cast Iron. *Foundry Trade Journal*, Vol. 44, May 28, 1931, page 374.

Abstract of article by E. K. Widin and N. G. Girschowitsch (*Die Giesserei*, 1930, No. 47) on the fluidity of malleable cast iron. The method adopted by these authors involved the use of a molded spiral. The factors, coal dust content, water content, and strength of molding sand, were investigated in this connection as were also the height of the gate, and the dimensions of the gate and of the casting. OWE(22)

The Conditions of Absorption and Oxidation in Small Cupola Furnaces at the Melting of Steel Scrap. (Zu-und Abbrandverhältnisse beim Einschmelzen von Stahlschrott im kleinen Kupolofen.) E. PIWOWARSKY, H. LANGEBECK & H. NIPPER. *Die Giesserei*, Vol. 17, Mar. 7, 1930, pages 225–230; Mar. 21, 1931, pages 275–280; Apr. 11, 1931, pages 352–360.

An experimental plant and some tests to determine the influence of the most important operating factors are described. The furnace had 300 mm. diameter. Briefly, the results are: (1) the amount of air supplied per minute has practically no influence on the carburization of the scrap but sulphur increases with increasing air velocity and quantity and the reduction of Si and Mg increases somewhat with increasing amount of air; (2) the carburization depends to a certain extent on the amount of coke per charge, an increase of the latter increases also the carburization zone and sulphur increases in the same ratio; (3) additions of normal slag did not show any influence on the carburization but it favored the absorption of sulphur and the burning of Si and Mg; (4) the operation of the furnace was investigated for melting with continuous iron flow, melting with discharges from time to time and melting at reduced height and amount of coke with continuous iron flow. Carburization is highest for the first method and lowest for the third. No influence could be stated for sulphur. The burning of Mg and Si was least for the second. The more scrap, the higher was the carburization and sulphurization but the lower the burning of Mg and Si. All experiments were described in detail. Ha(22)

Electric-Furnace Cast-Iron. H. E. BROMER. *S. A. E. Journal*, Vol. 29, July 1931, pages 85–89.

Melting in the electric furnace is the only means by which gray iron can be produced in quantities under absolute control, according to the author. Good iron can be produced from a cupola, but the cupola cannot be depended upon to produce uniformly good iron. Expensive alloys, which have been used to improve the quality of the cupola iron for cylinder-blocks, can be eliminated by the electric-furnace method. Results of tests of iron from regular electric-furnace production are charted and tabulated and comparisons are made with products of the cupola in the matter of Brinell hardness. Micrographs of the electric-furnace and cupola iron are given for comparison, and the significance of the difference in their structure is explained. Electric-furnace iron is said to be desirable for brake-drums, fly wheels and piston rings, as well as many other parts besides the cylinders and cylinder-heads which are considered more particularly in this paper. A great development in this method of melting during the next few years is predicted. The discussion brings out the importance of Brinell readings or some other method of measuring hardness of cast iron. Hardness and wearing qualities are said to be much influenced by the handling which the casting receives in the mold. Superheating iron and pouring it at high temperatures contribute to uniformity of structure and minimize internal strain. Cost of iron melted first in the cupola and finished in an electric furnace is said to be approximately the same as that of cupola iron. Scrap iron can be used in the electric furnace, without the addition of pig, because the sulphur content is not increased in the process. One discusser reports at length observations gathered during a tour in which many of the leading automotive foundries were visited. Ha+WAT(22)

The Brackelsberg Process for the Production of Grey Iron. P. BARDENHEUER. *Foundry Trade Journal*, Vol. 44, Apr. 23, 1931, pages 287–290.

A very complete description of the Brackelsberg process, including details of melting costs and of experiments in which charges of various types were employed. The article is accompanied by 9 photographs, 2 diagrams, and 3 tables. OWE(22)

The Laboratory and the Foundry. R. ARZENS. *Foundry Trade Journal*, Vol. 44, June 18, 1931, pages 413–414.

A brief paper dealing with the contribution which the laboratory can make to foundry practice. Reference is made to the improvement of the quality of the raw materials entering the foundry, of the finished products leaving the foundry, and of melting practice, as well as to laboratory and shop equipment essential for success in laboratory control. OWE(22)

Compact Foundry Handling System. SIDNEY G. KOON. *Iron Age*, Vol. 125, Apr. 10, 1930, pages 1069–1072, 1124.

Describes a combination of a vertical loop handling sand and a horizontal loop handling for molds and castings system of the General Electric Co., Pittsfield, Mass. Equipment was made by the Chain Belt Co. VSP(22)

Some Observations on the Preparation and Use of Synthetic Sand. L. B. KNIGHT. *Foundry Trade Journal*, Vol. 44, May 28, 1931, pages 367–368.

Paper read before the Chicago convention of the American Foundrymen's Association. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. OWE(22)

Teaching Pattern Design at the University of Illinois. B. RUPERT HALL. *Foundry Trade Journal*, Vol. 44, May 28, 1931, page 365.

A brief article, accompanied by one photograph, dealing with the course in pattern design which is given at the University of Illinois, in which the work is carried on entirely in the drafting room, using free-hand sketching and mechanical drawing. Hall states that it has been found possible for engineering students to get by this method of instruction from four to five times the amount of technical knowledge acquired by the making of actual patterns in the laboratory. OWE(22)

Gating Iron Castings. E. M. Handley. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, page 242.

Discusses the value of gating to the jobbing shop and deals with two things which must be known about any job before calculating the gating area—namely, the metal thickness and the weight. Dietert's formulas for calculating the effect of sprue height and the area of the choke are given. Reference is also made to pouring temperatures. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. OWE(22)

Making a Large External Part of a Friction Clutch in Dry Sand. A. GREENHALGH. *Foundry Trade Journal*, Vol. 44, Apr. 9, 1931, pages 263, 265.

Description of the manufacture of a friction clutch 72 in. in diameter and weighing approximately $3^1/_2$ tons. OWE(22)

An Italian Sand-Preparing Plant. J. CUNNINGHAM. *Foundry Trade Journal*, Vol. 44, June 25, 1931, pages 432, 440.

Describes sand-cleaning and sand-mixing machines manufactured by the Stabilimenti Tema, of Turin. The article is illustrated by 2 photographs and 1 diagram. The plant comprises a used-sand hopper; a new-sand hopper; rotating, feeding and proportioning plate; a bucket elevator; continuous sand-cleaning machine; and continuous tempering and mixing mill. OWE(22)

The Desulphurizing and Refining of Grey Cast Iron with Soda Ash. E. W. COLBECK & N. L. EVANS. *Foundry Trade Journal*, Vol. 44, Apr. 30, 1931, pages 305–307.

An article, accompanied by 4 photomicrographs and 5 tables, dealing with results of experiments on the use of soda ash. OWE(22)

The Fundamentals of Brass Foundry Practice, Part 26. R. R. CLARKE. *Metal Industry*, N. Y., Vol. 29, July 1931, pages 302–303.

Nickel additions harden and strengthen copper alloys. Molds for copper alloys high in nickel require highly refractory sand faced with plumbago; also large feeding gates and risers. For nickel silver the sand should be dry and the metal hot. Aluminum and magnesium are common deoxidizers, but silicon is used with 50–50 copper nickel alloys intended for electrical purposes. PRK(22)

DETROIT Rocking Electric FURNACES

Small (250 lb.) Detroit Electric Furnace Pouring Heat of Alloy Steel

These furnaces manufactured in capacities from 250 lbs. per hour to 6000 lbs. per hour, offer unusual economy in the production of grey iron, malleable iron, alloy steel, or non-ferrous castings showing the highest possible quality. The rocking action of the

DETROIT ELECTRIC FURNACE

insures complete homogeneity and uniformity, as well as physical characteristics of a highly superior character in the finished castings. Over 50 DETROIT ELECTRIC FURNACES are in use in melting or duplexing grey iron or alloy steel, and over 400 furnaces are in use in the non-ferrous foundries throughout the world.

We will be pleased to send you complete information regarding these remarkable furnaces.

DETROIT ELECTRIC FURNACE COMPANY

827 West Elizabeth St.

DETROIT MICHIGAN

Testing of a Cupola Furnace. (Onderzoek naar de werking van een koepeloven.) T. W. SIERTSEMA. *De Gieterij*, Vol. 5, Apr. 1931, pages 44–47.

Graphs are presented which give as a function of the time from the beginning of the operations: (1) the weight of each charge, (2) the temperature of the charge, (3) the statistical wind pressure and (4) the volume of air in m^3. The curves show plainly the importance of a continuous melting process without interruption of the wind pressure. The general results agreed satisfactorily with those given by Piwowarsky in his book on high test cast iron. HSvK(22)

Cupola High-Test and Alloy Irons in a Machine Tool and Gray Iron Jobbing Foundry. L. M. SHERWIN & T. F. KILEY. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, July 1931, pages 115–160; *Foundry Trade Journal*, Vol. 45, Aug. 13, 1931, pages 102–104.

See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. CHL + OWE(22)

Cupola Malleable Cast Iron. H. H. SHEPHERD. *Iron & Steel Industry & British Foundryman*, Vol. 4, Feb. 1931, pages 151–152; Mar. 1931, pages 199–200; Apr. 1931, pages 251–252; May 1931, pages 281–282.

While it is not claimed that malleable cast iron possesses as good physical properties as air furnace iron, it readily adapts itself to continuous foundry operation; it is less costly and it tends to be more sound and free from shrinks. Statements regarding the types of pattern, core and mold equipment required, the properties of core and molding sands and the composition requirements of the metal are made. CHL(22)

Measuring Temperatures of Molten Metal in the Brass Foundry. H. H. ST. JOHN. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, May 1931, pages 35–44.

Author presents a discussion on the need for controlling pouring temperatures of non-ferrous metals. Types of pyrometers available are described together with precautions to be taken in their maintenance and use. CHL(22)

Patternmaking and Its Relationship to Design and Foundry Practice. M. RUSSELL. *Foundry Trade Journal*, Vol. 44, Apr. 9, 1931, pages 253–256.

Paper, with discussion, dealing with patternmaking. Special attention is paid to the competition with welded structures, now being encountered by foundrymen, and means are suggested whereby it may be met. The paper is accompanied by 13 diagrams. OWE(22)

The Gating and Pouring of Castings. E. V. RONCERAY. *Foundry Trade Journal*, Vol. 44, May 28, 1931, pages 369–371.

Deals with the factors affecting shrinkage, the principal types of gating, and the three essential considerations in pouring—temperature, speed, and evacuation of gas from the mold. The paper is accompanied by 2 photographs and 5 sketches. OWE(22)

Factors Which Influence the Surface Quality of Gray Iron Castings. W. G. REICHERT & D. WOOLLEY. *Transactions & Bulletin Amercan Foundrymen's Association*, Vol. 2, Aug. 1931, pages 205–234.

See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. CHL(22)

The Relationship Between the Engineering and the Foundry Trades. L. H. POMEROY. *Foundry Trade Journal*, Vol. 45, July 9, 1931, pages 25–27.

A paper read before the Birmingham Convention of the Institute of British Foundrymen, in which the application of cast iron to the automobile trade is largely the basis of discussion. The author refers to early work on cast iron and to more recent work on the production of non-ferrous castings. Some attention is directed to the question of wear and to the problem of materials required to resist pressures of the order of 1,000 lb./in.^{2} Criticism of certain research work is made, and the necessity of considering stiffness in connection with engineering design, rather than mere tensile strength, is discussed. Some attention is directed to the economics of the foundry industry and comparison made between methods of working in the United States and Great Britain. OWE(22)

Recent Developments in Cast Iron Foundry Practice in Great Britain. J. G. PEARCE. *Metallurgia*, Vol. 4, June 1931, pages 55–60.

From a paper presented at the annual conference of the Institute of British Foundrymen. Describes work of British Cast Iron Research Association. JLG(22)

Mechanizing a Giant Foundry. J. B. NEALEY. *Scientific American*, Vol. 145, 1931, pages 44–45.

Bringing the variables under closer and closer control is an ever-present problem in foundry technique. New ideas and equipment with this purpose in view are being constantly devised and put into use. This modernization of foundry practice has been carried on at two foundries of the Allis-Chalmers Mfg. Co., Milwaukee, Wisconsin, to a remarkable degree. This company manufactures gas engines, steam engines, turbines, condensers, air and gas compressors, tractors, mining machinery, and many other large unit machines, as well as special work. Castings as large as 125 tons are made of a single pouring. Metal is furnished by six cupolas. All pouring is direct from cupola to flask with crane service, and ladles of $1^1/_2$ to 30 tons capacity. Hand, machine, pit and loam molding are all employed. One of the most noticeable features is the absence of smoke and dirt in the air. Carefully prepared sand is elevated by bucket conveyor to hoppers which drop it onto belt conveyors which take it to points just over the core makers where it drops by gravity and through chutes directly into core boxes on molding machines. The feed is started and an automatic device shuts off the flow when the correct amount has been furnished. One of the unique pieces of equipment in this foundry is an especially designed washer where the cores and sand are forced out of the casting hydraulically and at the same time the castings are cleaned. Four pictures show the general arrangements. WAT(22)

Pattern-Making. (Der Modelbau.) RICHARD LÖWER. Julius Springer, Berlin, 1931. Cloth, $6^1/_2 \times 9^1/_4$, 229 pages. Price 17.50 RM.

This description of the making of wood patterns is so profusely illustrated that it will be useful even to those who have little German.

The writer recognizes that there are two distinct problems in making patterns and core boxes, depending on whether they are for permanent use, or whether only a very few castings are to be made. Correct and erroneous methods of woodworking and of construction of patterns are shown by sketches.

Diagrams of hundreds of types of patterns are shown for different methods of molding. Any pattern maker can find much that will be helpful in the volume, but it will be difficult for him to locate it, since there is no index and the table of contents is not very detailed.—H. W. Gillett (22)-B-

Some Developments in Modern Foundry Practice. E. LONGDEN. *Foundry Trade Journal*, Vol. 44, Apr. 9, 1931, pages 259–262; Apr. 16, 1931, pages 277–280.

Discusses various processes for the production of high-test cast iron—namely, the Lanz, the Emmel and Meehanite. Considerable space is given to the discussion of melting furnaces, including the Poumay cupola, the balanced-blast cupola patented by the British Cast Iron Research Association, and the Brackelsberg rotary furnace. Some attention is directed to mechanical cupola-charging plant, to sands and refractories, and to core- and mold-drying plant. Special mention is made of the molding of a 20-ton hydraulic cylinder casting. The article concludes with a description of a continuous casting plant and with brief notes on core-making, sand-casting machines, and the dressing of castings. The article is accompanied by 15 photographs and 3 diagrams. OWE(22)

FURNACES & FUELS (23)

Loss of Heat and Life of Roof of Open-Hearth Furnaces. ALBERT SCHÜSTER. *Iron Age*, Vol. 127, June 18, 1931, pages 1976–1978.

Translated from article in *Stahl und Eisen*. Gives results of study of factors influencing life of open-hearth roof, based on temperature measurements at various points in the roof at occasional intervals. Roof heat losses rise about threefold from the beginning to the end of measurements, in relation to total heat consumption of furnace—from 3.21 to 8.5%. Proportion of roof loss to heat consumption of hearth increases from 8.89 to 22.6%. Depth of penetration of heat into brick is proportional to the thickness of the brick. Resistance of roof to attack of slag, lime or dust is of great importance. Danger of burning off depends on flow of gases and their control and not on thickness of bricks. VSP(23)

Gas Producers for Continuous Operation. (Gaserzeugungsöfen für stetigen Betrieb.) A. SANDER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, June 13, 1931, pages 746–750.

The development of the continuously operated chamber furnaces have made it possible to simplify and cheapen the cost of gas production. A few modern types are described and compared with regard to their performance. Four references. Ha(23)

Slagging of Hot Surfaces. (Verschlackung von Heizflachen.) P. ROSIN. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Mar. 1931, pages 81–83.

Paper presented at Düsseldorf, Jan. 7, 1931. Discusses the formation of slag deposits and the means for removing them. Outlines the test methods for determining the behavior of ash when striking against hot surfaces. MAB(23)

Furnaces for High Temperatures. (Oefen für hohe Temperaturen.) ST. REINER. *Chemische Fabrik*, Mar. 19, 1930, pages 85–86.

Places emphasis upon the heat conductivity of the refractory material and outlines the construction of a furnace used for temperatures as high as 2200° C. EF(23)

Self Regulating Induction Furnace with a Ferromagnetic Muffle. (Four à induction á moufle ferromagnetique autoregulateur de temperature.) R. PERRIN & V. SORREL. *Journal du Four Electrique*, Vol. 40, May 1931, pages 168–169.

A muffle furnace is proposed consisting of a ferromagnetic muffle surrounded by an envelope made of a ferromagnetic substance which becomes non-magnetic at the maximum operating temperature of the furnace. The combination is properly heat insulated and placed into an induction coil of copper wire fed with an A.C. line of the usual frequency. Induction currents raise the temperature of the envelope and the muffle itself until the temperature is reached at which the envelop becomes non-magnetic. The coil is so adjusted that the amount of heat developed by induction in the muffle alone is sufficient for taking care of the heat losses thereby keeping the furnace at a constant temperature. Ferro-cobalt and ferro-nickel alloys are a suitable material for the muffle and its lining. The temperature reached is but little affected by the changes in amperage, and with a moderately uniform current will remain practically stationary. The furnace used had a cylindrical muffle 150 mm. diameter, 350 mm. long and 12 mm. wall thickness made of 30% Fe-Co. The liner was made of 3 mm. Ni sheet and the coil consisted of the three layers of copper strip 10 by 3 mm. Using a 50 cycle current and varying its amperage from 40 to 120 amperes the temperature of the furnace was kept between 946 and 972°. The range of alloy steels available at the present would permit the making of these furnaces to cover temperatures from 15° to 1100°. JDG(23)

Tests on and Conversion of an Oil-Fired Annealing Furnace. (Untersuchung und Umbau eines Glühofens mit Masutheizung.) I. M. RAFALOVITSCH. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, May 1931, pages 141–144.

Description of a newly established method for equalization and optional regulation of the temperature of an oil-fired heating furnace. MAB(23)

Heat Exchange in Regenerators. (Der Wärmeaustausch in Regeneratoren.) EM. LUBOJATZKY. *Metall und Erz*, Vol. 8, May 1931, pages 205–214.

Contains 12 references. A theoretical discussion covering the development of the physical laws of heat exchange, calculation of the heat exchange number for convection and conduction, calculation of heating surface in heating chambers, heat currents and heat endurance in regenerators and the influence of gas radiation on heat exchange. Steel Furnace Repairs. WALTER LISTER. *Metallurgia*, Vol. 4, July 1931, pages 97–99.

Detailed directions for repairing both basic and acid open-hearth furnaces. In keeping the bottom in repair it is essential to rabble out all steel before making new bottom. Electric furnace repairs are also mentioned. JLG(23)

On Blast Furnace Coke and Fire Bricks for the Iron and Steel Industries of Japan. T. KURODA. *Proceedings World Engineering Congress*, Tokyo, 1921, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 133–161.

Coking practice and analyses of coals and cokes, and the methods of making refractories in Japan are given. HWG(23)

Heat Required by a Lacquer Furnace. (Wärmebedarf von Lackieröfen.) W. NÖTTING. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, June 1931, pages 175–178.

Presents the basis for calculation of the heat required for a lacquer furnace and also the conversion of a charcoal furnace into a gas furnace. MAB(23)

High Frequency Steel Furnaces. D. F. CAMPBELL. *Rolling Mill Journal*, Vol. 5, Jan. 1931, page 64.

Paper presented before the British Iron and Steel Institute. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 16. JN(23)

The Large Electric Furnace Plant of the Adlerwerke. (Die elektrische Gross-Ofenanlage der Adlerwerke.) U. ASCHMANN. *Elektrotechnische Zeitschrift*, Vol. 52, June 18, 1931, page 823.

Cementing, refining and hardening furnaces of small parts for automobiles, typewriters and bicycles are described. Eight furnace chambers in double and single units of 100 KW 220 volts/unit are installed. Ha(23)

A Small Stationary Furnace for Aluminum Melting. ROBERT J. ANDERSON. *Industrial Gas*, Vol. 9, Mar. 1931, pages 15–17; *Brass World*, Vol. 27, May 1931, pages 104–106.

Description of the construction of a reverberatory furnace of 2000 lb. fired by natural gas. The temperature can be raised from room temperature to 760° C. in 30 minutes. It takes about 2 hrs. to melt 2000 lbs. of aluminum. Ha+WHB(23)

Furnaces for High Temperatures. (Oefen für hohe Temperaturen.) J. D'ANS. *Chemische Fabrik*, Feb. 5, 1930, pages 41–43.

Gas-fired filled with magnesium oxide. Crucible made of zirconium oxide. Reaches 2200° C. in about 45 minutes. EF(23)

Coke Oven Operation and Maintenance. F. J. PFLUKE. *American Gas Journal*, Vol. 134, Jan. 1931, pages 50–53.

Describes maintenance of the instruments, proper draft setting, a simple apparatus for pyrometer checking, the measurement of the flue temperature, determination and use of cooling curves, regenerator inspection, oven and flue pressure balance, and the reversing mechanism. MAB(23)

Automatic Regulation of Arc Furnaces (Le reglage automatique des fours á arc). GABRIEL DURAND. *Journal du Four Electrique*, Vol. 40, May 1931, pages 171–174.

After some theoretical consideration on the efficiency of arc furnaces a simple and effective electrode regulator is described. Their control is achieved, at present, by individual and rather powerful motors supplied with many fixtures for prevention of the effects of non-uniform action. The hydraulic regulator proposed requires a single motor running all the time at full capacity and activating a pump feeding the cylinders, the pistons of which are connected by the proper means with the electrodes. A relay closes or opens the orifice controlling the flow of water for any given cylinder. A very accurate and effective control is possible with this device. JDG(23)

Heat Treating Furnaces. FRED GROVE-PALMER. *Metal Industry*, London, Vol. 38, May 22, 1931, pages 521–522, 526.

A general description of some modern all-electric furnaces and auxiliaries is given. PRK(23)

Electric Melting Pots Have Been Simplified. P. H. CLARK. *Electrical Manufacturing*, Vol. 7, June 1931, pages 48–50.

The author is in the industrial heating engineering department of the General Electric Company. Immersion electric heating units have made melting pots both simple in construction and efficient in operation. Thus the electric melting pot has become a more practicable production tool because first cost is reduced, special pots are easier to produce, upkeep is greatly reduced, and first costs are considerably lowered. The pictures of various types of units are shown. WAT(23)

Industrial Furnaces for Gas. I. Metal Pot Furnaces for Soft Metal Melting. II. Crucible Furnaces. III. Special Furnaces for Metal Melting and Reduction. LAWRENCE E. BIEMILLER. *American Gas Journal*, Vol. 134, Feb. 1931, pages 34–36; Mar. 1931, pages 36–39; Apr. 1931, pages 46–48.

I. The metals melted in a metal pot furnace are lead, tin, babbitt, zinc, solder, type metal, white metal alloys and aluminum. They all melt well under 1000° F. The advantages of the tilting type furnace are given. II. Considers furnaces with crucibles, mainly graphite crucibles. They operate at higher temperatures than metal pot furnaces. They are used for melting brass, copper, gold, nickel, Monel, etc., as well as precious metals. It is desirable to use a tilting type furnace. Describes the most recent development in brass melting, the Rotary Brass Melter developed by the American Gas Furnace Company and the American Gas Association. The casting of brass and other metals is often desirably accomplished with a ladle or insulated crucible. III. Considers special furnaces used in the printing industry, for metal coating such as galvanizing, and for metal reduction. MAB(23)

Heating-Element Deterioration Reduced in Cyanide Furnace. R. E. JAMES & GLENN COLEY. *Electric World*, Vol. 97, June 6, 1931, pages 1057–1058.

Field observations and laboratory experiments indicate that: (1) cyanide or its components have a deleterious effect upon Cr-Ni alloys; (2) the reaction between cyanide and Cr-Ni alloys increases rapidly with an increase in temperature and approximately 1650° F. is the maximum safe temperature for economical operation; (3) it is not economically practical to exclude cyanide or its components from the element chamber; and (4) the deterioration of Cr-Ni heating elements heated in air is exceedingly slow (at temperatures below 1800–2000° F.). From these conclusions, the deterioration of the heating elements is explained. An experimental furnace of air circulation type was designed and built by the research laboratory of the Detroit Edison Co. and placed in the plant of the Gemmer Mfg. Co. for a life and production test. The input of the test pot was 43 kw. and after 1800 work-hours' service, the input was 42.5 kw. No scale was found around the elements but traces of leakage were evident and a heavy deposit, apparently cyanites, was found on the floor of the entire chamber. Electric and physical examination showed no deterioration of the elements. There was a lack of appreciable quantities of the black smudge which usually forms on the surface of molten cyanide. It is believed that this smudge is a cyanite caused by the oxidation of the cyanides and is suppressed by the lower temperature differential and uniform heating of this type of pot. The new pot is shown in elevation and section and is described. WHB(23)

The Coreless Induction Furnace in the Steel Industry. E. F. NORTHRUP. *Iron & Steel Engineer*, Vol. 8, May 1931, pages 210–215.

A paper presented at the A. I. & S. E. E. Electric Heating & Welding Conference, Pittsburgh, Pa., Jan. 21, 1931. Inductive electric heating is more versatile in application than other electric methods of heating. It is superior to any other known method for the direct conversion of electric energy into useful heat. Several typical and representative installations are briefly discussed. The lines of commercial development of coreless inductive heating are listed as: (1) more and larger ferrous metal melting furnaces, gradually displacing the arc furnace melting; (2) heating to forging temperature of symmetrically shaped metal bodies in increasing quantities and the maintaining of temperature in hot steel billets as pushed from the molds and replacing the soaking pit; (3) heating to an annealing temperature stacked piles of thin sheet steel; (4) heating for annealing purposes or normalizing continuously moving metal strip and rod; (5) heating with temperature control and great uniformity very large muffle annealing furnaces; (6) extension of inductive heating with small furnaces supplied with very high frequency power for all varieties of scientific investigation where freedom from contamination of the charge is essential and where the temperatures that may be reached will meet all scientific requirements; (7) the production on a large scale of very high temperature heaters for such purposes as the graphitization of coke; (8) the construction and use of multiple ton furnace-ladles which will maintain the metal at a constant temperature and electrically stir this metal to any desired degree for refining it under slags. WHB(23)

Heating in Liquid Baths. R. L. ROLF. *Houghton's Black & White*, Vol. 3, Jan. 1931, pages 10–15.

The advantages of the salt bath as a non-scaling, non-oxidizing medium for uniform heating are discussed. The selection of a proper salt or combination of salts permits a wide range of temperatures from 300° to 1200° F. Salts should be completely water soluble so that the work will come out bright and clean from the quench. It is good practice, especially for pieces with greatly varying sections, to pre-heat the pieces before introduction into the bath to avoid cracks from the sudden temperature change. Ha(23)

A Thermal Study of an Open-Hearth Furnace. W. M. HENRY (American Steel & Wire Company) & T. J. MCLOUGHLIN (Carnegie Steel Company). *Preprint* for May 1931 meeting *American Iron & Steel Institute*, 39 pages.

Very detailed study of heat balance, pressure, draft, temperature, and volumetric relations in a 60 ton basic open hearth. The test required the services of 21 men. Data are given in 14 tables. Steel of 0.07% C, 0.36% Mn, 0.03% S, 0.01% P was made. About 7½ million B.t.u./ton were supplied as fuel and in preheating air. Nearly 3 million B.t.u./ton were discharged through the stack. Much air infiltration was met. It is suggested that the use of fans to supply the required air might lead to economies. The authors comment on the lack of standardization in methods of presenting heat balances. HWG(23)

REFRACTORIES & FURNACE MATERIALS (24)

Refractory Materials. COLIN PRESSWOOD. *Metallurgia*, Vol. 3, Apr. 1931, pages 223–225.

A discussion of laboratory methods for testing refractories. JLG(24)

Comparison of Insulating Materials for Industrial Furnaces and Boilers. (Vergleich von Wärmeschutzstoffen für industrielle Oefen und Kessel.) VICTOR PASCHKIS. *Archiv für wärmewirtschaft und Dampfkesselwesen*, Vol. 12, Jan. 1931, pages 9–11.

Choice of insulating materials for furnaces, boilers, etc., can be somewhat simplified by approximation formulae. They are based upon derivation from known figures for the limiting case of the plate. Approximate known figures for practical purposes are given. MAB(24)

Refractory Materials for Electric Furnaces. III. Nickel and Its Alloys, Including Nickel-Chromium Alloys and Nickel-Silver. ALFRED B. SEARLE. *Metal Industry*, London, Vol. 38, June 5, 1931, pages 569–571.

The properties of many refractories are listed. Among the chief requirements for bricks for use in electric furnaces used to melt nickel are: refractoriness should not be less than that of Seger cone 32 (1700° C.), should be resistant to very sudden changes in temperature, should be poor conductors of electricity, etc. Roofs of furnaces are made of silica brick or even carborundum and alundum. Care must be exercised in the use of heat insulating brick which may cause too high a temperature of lining. PRK(24)

A Study of Magnesia Refractories. (Recherches sur les produits refractaires magnesiens.) LONGCHAMBON & KO-FUH-TSIANG. *Revue de Métallurgie*, Vol. 28, June 1931, pages 324–329.

Experiments were conducted using plant practice but starting with pure materials to determine the conditions of sintering magnesia, agglomeration of the sinter into bricks, the influence of the natural and intentionally added impurities and the changes produced by burning of brick. The density increases up to 1800° burning and then decreases. It is considerably affected by the presence of foreign elements. Addition of Al_2O_3 decreases the refractoriness of MgO bricks. Fe_2O_3 is an excellent binder at low temperatures but very rapidly reduces the softening point; even small amounts of CaO reduce cohesion very strongly so that bricks cannot be made; SiO_2 produces solid agglomerates but affects too much the softening point which is even more affected by the mixture of SiO_2 and CaO; a mixture of Fe_2O_3 with CaO is excellent as an agglomerant. The temperature of burning has a pronounced effect on the softening point which is higher the higher is the former. Pure magnesia with caustic magnesia binder after burning at 2000° was still serviceable at 1900°. JDG(24)

GASES IN METALS (25)

Gas Removal and Grain Refinement of Aluminium Alloys. W. ROSENHAIN, J. D. GROGAN & T. H. SCHOFIELD. *Engineering*, Vol. 130, Sept. 12, 1930, pages 340–341; *Foundry Trade Journal*, Vol. 43, Sept. 11, 1930, pages 177–180.

Abstract of paper read before the Institute of Metals, Sept. 10, 1930. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. LFM+VSP(25)

The Determination of Oxygen and Nitrogen in Irons and Steels by the Vacuum-Fusion Method. H. C. VACHER & LOUIS JORDAN. *Bureau of Standards Journal of Research*, Vol. 7, Research Paper No. 348, Aug. 1931, pages 375–401.

Apparatus and procedure for the determination of H, O and N in ferrous materials by the vacuum-fusion method are described in detail. The results of a number of analyses of ferrous materials are discussed. The data indicate that the method (in the absence of interferences) gives values reproducible to within 0.002% for either O or N. The data also indicate that the accuracy of the O determination is affected only when the steel contains a relatively large amount of alumina and Mn or when the fusion is made in a crucible which already contains a residue in which Mn is present. No similar influences have been encountered, which would affect the accuracy of the N determination. The oxides commonly encountered in ferrous materials, with the exception of alumina, are probably completely decomposed shortly after the sample has melted. The time of decomposition, when the sample does not contain relatively large amounts of alumina, is approximately 5 min. If the decomposition should require a longer time, the harmful effect of Mn is increasingly evident. Mn affects an O determination when it is simultaneously present as vapor with carbon monoxide immediately above the crucible. Such a condition results in the formation of a non-volatile compound, presumably manganese oxide, which deposits in the cooler parts of the furnace and, consequently, is not determinable with the present apparatus. The effect of Mn vapor has been detected from residues containing as little as 0.2% Mn. Therefore, it is recommended that analysis be made in crucibles free from Mn. A relatively slow decomposition of oxides in the presence of Mn vapor is considered to be the most serious source of error so far identified in the O determination. WAT(25)

The Absorption of Nitrogen by Steel. R. S. DEAN. *U. S. Bureau of Mines Report of Investigations* 3076, Mar. 1931, 8 pages.

The effect of N on the quality of steel is reviewed. Evidence is given that the solid solubility of N in pure iron is below 0.005% and its absorption is indicated to be due to impurities, particularly Si. It is concluded that the known effects of N in steel are such that the steel-maker will very soon be called upon to control the N content of at least part of his metal. At present there is no proved method of doing this. AHE(25)

INSPECTION (26)

The Fracture of Quenched Specimens as a Quality Test in Tool Steel. (Hardbrottsundersökning sasom kvalitetsprovningsmetod för verktygstal.) RARNAR ARPI. *Jernkontorets Annaler*, Vol. 115, Feb. 1931, pages 75–94, 42 references.

The object of the investigation was to ascertain if the fracture of specimens quenched from different temperatures gives a reliable indication of the quality of the steel. The specimens were compared with a scale of 10 fracture classes, where 0 designates a very coarse-grained fracture and 10 the finest fracture obtainable. Experiments have been carried out on different materials at several Swedish steel works. The method is very simple, and it is not difficult to classify the fractures, but on the other hand the method has not been found to be entirely reliable. While steels with a wide quenching range (fine grained fracture at widely differing quenching temperatures) also show good results when practically tested as tools, a narrow quenching range may not necessarily mean inferior quality. HCD(26)

Testing for Acceptance or Service. Correspondence from A. PORTEVIN, Paris, France. *Metal Progress*, Vol. 19, Apr. 1931, pages 87–88.

Further notes on safety in aircraft parts. WLC(26)

Methods Employed in the Testing of Cast Iron Pipe. W. C. CONARD. *Water Works Engineering*, Vol. 83, Jan. 1, 1930, page 28.

General description of the various tests to which cast iron pipes are subjected for inspection. GN+WHB(26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Manganese and Sulphur in Mild Steel. BERNARD THOMAS. *Iron & Steel Industry & British Foundryman*, Vol. 4, May 1931, pages 259–260.

Limits in the S and Mn contents of mild steel for welding and forging purposes are expressed graphically. For welding, they are 0.065% S with 0.70% Mn; for forging they are 0.10% S with 1.40% Mn. CHL(27)

Effect of Adding Bismuth to Cast Iron. E. K. SMITH & H. C. AUFDERHAAR. *Iron Age*, Vol. 128, July 9, 1931, pages 96–100.

Gives results of research conducted by the authors. Cites literature on Bi. In general, the effect of Bi on cast Fe is as a softener; strength is lowered as is the Brinell hardness number. Bi treated bar may be drilled more easily than untreated bars. Additions of Bi to most cast Fe results in softening effect coupled with breaking up of carbides. This is due to deoxidation of cast Fe. Results of the effect of Bi on malleable Fe and steel were inconclusive, due to the fact that Bi boiled at a lower temperature than malleable Fe and steel. VSP(27)

Statistical Research of the Analyses of Pig Iron. (Grosszahl-Forschungen an Roheisen-Analysen.) K. DAEVES. *Stahl und Eisen*, Vol. 51, Feb. 12, 1931, pages 202–204.

During three months, the analyses of 3 blast furnaces producing Thomas pig iron were used to plot curves of frequency for every individual element. A comparison with the analyses of the subsequent iron mixer shows the equalizing effect upon the variations of the analyses. The relations between silicon, manganese, phosphorus and sulphur were established in curves. GN(27)

Investigations on the Effect of Oxygen and Sulphur on Forgeability, Red Shortness and Other Properties of Pure Iron. (Untersuchungen über de Einfluss von Sauerstoff und Schwefel auf die Schmiedbarkeit, Rotbrüchigkeit und andere Eigenschaften des reinen Eisens.) E. W. FELL. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, pages 386–387.

This is an abstract of the original paper by the author in *Archiv für Eisenhüttenwesen*, Vol. 4, Feb. 1931, pages 393–400, as abstracted in *Metals & Alloys*, Vol. 2, Aug. 1931, page 153. GN(27)

Effect of Aluminum on the Wearing Qualities of Steel. (Einfluss des Aluminiums auf den Verscheiss von Stahlen.) R. COLLEE. *Metallbörse*, Vol. 21, Jan. 31, 1931, page 199.

The manufacturers of fire arms found that abnormal wear of the steel sometimes occurred. An exhaustive investigation of all factors was made and it was found that abnormal wear was associated with relatively high aluminum oxide content. The following method was employed to determine the aluminum oxide content: The steel was dissolved in hydrochloric acid which dissolved everything but the silicic acid and the aluminum oxide. When fusing with sodium carbonate, the alumina was converted into soluble sodium carbonate which was converted into aluminum chloride by dissolving in hydrochloric acid. The silicic acid was obtained as a residue. Sodium phosphate was added to the filtrate to form aluminum phosphate which is insoluble in acetic acid whereas iron phosphate dissolves. When adding sodium hypophosphate and sodium acetate, the iron salts are reduced completely to the hyposulphate, and aluminum is precipitated as aluminum phosphate. WHB(27)

Silicon as an Alloying Element. J. ARNOTT. *Metal Industry*, London, Vol. 38, June 12, 1931, pages 597–598; June 19, 1931, pages 616, 620; *Foundry Trade Journal*, Vol. 44, June 11, 1931, pages 397–398.

Paper presented before Institute of British Foundrymen, June 9–12, 1931. Includes discussion. Brief mention is made of iron-silicon and aluminum-silicon alloys. Silicon-bronze (Cu 94: Si 4: Zn 2) is a substitute for gun-metal. The addition of 2.8% Si to Monel metal gives an alloy hardenable by heat treatment—softened at 980° C. and hardened at 590° C. On the Metal Constituents in the Bright Gold. I. On the Heat Resisting Metals. II. On the Fastening Metal Bi. III. On the Other Metals Except Bi and Rh. AKIRA NAKATSUCHI. *Journal Society of Chemical Industry*, Japan, Vol. 34, May 1931, pages 164B–166B.

The author has an opinion that heat-resisting metals probably serve as protective colloids for gold. Gold showed no heat-resisting power at temperatures above 500° C.; there was much grain growth. The latter could be suppressed even at 768° C., Rh having the greatest preventive action.

Part 2. Bi is added as a flux; Au is dispersed in a colloidal form into the melted mixture of glaze and Bi_2O_3; if Rh is present, grain growth is prevented and the metal film is fastened on the ware completely with brilliancy.

Part 3. The addition of Cr, Al, Fe and Ru prevents grain growth in gold, and makes a brilliant golden film attainable in burning. Cr may probably serve to prevent grain growth up to 650°, Rh being used for higher temperatures. MAB(27)

The Influence of Molybdenum and Titanium on the Properties of Gray Cast Iron. (Ein Beitrag zur Frage des Einflusses von Molybdän und Titan auf die Eigenschaften von Grauguss.) J. H. KÜSTER & C. PFANNENSCHMIDT. *Die Giesserei*, Vol. 18, Jan. 16, 1931, pages 53–58.

The influence of Mo (0.5–2.5%) and Ti (0.05–0.2%) on the mechanical and structural properties of gray cast Fe is investigated. With increasing Mo addition to gray cast Fe the tensile, the continuous impact and the bending strengths and the Brinell hardness of the Fe increases. Metallographic tests show that Mo tends to promote the carbide formation. The cast Fe samples alloyed with Ti in every case show an increased resistance to wear. With increase in the Ti addition the tensile and bending strength of the cast Fe increases. Micrographs (16) are shown. (27)

The Influence of Nickel on the Temperature of the Metastable and Stable A_1 Conversion of Eutectic Iron-Carbon and Iron-Carbon-Silicon Alloys. A Contribution to the Question of the Graphite Eutectoid. (Der Einfluss von Nickel auf die Temperaturen der metastablien und stabilen A_1-Umwandlung eutektischer Eisen-Kohlenstoff- und Eisen-Kohlenstoff-Silizium-Legierungen. Ein Beitrag zur Frage des Graphiteutektoids.) A. MERZ & F. FLEISCHER. *Die Giesserei*, Vol. 17, Aug. 22, 1930, pages 817–825.

The dependence of the conversion temperature on the velocity of the test is linear. For each 1% Ni, the metastable conversion temperatures are reduced by 12° C. Si increases the temperature slightly but becomes more pronounced for more than 2% Ni. The hysteresis increases with increasing contents of Ni and Si. After proper heat treatment in order to obtain the stable state, the investigations showed a linear increase of the A_1 conversion temperatures of 31° C. for each 1% Si and linear reduction of 12% for each 1% Ni. The existence of a graphite eutectoid is affirmed. Test curves and micrographs are given; and 14 references cited. Ha(27)

INSTRUMENTS & CONTROLLERS (28)

New "Standard" Temperatures. (Neue temperaturfixpunkte.) OTTO REDLICH & GUSTAV LÖFFLER. *Zeitschrift für Elektrochemie und angewandte physikalische Chemie*, Vol. 36, Sept. 1930, pages 716–722.

The new method of measuring temperatures by means of the platinum resistance thermometer and Kohlrausch-Jaeger differential method of overlapping shunts is discussed. The transformation points of the solid phases $NaNO_3$, $Na_2SO_4.10H_2O$ (Glauber's salt), $NaNO_3$, Na_2SO_4, H_2O (Darapscite) and Na_2SO_4, $Na_2SO_4.10H_2O$, NaCl are given as 13.154° C. and 17.878° C respectively, the former with a mean error of 0.0011° C., the latter with a mean error of 0.0022° C. The eutectic temperature for the potassium chloride-ice system is given as −10.646° C. with a mean error of 0.0025° C. OWE(28)

Magnetization and Magnetic Aging of Permanent Magnets for Electrical Measuring Instruments. (Magnetisierung und magnetische Alterung von Dauermagneten.) E. SCHRAMKOW & B. JANOWSKY. *Zeitschrift für technische Physik*, Vol. 11, Oct. 1930, pages 361–363.

Problems involved in the utilization of permanent magnets for measuring instruments. (28)

Study on Thermostat. III. Research on Time Lag of Various Thermometers. SHUU KAMBARA & MOTOTARO MATSUI. *Journal Society of Chemical Industry*, Japan, Vol. 34, May 1931, pages 167B–172B.

Explanation of time lag and previous method of determination, the principle of the new method of determining lag, the apparatus and experimental procedure, observations and results, and a summarizing statement and table constitute the treatment of the subject. MAB(28)

Examination of Zeiss' Large Metallurgical Microscope. (Prövning af Zeiss' stora metallmicroskop.) C. BENEDICKS & P. SEDERHOLM. *Jernkontorets Annaler*, Vol. 115, June 1931, pages 302–309.

The stability of the instrument was found excellent, a shaking through a 10° angle producing only 0.001 mm. displacement of the field. The fine adjustment is slightly too gross, for a magnification of 1500, but a further refinement in the set screw enables a magnification of 3000 to be precisely attained. A sector diaphragm constructed by one of the authors was found to be superior to the eccentric diaphragm for oblique illumination provided with the instrument. HCD(28)

Optical Activity and High Temperature Measurements. F. M. JAEGER. McGraw-Hill Book Company, Inc., New York, 1930. Cloth, 6 × 9¼ inches, 450 pages, 137 figures. Price $4.00.

This book is essentially a reprint of the lectures delivered by Professor F. M. Jaeger of the University of Gröningen, at Cornell University, during the second semester of 1928–29, under the George Fisher Baker Non-Resident Lectureship in Chemistry.

It is the custom to introduce these annual lectures by a lecture devoted to some topic of general interest which in this case is a discussion of the present and future state of our natural resources. A brief account is given of the energetic and material resources of nature, the former being represented by the natural stores of energy that can be utilized directly for the production of mechanical force, and the latter being represented by minerals and metals. There are three series of lectures. The first is concerned with spatial arrangements of atomic systems and optical activity; the second with the methods, results and problems of precise measurement at high temperature; and the third with the constitution and structure of ultramarine. For the most part the investigations preceding the lectures were carried out by Professor Jaeger and his co-workers in the chemical laboratory of the University of Gröningen.

The first series give a general discussion of our more recently acquired views on the relations between geometrical and physico-chemical properties of atomic systems occurring in inorganic and organic molecules. After a brief review of the discovery of the facts summed up in Pasteur's Law, the author illustrates how the principle of symmetry can be utilized in problems dealing with the possibility of separating optically inactive substances into their enantiomorphous antipodes. The historical role of Le Bel Van't Hoff is emphasized. Theoretical views are given on the chemical structure of complex inorganic salts and the basis on which our ideas of their spatial arrangement is founded. The possibility of effecting a totally asymmetrical photosynthesis is discussed with emphasis on the significance of this problem in the synthetic processes of nature.

The second series first takes up the principles and problems involved in high temperature measurements up to 1650° C. which is of extreme importance in the ceramic, glass and metallurgical industries. After discussing the development and refinements of the measuring methods at high temperatures and some of their applications the author says on page 249, "It would be interesting, at this date, to reinvestigate a number of phenomena of binary and ternary metallic systems, applying the modern improved methods. This might develop many new and surprising facts and phase-transitions which so far have escaped observation by the cruder methods heretofore employed. Such work might prove to be of the greatest importance for the metallurgical industries also." The methods and equipment for the accurate determination of the temperature coefficient of the surface tension of liquids between −80° and +1625° C. is especially interesting. The methods, equipment and results at high temperatures are given for specific gravity and viscosity determinations, the measurement of the electrical conductivity of molten salts which is especially difficult above 700° C. and the measurement of the internal friction of molten salts. On the important topic of the precise measurement of the specific heat of solids up to 1650° C. many practical points are discussed and considerable data is included.

The third series is a discussion of the constitution and structure of ultramarine and gives the results of investigations recently carried out at the University of Gröningen.

The contents of this book should prove of inspirational and material value to students of physics and chemistry at large and the second series of lectures should be of particular interest to those metallurgists who are interested in fundamental research. The author's easy style, versatility, natural familiarity with the work which he has directed and inclusion of many data tables made the book valuable for general information and reference.—

Measurement of Surface Temperatures. (Mätning av yttemperaturer.) ARVID JOHANNSEN. *Jernkontorets Annaler*, Vol. 115, May 1931, pages 278–281.

The apparatus consists of a box-like arrangement with the open edge fitting the contour of the surface to be measured. A mercury thermometer is placed alongside the hot surface and pressed against it by asbestos or cotton packing held in the box. Temperature equilibrium is attained in about 20–30 minutes. On an iron surface the arrangement may be held in place by a magnet. HCD(28)

Taking Industry's Temperature. D. C. LAMB. *Scovill Standard*, Vol. 4, May-June 1931, pages 8–9.

Some of the methods and instruments for temperature measurements are outlined briefly. Ha(28)

How to Make Thermo-Elements of Thin Wires. (Herstellung von Thermo-elementen aus dünnen Drähten.) O. KANTOROWICS & R. REINECHE. *Zeitschrift für technische Physik*, Vol. 12, Dec. 1930, page 547.

Hot junction of 0.02 mm. wires were cold welded by using goldfoil. EF(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Experience with Stay-bolts and Fire-box Copper in England and Germany. (Erfahrungen mit Stehbolzen- und Feuerbuchskupfer in England und Deutschland). R. KÜHNEL. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 1–11.

Includes discussion. The results on corrosive effects lead to 3 conclusions: (1) the influence of temperatures above 400° C. is greater than that of changes in gas atmosphere, CO_2, CO or O_2; (2) the influence of HCl and SO_2 is greater than changes in gas atmosphere and exceeds it at 400° with 0.1% HCl 65 fold, 0.1% SO_2 is $^1/_3$ as effective as an equal amount of HCl; (3) water from leaks catalyzes the corrosion. EF+RFM(29)

Effect of Low Temperatures on Metals and Alloys. H. W. RUSSELL. *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Metals, June 1931 meeting *American Society for Testing Materials*, pages 486–506.

Low temperature properties are important in refrigerating engineering, in railways and in aircraft. Refrigerating agents that may be used in testing are listed, and low temperature thermometry discussed. Data on mechanical and physical properties at low temperatures of metals and alloys are tabulated. Tensile strength and hardness increase. Impact resistance usually decreases. Brittleness, on notched specimens, is the main low temperature trouble. Unnotched samples are less likely to be brittle. Aluminum and its alloys do not become very brittle but most ferritic steels do. Nickel steels, especially those with high nickel, are quite free from brittleness. Hitherto unpublished work on endurance at −40° F. is reported on Monel, plain Cr stainless, 18–8, $3^1/_2$% Ni steel and Cr Mo steel. All endurance limits were higher than at room temperature, approximately following the increase in tensile strength. All retained good notch toughness even at lower temperatures save the plain Cr stainless (0.07% C, 13.85% Cr). Cast iron is not appreciably injured at low temperatures, even brittleness not being greatly increased. Failures are more likely due to stresses arising from temperature changes than from poorer properties of the cast iron itself. Elastic properties, thermal expansion, heat capacities, thermal conductivity, electrical conductivity and other physical properties are discussed. In general increases are found in all properties save toughness (elongation, reduction of area, impact resistance) and in compressibility, thermal expansion and specific heat, which decrease. HWG(29)

Apparatus for Low-Temperature Endurance Testing. H. W. RUSSELL & W. A. WELCKER, JR. Appendix III to Report of Joint Research Committee on Effect of Temperature on the Properties, *Preprint* No. 29, June 1931 meeting, *American Society for Testing Materials*, 7 pages.

Describes method for making endurance tests at −40° C. on an R. R. Moore endurance machine by boxing in specimen and bearings and cooling with solid CO_2. Automatic temperature control is described and temperature uniformity of specimen is discussed. Kerosene is a good lubricant for the endurance machine at −40° C. Methods for low temperature tensile, Brinell and impact testing are briefly discussed. Low temperature endurance and other data obtained with the apparatus described are included in another paper by Russell at the same meeting. It costs about $2.00 per million cycles, operating at the 1750 r.p.m. for solid CO_2 to cool the endurance apparatus to −40° C. Hence a single test run to 50 million cycles costs $100.00 for refrigerant alone. HWG(29)

Endurance and Other Properties at Low Temperature of Some Alloys for Aircraft Use. H. W. RUSSELL & W. A. WELCKER, JR. *Technical Note* No. 381, *National Advisory Committee for Aeronautics*, June 1931, 13 pages.

Streamline wire fails by corrosion-fatigue in aircraft service. Corrosion resistant materials like 18–8 are far better under corrosion fatigue than ordinary steel. Their properties at low temperatures, however, have to be considered for aircraft service. Low temperature endurance, tensile, impact and hardness data were therefore obtained. 18–8 in annealed and hard-drawn condition, Monel, 12% Cr stainless, as well as a $3^1/_2$% Ni steel and a Cr Mo steel were studied. The last two have not been suggested for streamline wire, but find other wide use in aircraft. An R. R. Moore endurance machine was enclosed so that bearings and specimen were cooled to −40° C. by "dry ice," with automatic temperature control. Details of the apparatus are given. Tensile and endurance tests were made at −40° C., impact and hardness at several temperatures, down to about −80° C. Tensile strength, hardness and endurance limit all increased at −40° C. Except in annealed 18–8, ductility was only slightly affected, usually increasing, but notched-bar impact strength fell off. However, only one alloy, the plain Cr stainless, became really brittle at low temperatures, that one becoming extremely brittle at −40° C. or below, the others remaining decidedly tough at −60° C. or below. HWG(29)

Alloys of Iron, Manganese and Carbon. Part 1. Preparation of Alloys. FRANCIS M. WALTERS. **Part 2. Thermal Analysis of the Binary Alloys.** F. M. WALTERS & CYRIL WELLS. **Part 3. X-Ray Study of the Binary Alloys.** M. GENSAMER, JOHN F. ECKEL & F. M. WALTERS. **Part 4. A Dilatometric Study of the Binary Alloys.** F. M. WALTERS & M. GENSAMER. *Preprint American Society for Steel Treating*, Sept. 1931, 45 pages.

The materials used in the preparation of the alloys were distilled Mn and electrolytic Fe melted in a vacuo. The alloys were melted in an induction furnace under argon at atmospheric pressure, because of the high vapor pressure of manganese. Commercial argon was purified by passing over red-hot metallic calcium and cooper oxide, and through absorbents for water and CO_2 The melts were allowed to freeze in the furnace. The crucibles were c. p. magnesium oxide and were fired in an induction furnace. The melts, if not overheated, lost little Mn. Over twenty melts with C 0.02% or less have been made for 0 to 100% Mn, and about 20 more have been made with various percentages of C up to 1.65%. A gradient furnace with certain novel features was used for the thermal analysis of high purity, Fe-Mn alloys containing from 0 to 60% Mn. In general, the results agree with those of previous investigators. The low temperature transformations, however, were found definitely in 13 to 20% Mn alloys on both heating and cooling, and it was established by thermal analysis that the α to γ transformation in the 13% alloy takes place about 600° C. (1110° F.). The dilatometer constructed for the study of the Fe-Mn alloys can be used from −200 to +1000° C. with the specimen in a vacuum or an inert gas. The indications of phase changes observed by thermal analysis have been confirmed and extended. The low temperature transformations on cooling of the alloys with 13% or more Mn may be ascribed to the epsilon phase. X-ray measurements of lattice dimensions are used in the interpretation of the dilatometric observations. A preliminary study of the rate of heating and cooling indicates that the rate makes little difference in the temperature at which the transformation begins, but has a marked effect in the transformation range. WAT(29)

Study of the Diffusion of Carbon Monoxide through Steel in the Neighborhood of 800° and 1000°. I (Première contribution a l'étude de la diffusion de l'oxyde de carbone a travers l'acier aux environs de 800° et de 1000°). CLAUDE DECROLY. *Chimie & Industrie*, Vol. 25, Special Number, Mar. 1931, pages 484–489.

Experiments carried out using a slight modification of Thorburn's technic for the determination of CO showed that, at atmospheric pressure, CO does not diffuse through a steel tube 3.5 mm. thick at 800° nor at 1000° C. WHB(29)

The Thermal Conductivity of Cast Iron Between 0 and 100 Degrees Centigrade. H. THYSSEN, J. R. MARECHAL & P. LENAERTS. *Foundry Trade Journal*, Vol. 44, June 11, 1931, pages 405–407.

The authors after passing in review the theoretical principles of heat transmission describe a modified Despretz method of determining relative conductivities. A series of commercial cast irons were tested, using bars of increasing diameters. The main features are that conductivity is higher with increasing phosphorus content and with diminishing diameters of bars. It is also postulated that the size of the graphite lamellae is proportionate to the diameter of the bars. A commercial inference is drawn in connection with the phosphorus content of economizer castings, while pointers are given for the choice of cast iron of high conductivity for industrial applications. The apparatus used is described in detail, mathematical equations set forth the theoretical principles, and the results are illustrated by curves and graphs. WAT+OWE(29)

Creep of Metals. H. J. TAPSELL. Oxford University Press, New York, 1931. Cloth, $6^1/_4 \times 10$ inches, 285 pages. Price $12.00.

Only a man with much experience in the high temperature testing of metals, and with a judicial temperament, could have written this book. It is one that needed to be written, and written the way Tapsell has done it.

He has patiently and impartially studied the work of all the investigators in this line, with detailed attention to their test methods, and put the results all together. He has not cast aside the early work, done with relatively crude methods, but takes from it such facts as it clearly proves, while declining to accept conclusions not warranted by the accuracy of the data upon which they are based. He gives as much credence to the results of careful work by others as he does to his own, a rare quality in an author.

The chapter headings are: short time high temperature tests; general effects of overstrain and creep; characteristics of normal creep curves; short-time creep test methods; long-time creep test methods; the limiting creep stress; creep limits from short-time creep tests; stress limits based on a specified total creep within a given period; stress limits for absence of creep; modifying influences on creep; creep in relation to some other mechanical properties; creep properties of ferrous materials; creep properties of non-ferrous materials; design stresses.

Tapsell says "There can be no doubt that long-time creep tests at present offer the only reliable means of determining the true creep characteristics of materials under service conditions. A prior knowledge of the long-time creep properties of a particular material or class of materials appears essential to the development of a shortened creep test method."

The survey of testing apparatus and methods for determining high temperature properties, the collection of data from many sources, so annotated that its probable reliability is evident, and the engineering discussion of how the data may be applied to design will be of real value to metallurgists and engineers concerned with metals for high temperature use.—
H. W. Gillett(29)-B-

New Metallurgical Research and Its Relation to Shipbuilding. (Neuere metallurgische Forschungen und ihre Beziehungen zum Schiffbau.) A. POMP. *Stahl und Eisen*, Vol. 51, Mar. 19, 1931, pages 368–369.

An article by S. L. Archbutt, in *Transactions of the Institute of Marine Engineers*, Vol. 42, 1930, pages 295–346, is reviewed. This article deals in particular with the hot tensile strength of the steels used in shipbuilding. GN(29)

Corrosion and Other Problems in the Use of Metals at High Temperatures in the Chemical Industries. F. H. RHODES. *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 meeting *American Society for Testing Materials*, pages 42–50.

In distinction from many other high temperature uses for metals, the majority of chemical uses are at such low temperatures that creep is of no importance and corrosion resistance is the main need. A few higher temperature uses are discussed. Retorts for reburning bone char in sugar refineries may operate at 1470° F. Cast iron warps and oxidizes. Steel of 0.75–1% C, 22–25% Cr stands up. Heat exchangers in contact H_2SO_4 plants are made of cold drawn seamless carbon steel tubing, but they corrode if the gas is not dry. Cr steel is better but expensive. Coolers for raw burner gas are of cast iron at the hot end, lead at the cool end. There is attack at the junction, with no satisfactory solution for the problem. Attack by HCl is a problem. Fe-Ni-Mo alloys resist at low temperatures but are attacked at high, and do not have suitable properties for high pressure autoclaves. Embrittlement of steel occurs in evaporators for concentrating NaOH. Fusion pots for caustic operating at 1100° F. are of cast iron. A stronger, less brittle material is needed. Better materials are needed for phenol pots. Steel tube stills for coal tar at 400–500° F. are attacked. Cast iron resists better and is used for the part in that temperature range. Condensers are cast iron, Admiralty metal, nickel or Monel, but the materials are not wholly satisfactory. Tar acids attack steel condensers. Tin suitably supported, is used. Ni steel and the special Ni-Cr steels resist and do not discolor the distillate but have not been generally adopted. Hydrogen attack in high-temperature, high-pressure ammonia synthesis causes decrease in strength of containers. A nitride film hinders diffusion of hydrogen and a 0.30 C, 2.25 Cr steel, which can form a nitride film, is suitable. HWG(29)

Bursting Stress in High Pressure Piping: Fundamental Formulas of Design. HARVEY A. WAGNER. *Heating, Piping & Air Conditioning*, Vol. 3, 1931, pages 658–661.

The article is a discussion of the article, "Higher Pressures and Temperatures as They Affect the Design, Installation and Maintenance of Piping" by J. J. Harmon, Dec. 1930, *Heating, Piping and Air Conditioning*, page 985, with author's reply. When theoretically correct results are desired, it is the writers belief that Clavarino's formula should be used for designing piping, where closed end conditions prevail. This article compares the Birnie and Clavarino formulas and shows their differences in application. The author believes that the article is a helpful contribution to piping engineers as it discusses the fundamentals of design clearly. WAT(29)

The Thermal Expansion of Some Alloys of the System; Nickel-Iron, and the Effect of Heat Treatment. H. HIEMENZ. *Festschrift zum 70. Geburtstag von Wilhelm Heraeus*, 1930, pages 69–79.

By the proper selection of composition, almost any coefficient of expansion can be obtained with the Ni-Fe alloys. Of especial interest are the following alloys: invar, 36% Ni and 64% Fe, expansion between 0° and 100° C. almost 0 (used in the watch industry); 50% Ni and 50% Fe, for air-tight melting into glass, expansion about the same as that of Pt; alloys with 42–46% Ni, whose low expansion is compensated with a Cu case, used in the manufacture of incandescent lamps. Alloys with 25% Ni have a high expansion. The alloys all exhibit irregularities in their thermal expansion, which is represented in tabular and graphic form. By means of proper heat treatment it can be changed as much as 20%. These sometimes undesirable anomalies occur, for example, in combinations of a 36% Ni alloy with a 22–27% Ni-Fe underneath. On alloying 5% Mo with the 22–27% Ni-Fe, the expansion anomaly is suppressed and the thermal expansion increases 50%. The other alloys can likewise be improved by alloying with 5% Mo, so that the difference between the thermal coefficient of expansion at room temperature and at 100° is only 2–3%. WAT(29)

The Dependence of the Critical Shearing Stress of Cadmium Crystals on Temperature. (Ueber die Temperaturabhängigkeit der kritischen Schubspannung von Kadmiumkristallen.) W. Boas & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalt*, Sonderheft 10, 1930, pages 122–130.

The beginning of plastic elongation of cadmium crystals over the range from 20° K. to the melting point is investigated. The critical shearing stress of the transition system decreases at first linearly with increasing temperature and remains constant from about 140° below the melting point up to it. The results are given in diagrams and photographs. 14 references. Ha(29)

Scaling of Steel at Elevated Temperatures by Reaction with Gases and the Properties of the Resulting Oxides. D. W. Murphy, W. P. Wood & W. E. Jominy. *Preprint, American Society for Steel Treating*, Sept. 1931, 35 pages.

This paper presents the result of an investigation of the variables affecting the oxidation of steel in the temperature range 1095 to 1316° C. (2000–2400° F.) and shows that the effect of complex atmospheres on steel may be predicted from a knowledge of the equilibria in the systems Fe–O–C and Fe–O–H. The results of this study may be summarized as follows: The loss in weight of the metal due to scaling is proportional within limits to the area of the sample. The effect of increasing the carbon in the range 0.3 to 1.1% decreases the scaling losses. The scaling loss is lessened by a slow rate of the flow of gas. The rate of oxidation decreases as the time of exposure increases. The extent of oxidation is dependent on the relative rates of diffusion of the gases concerned in the reaction. A new method has been applied to the determination of equilibria in the reactions, $FeO + H_2 \leftrightarrows Fe + H_2O$ and $FeO + CO \leftrightarrows Fe + CO_2$ in the temperature range of 1093 to 1427° C. (2000–2600° F.). The melting point of ferrous oxide was determined from data on the two systems at 1360 ± 10° C. (2480 ± 18° F.). The heat of fusion of ferrous oxide was calculated as 28,000 calories per gram mol ± 5000 calories. X-ray data have shown that ferrous oxide is stable above its melting point having a constant 4.289 A. U. both above and below the melting point. No evidence of extensive solutions of Fe or Fe_3O_4 in FeO was obtained in this investigation. The scaling or non-scaling action of a gas atmosphere containing nitrogen, carbon dioxide, carbon monoxide, hydrogen and water vapor may be predicted with considerable accuracy for a number of steels on the basis of the equilibrium ratios derived for the two systems Fe–FeO–CO–CO_2 and Fe–FeO–H_2–H_2O. WAT(29)

The Question of Plasticity. Deformation at Low Temperatures. (Zur Frage der Plastizität. Verformung bei tiefen Temperaturen.) M. Polyanyi & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 101–104.

Three kinds of plasticity are distinguished: (1) Athermal plasticity: Occurs in crystals, i. e., zinc and cadmium-monocrystals. They possess a low elongation limit which at low temperatures becomes independent of loading velocity and temperature. After exceeding this limit, the elongation curve shows considerable strengthening. An explanation for the athermal plasticity can not be given. (2) Thermal plasticity (determined by heat treatment). It is characteristic for amorphous bodies. This type of deformation is a flowing: to each tension belongs a definite deformation velocity. This flow depends on the temperature and ceases at absolute zero. At this point, amorphous bodies can not be deformed with tensions below the theoretical shearing strength. (3) Athermal plasticity with superimposed (thermal) de-strengthening. If the range of lowest temperatures is left the thermal de-strengthening (recovery) superimposes itself on the athermal deformation and strengthening so that the deformation of strengthened crystals possesses a flow which is dependent on temperature. This kind of deformation is the one which is usually observed on multi-crystalline metal samples. The higher the temperature and the more the latter approaches the melting point the more the deformation velocity increases with the tension. 15 references are cited. Ha(29)

On the Mechanical Properties of Two Heat-Resisting Alloys. Y. Matsunaga. *Kinzoku no Kenkyu*, June 1931, pages 340–349.

The mechanical properties of two heat-resisting alloys, No. 1 (20% Cr, 80% Ni) and No. 2 (18% Cr, 12% Fe, 70% Ni) were studied. The tensile strength of these alloys increased from 70 to 110 kg/mm.² and the elongation decreased from 30 to 2% as the reduction percentage increase from 0 to 47% by cold working. The alloys heated at 100° to 200° C. show the increase of tensile strength by 5 to 10% and the decrease of elongation by about 1%. At 400° to 500° C. or higher temperatures these alloys were softened and the tensile strength decreased and the elongation increased. The temperature at which the softening takes place varies according to the composition, as well as the degree of the cold working. KT(29)

Some Alloys for Use at High Temperatures. Complex Iron-Nickel-Chromium Alloys. Part 3. The Effect of Composition and Exposure to High Temperatures. C. H. M. Jenkins & H. J. Tapsell. *Iron & Steel Institute, Advance Copy* No. 10, May 1931, 29 pages.

The effect of the addition of C and Si on the high temperature properties of alloys containing 30% Ni, 30% Cr, 4% W and Fe was studied. The tensile strengths at elevated temperatures (mainly 800° C.), the ability to withstand loads at these temperatures, and the changes in hardness produced by prolonged heatings at 800° C. were determined. The alloys with the highest strength at high temperatures contained 1.5% C. and 1% Si. An alloy of this composition hardens on being maintained at a temperature of 800° C., and microscopic examination indicated that such hardening was the result of precipitation. Alloys containing no W did not harden in this manner, and their strength at high temperatures is low. The most suitable alloys for stress resistance appear to be those which maintain, after the initial period, a fairly constant Brinell hardness when exposed to a high temperature. Contains 4 references. JLG(29)

Creep of Ultra Light Alloys under Static Loads. (La deformabilita sotto carichi statici delle leghe ultra-leggere.) N. Parravano & G. Guzzoni. *La Metallurgia Italiana*, Vol. 23, June 1931, pages 475–484.

Former data by these authors at room temperature on creep of light alloys under loads above the proportional limits (See "Static Properties of Ultra-Light Alloys," *Metals & Alloys*, Vol. 1, Aug. 1930, page 689) are examined to see what results the accelerated methods of Pomp (Extrapolation from the average rate of creep in the 50th to the 100th hour) will give when applied to them. The examination leads to the conclusion that the Pomp method gives erroneous and absurd results. If the data are taken from the 300th to the 400th hour, the error is less, but still too great. The light alloys at room temperature seem to give parabolic curves between rate of flow and time under stress. If three or four figures for rate of flow are available at sufficiently long periods of flow so that the curve is really established, plotting log of elongation against log time in hours should make possible straight line extrapolation to longer periods if the function is a logarithmic one. But data of Parravano and Guzzoni thus plotted for one 92½% Mg, 6⅔ Al, ½% Zn, ⅓% Mn alloy show straight line curve for the higher loads, e. g., those giving an elongation of 0.95% in 100 hrs., or above, but for a lower load giving an elongation of 0.015% in 100 hrs. the curve is not straight, log elongation tending to flatten out when plotted against log time. If data for the same alloy and loads be plotted as the log of the average hourly rate of flow between the 50th and 100th hour against log of load, the curve is a straight line and the tendency for cessation of flow is not shown. Whatever may be the case for steel at elevated temperatures, duralumin loaded at room temperature so that creep occurs, must be tested at least 100 hours and magnesium alloys 200 hours or more before extrapolation of any sort can be used even for a rough indication. HWG(29)

High-Temperature Metals for the Power Plant. E. W. Spring. *Iron Age*, Vol. 127, Mar. 26, 1931, pages 1004–1008; **Alloy Steels and Alloys for High-Temperature Service.** *Iron Age*, Vol. 127, Apr. 2, 1931, pages 1090–1093. **Prospects Hopeful on Metals for 1000–1500 Degrees.** *Electrical World*, Vol. 97, Mar. 7, 1931, pages 459–461.

From a paper read before the Western Power Congress at Chicago. Demand for steels that will stand up under higher working temperatures and pressures that have increased. Temperatures have increased from 750° to 1000° with 1500° F. under consideration. Pressures have increased from 600 lbs./in.² with 2500 lbs. in view. This is true of steam power plants and the oil industry. Tests show that above strain hardening temperature there is no creep limit, creep constantly going on, more rapidly with higher temperatures and increased stress. Large grain sized material has greater resistance to creep than material with reduced grain size. Forged steel with its smaller grain and higher ductility is not as stiff as cast steel. For short time high-temperature tests at 1000° F. the tensile strength and yield point are about 30,000 and 15,000 lbs./in.² respectively. Includes tables giving short-time tests on cast steel specimens previously tested in flow. Concluding portion of address discusses use of austenitic alloy steels, pointing out their advantages and disadvantages. Seating metals used are brass, monel metal, Ni alloys, rustless steel and some harder alloys, depending on the service desired. Nitralloy, a comparatively new seating metal has appeared. Total amount of deformation due to creep which can be tolerated in turbine parts should not exceed 0.2% in 20 years. Metallurgists and steel makers will meet new high-temperature and pressure demands. VSP+WHB(29)

The Graphitization of Steels at Low Temperature. (La graphitisation des aciers à basse température.) A. Portevin & P. Chevenard. *Comptes Rendus*, Vol. 193, July 20, 1931, pages 169–171.

The authors express surprise that during the course of their investigations on the tempering of quenched and "hyperquenched" steels, they discovered graphitization of a steel containing 1.6% C, 0.28% Si and 0.16% Mn. The phenomenon was brought to light owing to the extreme sensibility of the dilatometric method of investigating steel. The article is accompanied by 2 figs. upon which the findings of the authors concerning the graphitization of steels at low temperatures were based. They conclude that they have been able to transform a steel practically free from Si into the state iron-graphite by heating at temperatures below A_1. This had never been accomplished hitherto. OWE(29)

Behavior of Some Irons and Steels under Impact at Low Temperatures. Robert Sergeson. *Preprint, American Society for Steel Treating*, Sept. 1931, 16 pages.

This paper gives the results of testing, under impact, certain irons and steels at temperatures between −100 and +300° F. Properly treated nickel-molybdenum (0.15% C) S. A. E. 2115 and 2% nickel iron show excellent notched impact resistance at sub zero temperatures. Wrought iron and carbon-manganese steel show a marked falling off in notched impact resistance as 0° F. is approached. Unnotched carburized and hardened specimens of various carburizing grades when tested under impact show that the 5% and 3½% Ni steels and the 2% Ni iron possess superior qualities, especially at the sub-zero temperatures. Of the various spring steels, namely; C, C-Si, Cr, Cr-Va, Si-Mn, Cr-Ni-Mo, Ni-Mo and Ni-Si, the latter two show the highest impact resistance throughout the temperature range examined. The C steels showed the lowest. Of the stainless irons studied, the KA2 showed excellent impact resistance even to −100° F. The type AA shows a decided brittleness until temperature is raised to 350° F. at which temperature toughness is gained. The type S lies in between the KA2 and AA. WAT(29)

Metal Creep at High Temperatures. P. G. McVetty. *Machine Design*, Vol. 3, Apr. 1931, page 55.

Beside the observation of other stresses in metals, the author calls attention to the metal creep which is defined as the plastic deformation or permanent set which results from continued application of stress at elevated temperatures. See also "Creep of Metals at Elevated Temperatures," *Metals & Alloys*, Vol. 2, Aug. 1931, page 154. Ha(29)

On Some Mechanical Properties of Steel at High Temperature. K. Sasagawa. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy*, part 2, pages 199–221.

In English. An Izod specimen is heated in place and the electric furnace taken away by mechanical means, so that the specimen is broken in 2/5 sec. after removal of the furnace. Impact data are given on annealed carbon steels of 0.11, 0.23, 0.50, 0.63, 0.86 and 1.20% C at temperatures from 20° to 1000° C. The curves all show minima about 600° C. Tensile impact data are given for 0.11% C, 20 to 700° C.; 0.50% C, 20 to 900° C.; 0.86% C, 20 to 850° C.; 0.25% C, 3.7% Ni, 0.71% Cr sorbitic, 20 to 800° C.; and 0.39% C, 9.0% Ni, 16.6% Cr, austenitic, 20 to 800° C. Data are given in tables and curves. Tensile impact, short-time tensile, and creep test figures are plotted for 0.11 and 0.50% C steels. The criterion of creep limit is not stated, but at 350° C. the creep limit of 0.11% C is shown as 45,000 lbs./in.², and that of 0.50% C as 61,000 lbs./in.² Through the strain hardening range of temperatures the tensile-impact strength is lower than the short-time tensile strength, but higher above and below that range. The creep and short-time tensile curves are parallel from 350° C. to 700° C. HWG(29)

Properties of Cast Steels at High Temperatures. (Les propriétés de resistance de l'acier coule aux températures élevés.) A. Pomp. *Technique Moderne*, Vol. 21, Dec. 1, 1929, pages 766–768.

Study of a series of steels including Ni-bearing steels (Ni = 1.05, Cr = 0.27; Ni = 2.68, Cr = 0.18). Considers appropriate heat treatments and graphical representation of the resulting properties. WHB(29)

Thermomagnetic Phenomena in Steel. Raymond L. Sanford. *Preprint, American Society for Steel Treating*, Sept. 1931, 11 pages.

The great sensitiveness of magnetic properties to changes in the condition of ferromagnetic materials affords the basis of a research method by which phenomena associated with the thermal treatment of such materials can be observed, some of which are beyond the scope of other methods. This method has been called thermomagnetic analysis. In order to apply the methods of thermomagnetic analysis properly and to interpret the results with accuracy, a knowledge of the fundamental phenomena is required. The general effect of heating is to increase the magnetic permeability in the lower part of the magnetization curve and to decrease it in the upper part. The phenomena under relatively low magnetizing forces are complex and difficult to interpret because of the mutually opposing effects of various influences. These confusing effects are much less at higher magnetizations and it is possible to draw valid conclusions from results obtained in the higher range of magnetization. There are two types of magnetic change to be observed upon heating or cooling, one of which is a function solely of temperature while the other depends upon both temperature and time. The first type probably does not represent an allotropic transformation. The second type may indicate an allotropic change but not necessarily. Stress release, chemical combination or decomposition and the like may require time for their completion and should not be confused with allotropic changes. For the full development of the possibilities of thermomagnetic analysis it will be necessary to carry out much more research of a fundamental nature. Time and effort spent in this fascinating field of investigation should be amply justified, however, for it bids fair to yield results of considerable practical and theoretical value, which can be obtained in no other way. WAT(29)

LEACHING (30)

Preliminary Tests on Treatment of Titaniferous Magnetite from Mine Centre for Recovery of Iron, Titanium and Vanadium. R. J. TRAILL, W. R. MCCLELLAND & J. D. JOHNSTON. *Canada Department of Mines, Mines Branch Report* No. 720, 1931, pages 178–185.

A titaniferous magnetite from Mine Centre, Ontario, analyzed Fe 48.38%, TiO_2 12.82%, V_2O_5 0.86% and SiO_2 6.40%. 95% metallization of the Fe was readily achieved in an electric furnace (about 1000° C.) without rabbling. The magnetic concentrate analyzed Fe 61.21%, metallic iron 58.34%, TiO_2 17.61% and V_2O_5 1.07%. Leaching with $FeCl_3$ solution dissolved 50.3% of the magnetic product (82% of the iron) in 1/2 hour, leaving a residue analyzing Fe 20.82%, TiO_2 35.33% (99% of the Ti) and V_2O_5 2.10% (97.7% of the V). The high gangue content of this residue reduces its value. Magnetic concentration prior to metallization gave a concentrate (80.8%) analyzing Fe 55.9%, TiO_2 14.2%, V_2O_5 1.0% and insoluble 4.06% (10.50% in the ore). Crushing and retreating resulted in total losses in the tailing of approximately 5% of the V, 10% of the Ti, and 8% of the Fe. V is recovered (75%) from the leach residue by roasting with NaCl + $NaHCO_3$ and precipitating with Fe or Ca salts. Ti can be recovered by the sulphate process. AHE(30)

The Separation of Copper from Molybdenum in Molybdenite Concentrates by Hydrometallurgical Methods. R. J. TRAILL. *Canada Department of Mines, Mines Branch Reports* No. 720, 1931, page 186–187.

An ore containing chalcopyrite and molybdenite in a siliceous gangue and assaying Cu 4.6% and Mo 2.8% gave a recovery of 72% of the Mo by flotation in a 50% Mo concentrate carrying 3–5% Cu and 53% of the Cu in a 25% Cu concentrate. Roasting the Mo concentrate with excess S in a non-oxidizing atmosphere, followed by leaching with $FeCl_3$ gave 85% Cu extraction and left 0.5% Cu with the molybdenite. Roasting at various temperatures and leaching with soda and other solvents gave unsatisfactory results due to the sulphates formed from the alkaline earths which precipitate with the Mo as $CaSO_4$ when CaO is added to the solution to precipitate the Ca molybdate. Removal of the alkaline earths with HCl prior to roasting gave Mo recoveries of 80–90% and Cu returns of 90%. Costs are high. AHE(30)

Leaching Oxidized Copper Ores: Effect of Strength of Acid in Leaching Solvent. JOHN D. SULLIVAN & G. L. OLDRIGHT. *Report of Investigations* No. 3106, July 1931, 9 pages, *United States Bureau of Mines.*

Ajo ore leached with solutions containing 1, 2.5, 5 and 10% H_2SO_4 showed an increase of dissolution rate with increasing strength of acid. There was considerable less increase in rate for Silverbell ore. Acid consumption increased markedly as extraction progressed and was more with higher acid concentrations. It is recommended that strong acid be used for dissolving 60% of the Cu, followed by weaker solutions. Details are given. AHE(30)

Physico-Chemical Researches on Bog Ore in Japan from Metallurgical Considerations. M. KAWAGUCHI. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 99–126.

In English. Laboratory experiments of calcination, volatilization of P and S, and attempts to leach out P by caustic alkalies. HWG(30)

REDUCTION METALLURGY (31)

Smelting Secondary Aluminum and Aluminum Alloys. Pt. 10. ROBERT J. ANDERSON. *Metal Industry*, N. Y., Vol. 28, Nov. 1930, pages 514–516.

Describes equipment required in secondary Al plant, such as ladles, pouring appliances, furnace-tools and pyrometers. VSP(31)

Secondary Aluminum. R. J. ANDERSON. Sherwood Press, Inc., Cleveland, 1931. Cloth, 6 × 9 inches, 563 pages. Price $10.00.

The metallurgy, technology and economics of scrap aluminum are exhaustively treated in this book. The author has had long experience in this field, and generally speaks with definiteness. Indeed, the outspoken, positive way in which the subject matter is expressed is one of the attractive features of the book, as well as its chief drawback. Outspoken disagreement with the definition of secondary metal put forth by the Aluminum Company of America, and some of the frequent references to that firm in the discussion of economics are couched in terms that would scarcely be expected, and seem hardly necessary in a treatise that should be written from the entirely impartial and scientific, if not judicial, point of view.

The author stresses the desirability of merging the present dozen or so secondary aluminum smelters into three or four organizations, not only for economic advantages, but for the purpose of allowing larger scale operations, with larger melts and closer technical control of the operation and product.

Sorting, sampling, remelting and refining, both as to practice and equipment, the effect of impurities, and the importance of technical control are all dealt with in detail.

The comments on the use of nitrogen, chlorine, or boron chloride gas, on spectrographic analysis for impurities, and on the making of routine hot-shortness tests on secondary metal before sending it to the foundry are of especial interest.

Recurrent references to the presence of Al_2O_3 in secondary metal, and to various methods of analyses for Al_2O_3, make the reader wish that Anderson had stated which, if any, of these methods are really reliable. But this volume does not include any methods of chemical analysis.

The book is rather costly, but should be worth its price to metallurgists and foundry superintendents who have to do with secondary aluminum.

Beneficiation of Iron Ores from the Blast Furnace Viewpoint. RALPH H. SWEETSER. *Mining & Metallurgy*, Vol. 11, Sept. 1930, pages 423–426; *Rolling Mill Journal*, Vol. 4, Oct. 1930, page 546.

From paper at the Chicago meeting of the Iron & Steel Division of the American Institute of Mining & Metallurgical Engineers. Most important factor in the beneficiation of iron ores, outside of increasing iron content, is sizing. Useful work is being done by the Minnesota School of Mines and by the state of Minnesota in reference to the enrichment of ores. Extension of the life of iron ore mines depends not only on beneficiation, but also on searching out new deposits. Lake Superior ores average from 57.11% to 64.44% Fe and from 6.50% to 2.85% silica. Silica in ores is counter balanced by a corresponding decrease in the percentage of ash in coke and by progress made in the art of smelting. Includes discussion. VSP+MS(31)

New Developments in Flotation. (Neuere Ergebnisse in Flotation.) M. VAN DE PUTTE. *Metallwirtschaft*, Vol. 10, May 1, 1931, pages 349–354.

Contains 13 references. The history, development and theory of flotation are reviewed and its adaptation to various types of ores explained. Total flotation was followed by selective flotation. At first only sulphides were treated; recently, oxides also. Various inorganic and organic chemicals and oils are used to produce the foam. The best chemical must be selected separately for each ore. The flotation processes in use at the following locations are described: For the separation of gold in the Belgian Congo, for platinum in the Transvaal, for copper and nickel at Copper Cliff, for mercury in Nevada and California, and a new process for copper developed by the Union Minière. A mineralogical examination of the ore is necessary to select the correct process. The water used must be analyzed and the acidity must be controlled during the process. CEM(31)

Trends in Blast-Furnace Development. T. L. JOSEPH. *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 11–14.

Although the pig-iron industry exhibited no new major developments in 1930, there were diversified activity and progress. Concentration of low grade ores undertaken more energetically. Larger blast-furnaces built and greater tonnage achieved by enlarging hearth diameter of furnace without increasing stock-line diameter. This resulted in twofold increase in rate of blowing. Progress shown in use of larger bell clearances, construction of hot-blast stoves, design of smaller stove checkers, and installation in a few cases of cooling plates above the mantle. Greater impetus given to use of blast-furnace gas in steel plants for underfiring coke ovens, heating open hearth furnaces, firing heating furnaces, and operating gas engines. Greater attention paid to preparation of raw materials. Sizing and sintering practiced to greater extent to improve physical properties of finer ore sizes and to obtain better furnace operation with high-moisture ores. Sintering most effective when pieces smaller than 3-mesh are eliminated. Pieces between 1/2 and 1 in. in diameter offer comparatively little resistance to gas flow. JN(31)

Flotation of Native Copper at Freda, Mich. EDWARD KOEPEL. *Engineering & Mining Journal*, Vol. 131, June 8, 1931, pages 509–512.

Valuable fines from the overflow are all minus-200 mesh. Flotation for their recovery is accomplished by effecting the sand-slime separation mechanically with a Dorr classifier, rather than hydraulically. About half of the primary slime, separated out by the Dorr classifier was cut out and pumped back to the stamp mortar to furnish the necessary volume for splash purposes. The fresh water still added at the stamp-shaft urn was introduced in such a way as to wash the slime down the stamp-shaft and prevent it from creeping up, and scoring the brasses. With these changes, the amount of fresh water used in the stamp and primary classifier became 300,000 gallons per day instead of 950,000 gallons. A flowsheet of the remodeled mill at Freda, embodying flotation, is shown. WHB(31)

On the Causes of the "Iron Disintegration" of Blast Furnace Slag. (Ueber die Ursache des "Eisenzerfalls" der Hochofenschlacke.) A. GUTTMANN & E. GILLE. *Archiv für Eisenhüttenwesen*, Vol. 4, Mar. 1931, pages 401–410; *Stahl und Eisen*, Vol. 51, Apr. 2, 1931, pages 432–433.

Report No. 19 of the Committee on Slag of the Verein deutscher Eisenhüttenleute. The so-called "iron disintegration" of blast furnace slag is due to the fact that the sulphide sulphur of the slag which is combined with calcium and manganese under normal conditions combines with iron and manganese under certain conditions of the blast furnace operation. If such slags are stored in water or humid air, they disintegrate. This phenomenon is used to recognize a suspected "iron disintegration" of a slag. This disintegration can be eliminated by a certain heat treatment above 1000° C. Slags tending to disintegration can also be stabilized by a rapid cooling of the molten slag. The chemical and X-ray investigations to elucidate the above problem are described; the results are discussed; the cause of the phenomenon are outlined. GN(31)

The Normanda Smelter. W. B. BOGGS & J. N. ANDERSON. *Transactions Canadian Institute of Mining & Metallurgy*, Vol. 33, 1930, pages 351–394; Discussion, pages 395 to 397.

See *Metals & Alloys*, Vol. 1, Oct. 1930, page 790. AHE(31)

Flotation Reagents. A. M. GAUDIN. *Engineering & Mining Journal*, July 27, 1931, pages 70–71.

Reagents that promote or increase the floatability of minerals are divided into three classes: (1) collecting oils; (2) chemical collectors; and (3) activators. Examples of each are mentioned. Complete control of the reagent feeding is essential for satisfactory results. In common practice reagents are added as follows: (1) frothers, in the liquid state; (2) collecting oils in the same manner; (3) xanthates in aqueous solution, thiocarbanilide in solid form or in a frothing oil, dithiophosphates in aqueous solution or dissolved in cresylic acid, soaps in aqueous solution, fatty acids in solid or liquid state; (4) copper sulphate in solution or solid; (5) lime in olid state or in a slurry and (6) inorganic salts in either form. WHB(31)

Magnetic Concentration. A. C. ROACH. *Canadian Mining Journal*, Vol. 52, May 29, 1931, pages 551–553.

Some experiments on Sudbury copper-nickel ores are described. Screen analyses of fine ores, assay of sizes, etc; magnetic concentration of fines as a whole, and as a whole using a screen splitter are shown, and the following conclusions drawn regarding the results of the experiments: (1) while a partial separation in treating such ores is possible, its practicability is doubtful; (2) this impracticability results from the inability of the magnet to recover chalcopyrite and some gersdorffite and finer feed materials from the range of sizes to be treated; (3) magnetic concentration would be applicable when used as a scalping process preceding some form of further concentration as tabling (and) or flotation. WHB(31)

Ball Mill Studies. A. W. FAHRENWALD & HAROLD EUGENE LEE. *Technical Publication* No. 375, *American Institute of Mining & Metallurgical Engineers*, 1931, 53 pages; **II. Thermal Determinations of Ball Mill Efficiency.** A. W. FAHRENWALD, G. W. HAMMAR, HAROLD E. LEE & W. W. STALEY. *Technical Publication* No. 416, *American Institute of Mining & Metallurgical Engineers*, 1931, 13 pages.

The behavior of balls in a mill as a function of the diameter of the mill, diameter of the balls and speed of rotation is analyzed. Experimental studies were made to determine the power required for various conditions of operation. The power required was found to depend on the speed of rotation, the ball load and the diameter of the mill. Wet grinding was found to be more efficient than dry grinding. The critical speed is defined as that speed of rotation at which the balls will remain at the periphery provided no slip occurs. The most efficient grinding results from speeds above the critical. Inasmuch as most mills are run below the critical speed, more efficient grinding would result from greatly increased speeds. The average ball diameter should be such as to give an angle of nip of 17°. Contains 9 references. Part 2. The efficiency of ball mill grinding was determined from measurements of the temperature rise of the mill and charge. Efficiency determinations by this method were much higher than those based on surface areas and surface energy values. The efficiencies determined varied from 5.9 to 24.9%. The method was considered to give accurate relative values of mill efficiency. Contains 7 references. JLG(31)

Hydrometallurgical Methods of Treatment for Zinc Concentrates from Various Canadian Ores. R. J. TRAILL, W. R. MCCLELLAND & J. D. JOHNSTON. *Canadian Department of Mines, Mines Branch Report* No. 720, 1931, pages 187–191.

Roasting tests using a zinc concentrate containing Zn 37.95% and Fe 18.06% showed that the enrichment of air with O reduces the time of roasting. With increasing Fe the insoluble Zn in the calcine increases. AHE(31)

Flotation of Hematite a Laboratory Success. A. S. ADAMS, S. M. KOBEY & M. J. SAYERS. *Engineering & Mining Journal*, Vol. 132, July 27, 1931, pages 54–55.

Experimental results show that hematite ore from the Mesabi range, as found in washing-plant tailings, can be effectively concentrated by flotation in the laboratory. Optimum conditions are determined for the consistent production of a hematite concentrate analyzing 59% Fe with 74% recovery of the Fe in the feed. WHB(31)

Effects of Grain Size, Temperature and Composition of Gas upon the Rate of Reduction of Titaniferous Magnetic Sands by Mixtures of CO and CO_2. K. IWASE & Y. SAITO. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 391–395. In English.

The results of a few experiments are expressed in curves. HWG(31)

NEW PRODUCTS

New Potentiometer Pyrometer

The Improved L & N Potentiometer Pyrometer, Micromax, which was announced in September by the Leeds & Northrup Company of Philadelphia, requires no manual adjustments. It needs no daily attention. It eliminates the "human element" in potentiometer pyrometer operation. The instrument circuit is standardized automatically, every 45 minutes or less, giving a closer adjustment than is obtained manually. Manual adjustment of the stepping action is no longer necessary, the instrument is, in every detail, a fully automatic potentiometer pyrometer.

By virtue of its microscopically sensitive balancing device, Micromax can detect and record deflections of the galvanometer pointer amounting to 1–1000th of an inch. Micrometer sensitivity makes the recorder action responsive and speedy, sending the pen, or print wheel, across the chart paper in steps that are much more accurately proportionate to the temperature change. If necessary, the recording pen, or print wheel, can step across the entire chart in less than 22 seconds, the size of each step being closely related to the extent of galvanometer pointer deflection. It is evident, especially in automatic control and where more than one temperature is being measured, that the rapid recording feature of the Micromax pyrometer is a long-desired and looked-for advance in industrial temperature control.

New All-Welded Rolled Steel Gear Blank

Lukenweld, Inc., of Coatesville, Pa., has developed and is now manufacturing all-welded rolled steel gear blanks for use in the manufacture of cut gears. This gear blank is the culmination of a considerable period of research and experimental work, and patents on the blank have been applied for by Lukenweld, Inc.

The welded steel blank, which can be employed in the manufacture of spur, herringbone and helical gears, can be made any size from 24-inches outside diameter up. The largest all-welded gear blank made up to the present time is one with a shipping weight of 4350 lbs. It is of 66 $^3/_4$″ outside diameter, 11$^3/_4$″ width of face, 4$^1/_8$″ thickness of rim and 22$^1/_2$″ diameter hub.

While the all-welded gear blanks are ordinarily made entirely from S. A. E. 1020 carbon steel, the rims can be furnished in steels of special analyses if desired.

The hubs of the all-welded gear blanks are first gas-cut from solid rolled steel of the thickness to give the desired hub diameters. The webs are gas-cut from rolled steel plate, as are the ribs, the latter being formed into channels of the required section. The webs are arc welded to the hubs, and the reinforcing channels are welded to the web structures. The final operation consists of the circular bending of the gear ring, and arc-welding in position to form the finished gear blank. Before shipment, all of the welded gear blanks are carefully and thoroughly annealed, under pyrometric furnace control. Welding operations are under rigid procedure control and in accordance with insurance welding practice.

In the manufacture of all-welded gear blanks, no patterns are required, as the gas-cutting and arc-welding are done with blueprints of the gear design as the guide. This feature, in addition to elimination of the pattern cost, permits prompt manufacture and shipment, since no time is required for pattern-making. This time-saving is an important advantage in filling requirements occasioned by gear breakdowns.

The major advantages of the all-welded gear blank, however, from the standpoint of both the gear manufacture and the gear user, are the purity and homogeneity of the thoroughly-annealed rolled steel from which the gear blanks are made. Rolled steel, as is well known, is characterized by marked freedom from blowholes, gas pockets, hard or spongy spots and other defects. The gear rings, therefore, can be uniformly cut, and the cut teeth are sound in structure. These features minimize the losses of machining time, labor and gear material which might otherwise be caused by defects in rings discovered only after considerable cutting work had been done, frequently causing the scrapping of partially-cut gears. Moreover, the life of hobs and other gear-cutting tools is said to be increased because of the tendency toward less wear in cutting on sound and homogeneous rolled steel.

New Testing Machines

The Tinius Olsen Testing Machine Company of Philadelphia, Pa., has made several new developments in their new testing machines.

Fig. 1 illustrates a new model motor driven ductility testing machine. The motor drive is unusually smooth in operation so that the load is applied evenly and the machine is practically noiseless. The power is applied and load weighed hydraulically. The cupping tool operating mechanism is similar in general construction to the mechanism drive used on other Olsen ductility testing machines. At all times during the test, the depth of cup and amount of load applied are indicated. As the material is inserted and clamped in place, the thickness of specimen is also shown by the graduated scale under the hand wheel. A stop is provided so that the increase in load is automatically stopped for any desired depth of cup. Then the load can be instantly released so that it gradually and smoothly increases up to the specimen fracture at which time both the depth of cup and amount of load are shown. The depth of cup for initial load may be adjusted to any amount desired. The dial at top of the machine indicates the depth of cup under all loads and after fracture remains in this maximum position until the specimen is removed. The motor and pump are stopped and started by the lever on top of the pump casing. Pressure is applied, released, or otherwise controlled by lever at the front of the pump housing.

Fig. 1.

Fig. 2 shows a motor driven production type Brinell testing machine. The present model is claimed to be unusually silent and fast in operation and very smooth application of load. Provision is made by the lever device on the side of the machine for operating by foot treadle if desired. Foot operation is effected by adjusting a rod running downward from front of segment on lever at the right side of the machine. All rotating parts are completely enclosed, and run in a bath of oil, thus assuring ample lubrication at all times, keeping the moving parts clean and reducing attention to a minimum.

Berzelius Zinc Smelters. R. SEIFFERT, ERICH KOCH & HERMANN MATTHIES. *Engineering & Mining Review*, Vol. 132, Aug. 24, 1931, pages 165–169.
The Duisburg and Bensberg plants of Berzelius Metallhütten have a combined annual capacity of over 40,000 metric tons of Zn and are typical of European retort practice. By-product plants produce about 75,000 tons of sulphuric acid. The smelter, the gas producers and muffle manufacture are reviewed. The muffles are made at the plant from a German clay containing: silica 50–55%, alumina 30–34%, Fe_2O_3 2%, lime 0.4%, and alkalies 0.4%, ignition loss being 9% and Seger cone 33. High-silica grog is used as an admixture with coke dust to increase the refractory qualities and to counteract the corrosive effect of the slag. The Bensberg smelter is described separately and briefly. WHB(31)

The Progress and Present State of Pig Iron Manufacture in Japan. S. UNOTORO. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 255–282.
In English. Includes statistics, analysis of ores, cinders and slags and cokes, discussion of unsuccessful attempts to utilize titaniferous iron sands, data on blast furnace practice in Japan for pig iron and ferro-alloys. HWG(31)

Reduction of Silicon Out of Silica in Iron Ores. S. TANAKA. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 283–284.
In English. In a couple of experiments greater reduction of Si was obtained in a current of 38% CO, 62% N_2, than in pure CO. HWG(31)

Smelting in the Lead Blast Furnace. Handling Rich Charges. VI. Conditions and Problems Introduced by Increasing the Ratio of Concentration. G. L. OLDRIGHT & VIRGIL MILLER. *Report of Investigations* 3088, *United States Bureau of Mines*, Apr. 1931, 7 pages; *Metal Industry*, London, Vol. 38, May 22, 1931, pages 523–524.
The Bunker Hill smelter, with 50% Pb in its charge, was examined for an insight into what may be expected in the future in the way of materials to be received and conditions of operation to be faced. AHE+PRK(31)

Modern Blast Furnace Theory and Practice. R. H. SWEETSER & S. P. KENNEY. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 429–448.
Discussion of trend of American practice and résumé of U. S. Bureau of Mines' blast furnace studies. HWG(31)

Physical Chemistry in Reduction of Iron Ore. S. SUGIMOTO. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 365–387.
In English. Mathematical discussion. HWG(31)

On the Reduction of Iron Oxides. S. SUGIMOTO. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 325–363.
In English. Discussion of laboratory experiments on reduction of various iron oxides under various conditions. HWG(31)

The Metallurgy of Gold. C. S. PARSONS. *Canadian Mining Journal*, Vol. 52, July 1931, pages 621–624.
A brief résumé of recent progress in Au metallurgy including improved processes, equipment and some of the problems involved. The operation of low-grade Au deposits is more likely to come through improvements in design and construction of existing equipment than through the invention of new process or treatment. WHB(31)

Flotation. (Die Flotation.) W. LUYKEN & E. BIERBRAUER. Verlag Julius Springer, Berlin, 1931. Cloth, 6½ × 9½ inches. Price 29 RM.
Two well-known German ore dressing authorities have produced an excellent, thoroughly scientific book on flotation. About forty pages devoted to the physical and chemical nature of flotation show the progress being made in clearing up complexities of the subject. The section on laboratory technique includes good discussions of the determination of surface tension and hydrogen-ion concentration. The chapters on flotation in the plant describe not only the cells but all auxiliary apparatus. Commercial developments, including costs, price changes and production figures, are next taken up for various minerals: copper, lead, zinc, gold, silver, mercury, tin, molybdenum, tungsten, iron, manganese, aluminum, sulphur, alkaline earth minerals, graphite and coal. The last section provides flow sheets, reagent consumption and cost for six flotation plants in different parts of the world. In the appendix are about four hundred references to English, French, German and Spanish articles and a very valuable and helpful English-German and German-English vocabulary. No attempt is made to survey the patent literature.
Throughout the book great emphasis is laid on oxide flotation; and in their introduction the authors make a statement which a few years ago would have been ridiculed: "*All minerals can be floated.*"—
J. G. Attwood (31)-B-

The Reactions in the Shaft of the Cold-Blast Furnace. COLIN D. ABELL. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, page 245.
A brief note dealing with the physical chemistry of the coldblast process. OWE(31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Some Notes on Enameling Castings. A. M. CLEVERLEY. *Foundry Trade Journal*, Vol. 44, Apr. 2, 1931, page 246.
An abstract of a paper read before the Falkirk meeting of the Institute of British Foundrymen. Deals with the design of castings suitable for enameling, the treatment of articles after enameling, the fitting of enameled castings, and the warping of castings. OWE(32)

Methods of Applying Urushi Lacquer on Metal. F. S. ARAKI. *Metal Cleaning & Finishing*, Vol 2, July 1930, pages 619–620.
Urushi or genuine oriental lacquer is a sap taken from the tree known as Urushi-no-ki (Rhus Verniciferous), which is closely allied to poison sumac. The lacquer is both beautiful and durable. It is alkali and acid proof and highly resistant to heat. Two methods of application are commonly used—the quick or ordinary and the fancy or artistic. In the former, 2 or 3 coats are customary, and sometimes only 1 is used. In the latter as many as 6 coats are applied and polishing and buffing are done with great care. MS(32)

The Effect of Smelter Atmospheres on the Quality of Enamels for Sheet Steel. A. I. ANDREWS & E. A. HERTZELL. *University of Illinois Bulletin*, No. 224, Apr. 7, 1931, 15 pages.
The purpose of this investigation was to determine the effect of various gases present in the furnace during burning operation on enamels and the relation between the smelter atmosphere and the quality of the finished enamel. The methods of investigating these influences, the analyses of the enamels used in the tests, and the analyses of the atmospheres are described in detail and the following conclusions reached: In the enamels examined, all the sodium carbonate and sodium nitrate were decomposed during the first forty minutes of smelting. When the enamel batch contained sodium nitrate, the smelter atmosphere showed a higher percentage of oxygen during the first forty minutes than without this constituent. Atmospheres of 96 to 100% N and 93 to 100% CO_2 were not deleterious to the enamels. Reducing atmospheres in the smelter were not deleterious. It can be stated, in general, that N_2CO_2 and reducing atmospheres do not destroy enamels for sheet steel as used in the tests and that sulphur dioxide is very deleterious. Ha(32)

The Warner reverse bend testing machine is shown in Fig. 3. This machine can be supplied in various sizes and types and either hand operated or motor driven. Operation of the machine consists in bending a specimen back and forth over definitely shaped jaws so that smooth bending in opposite direction is alternately effected. The jaws in the machine illustrated have a relatively small radius close to where the specimen is gripped. The two large rollers at the top of the machine are caused to oscillate back and forth and travel in a path parallel to the tops of the grip blocks in which the specimen is held. Fast speed is effected in the hand operated machine shown either by operating with the bar at the top of the machine or with the hand wheel on the large gear at the right side for slower speed and to provide more power for larger specimens the hand crank is placed on the pinion spindle as shown in the illustration. A counter just over the driving gear is provided to show the number of strokes required to break the specimen.

Fig. 2.

Fig. 3.

The Olsen Lundgren static dynamic balancing machine, as illustrated in Fig. 4, is capable of handling rotors weighing from 125 to 1000 lbs. It is suitable for dynamically balancing Diesel engine crankshafts, electrical armatures, fans, turbine rotors, rolls, etc. Other standard sizes of this Style "S" machine will balance rotors weighing from 4 to 15,000 lbs. Balancing is done with unusual rapidity and extreme accuracy. The operator can see clearly the progress of balancing operation while the machine is in motion which is a characteristic unusual in balancing machines and aids materially in fast production with accuracy.

Fig. 4.

The amount of unbalance in a rotor is determined by adjusting, while the machine is in motion, an artificial unbalance weight until it is exactly equal and opposite to the unbalance in rotor. Reading of the amount and angular position of this artificial unbalance weight then determined the amount and position of weight to be removed or added to the rotor to properly balance it. Two readings are taken, one at either end so that a corrective dynamic couple can be applied to the part being balanced. The part being balanced in the illustration is an electric motor armature. It is supported on rollers attached to a light but stiff vibrating frame constructed of high test aluminum alloy cross members and tubular steel side rails.

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy.

Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given.

Information about this service may be secured by writing to the Patent Department, METALS & ALLOYS, 810 Eighteenth Street, Washington, D. C.

United States Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Metallic refractory material. (*W-Si-Ni*). J. G. Donaldson, *et al.*, 1,820,966, 12/21/26.

Smelting of ores. F. M. Becket, 1,820,998, 4/13/28.

Method of cleaning galvanizing pots. F. L. McMeans, 1,821,105, 8/9/29.

Tuyère block for metallurgical furnaces. D. Cushing, 1,821,175, 11/11/29.

Method of preparing rare refractory metals. F. H. Driggs, *et al.*, 1,821,176, 10/1/28.

Apparatus for molding in sand. W. A. Miles, 1,821,270, 4/25/29.

Process of rolling alloy steel. H. M. Givens, 1,821,382, 11/20/29.

Process of decarburizing iron or steel or their alloys. W. Schottky, 1,821,407, 6/25/29; Germany 6/27/28.

Rolling mill. B. R. Shover, *et al.*, 1,821,483, 11/25/29.

Annealing. V. B. Browne, 1,821,493, Original filed 5/28/27, 9/26/29.

Method of decorating watch dials, etc. J. C. McFarland, 1,821,561, 6/22/28.

Separation of metals. G. U. Greene, 1,821,634, 8/8/29.

Removal of tin from antimonial lead and alloy. T. D. Jones, 1,821,643, 8/31/29.

Furnace hearth. G. C. McCormick, 1,821,658, 4/30/30.

Method of rolling sheet metal. J. M. Felton, *et al.*, 1,821,751, 7/12/28.

Process of making synthetic pig iron. T. F. Baily, *et al.*, 1,821,783, 1/28/28.

Hardening furnace with continuously operating charging device. E. Goerig, *et al.*, 1,821,832, 3/28/29; Germany 12/18/28.

Wire drawing machine and process of threading the same. E. J. McIlvried, 1,821,845, 7/8/29.

Electrodeposition of metal. (*Zinc.*) W. H. Hannay, *et al.*, 1,821,970, 2/-21/29.

Method for treating arsenious ore. A. R. Lindblad, 1,822,103, 4/22/30; Sweden 4/24/29.

Welding. C. A. Bowlus, 1,822,197, 12/6/29.

Core baking apparatus. H. L. Demmler, 1,822,205, 2/21/27.

Means for igniting gas expelled from foundry molds. F. E. McCabe, 1,822,229, Original filed 9/19/25; 3/25/27.

Process and apparatus for molding tubes. W. H. Watt, 1,822,256, 5/4/29.

Purification of ores. F. M. Becket, 1,822,266, 11/17/28.

Welding machine. W. F. Pioch, *et al.*, 1,822,371, 6/20/29.

Method of dezincing mattes and slags. M. G. Fowler, *et al.*, 1,822,396, 1/-14/29.

Core oils and process for producing same. E. H. McArdle, 1,822,411, 3/14/30.

Composition of matter and method of making the same. (*Hard metal alloy.*) E. B. Welch, 1,822,426, 9/27/29.

Method of accelerating the reaction in aluminothermic processes especially in their application to welding. W. Sander, 1,822,506, 12/23/30; Germany 11/16/29.

Induction electric furnace. E. F. Northrup, 1,822,539, 3/9/29; 1,824,618, 7/9/29.

Recovering copper from slags. M. G. Fowler, *et al.*, 1,822,588, 1/14/29.

Art of coiling hot metal stock. J. R. George, *et al.*, 1,822,589, 2/23/29.

Metallic composition and process of preparing the same. (*Hard metal.*) L. L. Wyman, 1,822,720, 7/15/29.

Steel alloy. D. F. Youngblood, 1,822,792, 5/10/29.

Method of treating aluminum base alloys which are subject to growth. R. S. Archer, *et al.*, 1,822,877, 12/22/28.

Presses for drawing sheet metal. C. J. Rhodes, 1,822,906, 10/29/29; Great Britain 12/17/28.

Method of and apparatus for handling ingots. A. R. Keller, 1,822,930, 2/-25/28.

Disappearing feeder for metallurgical furnaces. R. A. Wagstaff, 1,822,944, 10/11/27.

Process for treating metals. H. H. Stout, 1,822,939, 8/15/28.

Metallurgical process. R. F. Meyer, 1,822,995, 10/8/30.

Reverberatory furnace. W. F. Sklenar, 1,823,005, 8/15/29; Great Britain 10/22/28.

Process and apparatus for casting metals and ceramic masses according to the centrifuging method. C. Fritzsche, 1,823,037, 3/15/29; Germany 3/-21/28.

Manufacture of seamless tubes. O. Bamberger, 1,823,080, 3/25/26; Germany 2/20/26.

Method of and apparatus for producing profile strips from sheet magnesium alloys. E. de Ridder, 1,823,489, 1/28/28; Germany 1/28/27.

Apparatus for the manufacture of welded structures. T. A. Lucy, 1,823,551, 9/21/27.

Method and means for preparing metal for pouring. A. A. Holbeck, 1,823,604, 2/15/29.

Method of and apparatus for casting. W. N. Thode, 1,823,671, 1/2/29.

Coating and heat treating apparatus. A. O. Austin, 1,823,675, 2/12/25.

High temperature thermocouple. H. C. Staehle, 1,823,706, 11/12/29.

Method of producing openings through hard metal compositions. G. F. Taylor, 1,823,709, 1/22/31.

Drying and roasting furnace. G. E. Connolly, 1,823,787, 5/1/30.

Electromagnetic testing of steel wire ropes and other articles of magnetizable material. T. F. Wall, 1,823,810, 12/20/28; Great Britain 12/20/27.

Process of obtaining beryllium and aluminum compounds. C. B. Sawyer, *et al.*, 1,823,864, 10/14/30; Canada 1/6/27.

Sheet-metal working machine. P. R. Hahnemann, 1,822,697, 10/4/29.

Casting machine. J. Polák, Re 18,202 (Original 1,717,254, 6/11/29), 6/8/31; Czechoslovakia 9/1/27.

Induction furnace. P. H. Brace, 1,823,873 & 1,823,874, 1/23/30 & 4/23/30.

Pyrites roasting. J. E. Little, 1,823,907, 5/4/28.

Induction furnace. T. H. Long, 1,823,908, 9/20/30.

Process for the production of silver plated metal articles such as table requisites. G. Henke, 1,823,938, 1/27/30; Germany 12/11/28.

Induction furnace. N. R. Davis, 1,823,970, 9/26/29; Great Britain 10/9/28.

Apparatus for shearing flanges from ingots. W. J. Schultz, *et al.*, 1,823,991, 8/20/29.

Method and apparatus for rolling sheets. R. J. Wean, 1,824,001, 10/31/29.

Foundry molding machine. T. W. Bullock, 1,824,009, 9/14/29; Great Britain 10/1/28.

Ladle stopper construction. A. J. Jackson, 1,824,019, 10/2/29.

Recovery of precious metals from refractory ores. R. F. Meyer, 1,824,093, 12/13/28.

Process for electrolytic deposit of heavy metals. M. Schlötter, 1,824,100, 1/16/29; Germany 11/9/28.

Welding method. (*Facing with hard metal.*) H. J. Morgan, 1,824,166, 1/-16/29.

Rolling mill. A. F. Jobke, 1,824,211, 5/2/28.

Underwater torch and method therefor. E. Ellsberg, 1,824,397, 12/20/27.

Apparatus for demagnetizing magnetically conveyed material. W. McKee, 1,824,403, 6/11/30.

Heat treating razor blade strips. T. C. Sheehan, 1,824,410, 7/12/29.

Hotbed. W. McKee, 1,824,439, 8/28/29.

Pattern lifting device. D. B. Dimich, 1,824,468, Original 10/23/29; 12/-26/30.

Intersupported disk for furnace conveyors. F. A. Fahrenwald, 1,824,470, 12/10/30.

Process for smelting material containing tin oxide. M. G. Freise, *et al.*, 1,824,-475, 2/19/30; Germany 3/4/29.

Apparatus for operating shaft furnaces in the thermal treatment of granular material. O. Hubmann, *et al.*, 1,824,483, 3/26/30; Germany 2/3/27.

Rolling sheets. J. Kennedy, 1,824,496, 1/19/29.

Method of treating wire. R. C. Pierce, 1,824,568, 10/25/29.

Method of making polished annealed stainless steels. F. Locke, 1,824,608, 6/18/29.

Means for feeding sheet bars to furnace conveyers. A. L. Larsen, 1,824,742, 7/31/30.

Furnace. E. G. de Coriolis, 1,824,747, 9/8/30.

Process of heat treating metal. J. J. Bowden, 1,824,865, 12/29/30.

Recuperative soaking pit. A. L. Culbertson, 1,824,876, 9/9/27.

Tuyère. L. M. Nesselbush, 1,824,919, 7/17/29.

Pickling of stainless steel. N. H. Schermer, 1,824,932, 8/21/30.

Metallurgical process and apparatus. F. Lawaczech, 1,824,960, 12/22/27. (Original 3/16/27); Germany 12/17/25.

Alloys and process for improving workability of same. N. B. Pilling, 1,824,966, 9/30/27.

Metallurgical furnace. H. Navratiel, 1,825,011, 12/27/28; Germany 1/2/28.

Extrusion press. F. Singer, 1,825,017, 8/25/30; Germany 4/2/28.

Furnace. W. Grothe, 1,825,059, 7/9/28.

Electric welder. E. A. Hobart, 1,825,064, 7/19/29.

Adjustable die (*for sheet metal working*). W. C. Johnson, 1,825,067, 10/24/29.

Furnace conveyor. R. J. Wean, 1,825,107, 10/6/30.

Metallic lining for high temperature vessels. S. T. McDermott, 1,825,154, 7/23/30.

Electrodeposited pattern. (*For a casting.*) A. K. Laukel, 1,825,189, 12/3/28.

Recovery of metals and metal compounds soluble in ammoniacal liquors. L. Schlecht, *et al.*, 1,825,211, 3/29/28; Germany 4/27/27.

Optical pyrometer. R. Hase, 1,825,229, 12/9/26; Germany 2/26/26.

Production of metals from their carbonyls. A. Mittasch, *et al.*, 1,825,241, 3/18/29; Germany 3/26/28.

Process of producing castings of magnesium and high grade magnesium alloys, A. L. Mond, 1,825,242, 12/14/29; Great Britain 12/19/28.

Centrifugal molding apparatus. W. H. Beatty, 1,825,302, 6/17/29.

Electrode holder (*for welding electrodes*). H. H. Heckmann, 1,825,314, 1/-30/28.

Method of extrusion and apparatus therefor. C. O. Evans, 1,825,343, 3/5/30.

Regenerative-furnace-controlling apparatus. W. Sykes, 1,825,372, 1/22/30.

Annealing furnace. H. Alinder, *et al.*, 1,825,380, 7/23/28; Great Britain 6/29/28.

Combined goggles for grinding and welding. A. R. Dobbs, 1,825,386, 5/20/31.

Apparatus for testing physical properties of materials. R. Esnault-Pelterie, 1,825,387, 12/14/26; Great Britain 6/30/26.

Hot top for ingot molds. M. G. Dumas, 1,825,445 & 1,825,446, 12/5/29 & 8/23/30.

Method of reclaiming stainless steel scrap. L. B. Lindemuth, 1,825,463, 7/30/30.

Process of reducing the quantity of sulphurous acid gas set free from copper glance on its roasting. M. Miyake, 1,825,536, 10/18/29, renewed 8/-24/31.

Corrugated pot. C. H. Stevenson, 1,825,556, 7/12/28.

Method of treating metals and treating agent therefor. F. J. Wilson, *et al.*, 1,825,565, 12/17/28.

Cutting and welding machine. A. Schmidt, 1,825,606, 5/17/29; Austria 5/19/28.

Austrian Patents

Subject of Invention, Patentee, Patent No. and Date of Beginning of Term of Patent.

Electric bright-annealing furnace. Siemens-Schuckertwerke Akt.-Ges., 124,-245, 4/15/31.

Method of preventing surface decarburization and carburization in the annealing of steels containing carbon. Vereinigte Stahlwerke Akt.-Ges., 124,246, 4/15/31.

Process for locally hardening objects by nitriding. Aubert & Duval Frères, 124,247, 4/15/31.

Ironless induction furnace for making alloys, particularly iron-silicon alloys. Siemens-Schuckertwerke Akt.-Ges., 124,250, 4/15/31.

Steel and cast iron alloys which can be hardened by nitriding. Aubert & Duval Frères, 124,268, 4/15/31.

Process for preparing ore slimes for blast roasting, on a Dwight-Lloyd machine for example. Metallges. Akt.-Ges., 124,264, 4/15/31.

Means for regulating electric arc furnaces. A. E. G. Union Elektricitäts Ges., 124,251, 4/15/31.

Process and anode for increasing the thickness of the electrolytic deposit at the points of forks and the edges of spoons. Berndorfer Metallwarenfabrik A. Krupp Akt.-Ges., 124,266, 4/15/31.

Process for coating metallic objects with one or more metals or alloys. Research Corp., 124,253, 4/15/31.

Process for increasing the radiation constant or the heat absorptivity and emissivity of metallic surfaces, objects, etc. Vereinigte Aluminium-Werke Akt.-Ges., 124,257, 4/15/31.

Electric soldering device. Elektrische Löt-u. Schweiss G. m. b. H., 124,216, 4/15/31.

Device for electric spot welding of seams. A. E. G. Union Elektricitäts Ges., 124,218, 4/15/31.

Process for coating objects which are to withstand a high temperature, such as metals, graphite, electrodes, etc., with a hard, glossy, metallic coating of graphite. Presslicht-Patentverwertungsges. m. b. H., 124,214, 4/15/31.

Process for protecting sheet iron vessels against chemical corrosion by coating them with steel. R. Novelly, 124,534, 4/15/31.

Steel die and process for making the same. Aubert & Duval Frères, 124,553, 7/15/30.

British Patents

Note: When the date applied for differs from the date on which the application was lodged at the British Patent Office, the former date is given, followed by *.

Subject of Invention, Patentee, Patent No. and Filing Date.

Process and apparatus for plating metal articles. Major Engineering Corp., 354,706, 2/7/30.

Manufacture of strip-like material. Cold Metal Process Co., 354,707, 12/-19/29*.

Production of magnesium alloys. Dow Chemical Co., 354,744, 3/11/30.

Manufacture of refractory metals such as tungsten. General Electric Co., Ltd., *et al.*, 354,785, 5/10/30.

Nickel-chromium alloys. General Electric Co., Ltd., *et al.*, 354,765, 5/12/30; 355,083, 9/29/30.

Process for treating vanadium ores, and particularly vanadates of lead and of other metals. A. Gildemeister, *et al.*, 354,816, 6/24/29*.

Processes of coating metals. British Thomson-Houston Co., Ltd., 354,887, 5/28/29*.

Methods of and machines for making welded tubing. Jackson Tube Co., Inc., 354,913, 6/11/30.

Mounting means for the heating-elements of electric resistance furnaces. Hevi Duty Electric Co., 354,928, 6/22/29*.

Anodes for electroplating. Udylite Process Co., 354,939, 11/13/29*.

Machines for welding. E. G. Budd Mfg. Co., 354,947, 8/1/29*.

Tubes for use in highly heating molten metals, liquids, vapors and gases. F. Krupp Akt.-Ges., 354,965, 7/20/29*.

Mounting rolls for cold-rolling mills. Maschinenbau-Akt.-Ges. Vorm. Ehrhardt & Sehmer, *et al.*, 354,969, 7/16/30.

Welding-agents. Vereingte Stahlwerke Akt.-Ges., 354,995, 8/19/29*.

Apparatus for bending tubes. British Tube Mills, Ltd., *et al.*, 355,027, 8/-16/30.

Tungsten carbide. British Thomson-Houston Co., Ltd., 355,041, 8/29/29*.

Foundry molding-machines. R. F. Ringle, 355,044, 9/2/30.

Treatment of copper matte. United Verde Copper Co., 355,078, 9/25/29*.

Rock drills, cutting-picks and other hard metal tools. F. Krupp Akt.-Ges., 355,127, 8/21/30*; 356,029, 8/22/30*.

Process for lining tube branches, consisting of welded tubes, with a protective internal coating. R. Traut, 355,148, 8/12/30*.

Method of manufacturing profiled metal pieces, such as metal plates, strips or the like. H. Seiferth, 355,152, 2/1/30*.

Electric arcs for welding and like purposes. Presslicht-Patent-Verwertungs Ges., *et al.*, 355,153, 12/2/29*.

Billet heating furnaces. Scovill Manufacturing Co., 354,717, 4/7/30*.

Processes of treating iron ores. Comstock & Wescott, Inc., 355,235, 10/-24/29*.

Process for obtaining iron from iron carbonyl. Vereinigte Stahlwerke Akt.-Ges., 355,302, 3/8/29*.

Process for producing a coating-composition for protecting surfaces against rust, decomposition, heat, fire and the like. R. T. Victoria Vegyeszeti Müvek, 355,266, 1/29/30*.

Coating metals. J. H. Gravell, 355,286, 3/4/30*.

Process for coating metal bodies with tungsten bronzes and/or molybdenum bronzes. Egyesult Izzolampa es Villa-Mossagi Reszvenytarsasag, 355,334, 12/23/29*.

Water-cooled molds for casting metals, and method of using same. Heraeus Vacuumschmelze Akt.-Ges., *et al.*, 355,395, 10/12/29*.

Zinc alloys. Illinois Zinc Co., 355,422, 10/18/29*.

Magnetic alloys. Callender's Cable & Construction Co., Ltd., *et al.*, 355,456, 7/14/30.

Method of and apparatus for coating wire. Johnson Steel & Wire Co., Inc., 355,463, 7/17/30.

Four-high mills. Maschinenbau-Akt.-Ges. Vorm. Ehrhardt & Sehmer, 355,487, 9/16/29*.

Process for patterning metallic hollow cylindrical or the like bodies. K. Takeda, 355,523, 9/3/30.

Manufacture of metal tubes and other metal tubular articles. Wellman Seaver Rolling Mill Co., Ltd., *et al.*, 355,524, 9/4/30.

Electrodes for use in electric arc-welding or the fusion-deposition of metals. Quasi-Arc Co., Ltd., *et al.*, 355,552, 9/25/30.

Device for detecting leakage in a vessel containing an electrically conductive liquid bath. Vereinigte Stahlwerke Akt.-Ges., 355,594, 12/3/29*.

Process for converting ferro-phosphorus rich in silicon into ferro-phosphorus of high phosphorus-content free from or poor in silicon. I. G. Farbenindustrie Akt.-Ges., 355,610, 12/17/29*.

Conveyer for metal sheets. Copperized Steel, Ltd., 355,628, 12/27/29*.

Hot-blast stoves. H. A. Brassert & Co., 355,674, 3/19/30.

Method of producing hard alloys. Vereinigte Stahlwerke Akt.-Ges., 355,782, 3/26/29*.

Connectors for welding cables and welding heads. E. G. Budd Mfg. Co., 355,-784, 4/29/29*.

Continuous-rolling mechanism for rolling bands and strips. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 355,698, 9/3/29*.

Method of propagating endothermic reactions in electric arc furnaces. Buffalo Electric Furnace Corp., 355,700, 6/27/29*.

Means for supporting resistor coils in electric furnaces. D. F. Campbell, *et al.*, 355,701, 5/19/30.

Roasting of ores containing iron and copper sulphides. H. K. A. Lassen, 355,664, 5/19/30.

Process for the manufacture of aluminum and its alloys. T. R. Haglund, 355,-792, 5/22/30.

Welding of metal sheets. L. W. Blanchard, 355,688, 5/26/30.

Manufacture of coated metal sheets. L. W. Blanchard, 355,796, 5/26/30.

Recuperative counter-flow furnace. Hevi Duty Electric Co., 355,839, 6/-5/29*.

Treatment of zinciferous materials for the removal of cadmium or cadmium together with lead. New Jersey Zinc Co., 355,840, 10/15/29*.

Method of metallizing articles of organic origin. K. Richter, 355,848, 6/6/30.

Machines for pushing foundry molds out of their boxes. British Insulated Cables, Ltd., *et al.*, 355,889, 7/5/30.

Mandrels of tube-forming apparatus. Demag Akt.-Ges., 355,898, 7/14/30.

Subaqueous burner for autogenous cutting and welding. H. Topper, 355,909, 9/5/29*.

Process for increasing the resistance to corrosion of objects made from alloys of magnesium with manganese. I. G. Farbenindustrie A.-G., 355,920, 8/23/29*.

Furnace for melting metals of relatively low-melting points. W. G. Armstrong, Whitworth & Co., Ltd., *et al.*, 356,037, 11/12/30.

Refining copper. J. Leemans, *et al.*, 356,077, 1/8/31.

Presses for drawing hollow bodies. F. Krupp A.-G., 356,082, 1/22/30*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Device for casting metals. E. Bornand, *et al.*, 314,096, 12/11/29.

Metal-protected mirror. S. C. Langdon, 314,148, 8/22/30.

Process of manufacturing alloys. (*Cu, Si and Co, Ni, Cr or Fe.*) The American Brass Co., 314,185, 1/15/29.

Process of treating nickel-copper solutions to remove iron. The Falconbridge Nickel Mines, Ltd., 314,218, 10/10/30.

Process of decomposing titanium ores. I. G. Farbenindustrie Akt.-Ges., 314,219, 9/28/28.

Method of treating malleable iron. Fittings, Ltd., 314,223, 4/24/31.

Metallurgical furnace. The New Jersey Zinc Co., 314,247–314,249, 11/4/30.

Tube manufacture. The Union Metal Mfg. Co., 314,275, 2/11/29.

Apparatus for making tapered tubular poles. Same patentee, 314,276, 12/-5/30.

Welding method. Same patentee, 314,277, 12/5/30.

Tubular column forming machine. Same patentee, 314,278, 12/5/30.

Electrode holder (for electric furnaces). W. H. Walter, 314,319, 5/13/31.

Heating furnace (for billets, sheet bars, etc.). A. L. Culbertson, 314,335, 12/-3/30.

Method of preparing metal for painting. J. H. Gravell, 314,344, 2/10/30.

Foundry facing composition. B. F. Wallace, 314,377, 6/23/30.

Apparatus for manufacturing castings. J. E. Wright, 314,380, 5/10/30.

Process of electrolytically refining metallic aluminum. Aluminium Industrie Akt.-Ges., 314,384, 12/2/29.

Starting cathode for the electrolytic refining of copper and other metals. The United States Metals Refining Co., 314,437, 3/14/30.

Electric furnace. H. I. Altshule, *et al.*, 314,458, 4/17/29.

Electric welding apparatus. E. Bornand, *et al.*, 314,460, 5/1/31.

Apparatus for producing rolled bodies from pulverized materials. C. A. Brackelsberg, 314,474, 12/2/29.

Apparatus for galvanizing thin chains. M. Fessler, 314,489, 7/29/30.

Device for guiding the mandrel bars of tube push benches. Demag Akt.-Ges., 314,586, 10/29/30.

Metal coating method. The Hudson Motor Car Co., 314,607, 3/15/29.

Centrifugal casting machine. The Paper & Textile Machinery Co., 314,624, 11/23/29.

Electric arc welding plant. The Quasi-Arc Co., Ltd., 314,628, 2/24/31.

Process of treating ores. (*Conversion to water-soluble sulphates.*) E. A. Ashcroft, 314,706, 7/22/30.

Press. E. Haverbeck, 314,729, 2/27/31.

Paper machine wire manufacture. C. Johnson, 314,738, 6/4/31.

Heat-absorbing method for metallic surfaces. (*Production of oxidic layer.*) E. Roth, 314,764, 11/26/29.

Process of producing metal nitrides. R. R. Walter, 314,776, 5/12/28.

Process of casting metals or alloys. British & Dominions Feralloy, Ltd. 314,797, 2/7/31.

Method of making metal dies. The Edward G. Budd Mfg. Co., 314,799, 5/8/29.

Process of preparing rare metals (U) by electrolytic decomposition. The Canadian Westinghouse Co., Ltd., 314,802, 12/31/28.

Method of preparing rare refractory metals. (*W, Mo, Cr, U.*) The Canadian Westinghouse Co., Ltd., 314,805, 9/20/29.

Alloy. (*Zn-Cu-Al-Fe-Mn.*) Same patentee, 314,810, 5/23/30.

ngot mold. The Firth Sterling Steel Co., 314,837, 5/16/30.

Process of treating ores. The Sulphide Corp., 314,884, 5/27/30.

Manufacture of axes. Vaughan & Bushnell Mfg. Co., 314,893 & 314,894, 4/26/30.

Centrifugal casting method. W. H. Millspaugh, 314,911, 6/4/29.

Apparatus for melting, casting and feeding linotype metal. E. E. Beard, 314,-921, 1/24/30.

Process for manufacturing iron having good machining properties. F. Borggrafe, 314,923, 7/16/29.

Hot top for ingot molds. W. M. Charman, 314,925, 8/8/30; 315,121, 12/-13/29.

Lining for ingot mold hot tops. W. M. Charman, 314,926, 11/19/30.

Metal plate flanging machine. V. C. Norquist, 314,969, 3/18/31.

Press for producing cable sheathings. Felten & Guilleaume Carlswerk Akt.-Ges., 315,038, 10/18/29.

Metal ribbon manufacture. The Griscom-Russell Co., 315,056, 2/13/31.

Tarnish resistant and rust proof alloy. (*Fe-Ni-Cr.*) The International Nickel Co., Inc., 315,059, 11/28/27.

Process of recovering nickel. Same patentee, 315,060, 10/11/29.

Ferrous base article. The Molybdenum Corp. of America, 315,071, 3/23/29.

Mold wiper for hot tops. W. M. Charman, *et al.*, 315,122, 8/8/30.

Galvanizing rack centrifuge. H. B. Newhall, 315,126, 9/26/30.

Ore roasting furnace. W. J. Cummings, *et al.*, 315,136, 9/2/30.

Cross rolling machine. P. B. Abramsen, 315,139, 2/4/30.

Aluminum silicon alloy. The Aluminium Limited, 315,200–315,202, 9/6/30, 9/6/30 & 9/9/30.

Method of making metal stampings. The Edward G. Budd Mfg. Co., 315,215, 5/30/30.
Method of casting metal sheets. The Cleveland Graphite Bronze Co., 315,229, 12/16/29.
Metal working machine. The Motor Products Corp., 315,279, 5/12/30.
Method of treating mattes and slags. The United Verde Copper Co., 315,321, 1/9/30.
Method of recovering copper from slags. Same patentee, 315,322, 1/9/30.
Apparatus for manufacturing metallic sheets, strips or wire. S. O. Cowper-Coles, 315,354, 1/5/31.
Apparatus for making profile metal articles. H. Seiferth, 315,409, 1/8/31.
Alloy. (*Cu-Mn-Zn.*) J. N. White, 315,419, 11/8/30.
Metallurgical furnace. The Canadian Westinghouse Co., Ltd., 315,440, 5/20/27.
Welding rod. The Steel Co. of Canada, Ltd., 315,502, 3/26/30.
Ore metallurgy. The United Verde Copper Co., 315,513, 9/24/30.
Method of treating mattes. Same patentee, 315,514, 9/24/30.

Danish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for making tools having a homogeneous structure and great hardness. F. Krupp Akt.-Ges., 44,289, 7/24/29.
Process for tinning "rustless" chromium steel or chrome-nickel steel. AB. Separator, 44,306, 11/28/30.
Process for making welding wire. Vereinigte Stahlwerke Akt.-Ges., 44,308, 7/23/30.
Process for electroplating bulk goods in drums. Soc. An. Waldberg, 44,353, 11/4/29.
Chrome-iron alloy for spraying and rustless objects produced therewith. B. Vervoort, 44,390, 8/12/29.
Means for preventing corrosion in mercury vapor rectifiers. Fusi Denki Seizo K. K., 44,393, 2/10/30.
Process for forming the blade or bowl of spatulate metallic objects, especially silverware. K. A. Marthinson, 44,428, 3/27/30.
Machine for extruding metal tubing, or similarly functioning machines. W. T. Henley's Telegraph Works Co., Ltd., 44,466, 6/21/30.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Machine for plugging tap holes. E. Schiegries, 710,335, 1/31/31.
Apparatus for treating foundry sand and similar products. E. F. Dehomme, 710,144, 1/29/31.
Process for making metal tubes covered with wood veneer. Theodor Muller & Co. G. m. b. H., 710,153, 1/29/31.
Improvements to drawing and coiling apparatus. Scovill Mfg. Co., 710,185, 9/12/29.
Improvements to electric heating elements. Geo. Bray & Co., Ltd., 710,154 & 710,155, 1/30/31.
Automatic mechanism for regulating electric arcs. R. Sarazin, Addition 39,043 (1st addition to 682,422, 9/28/29), 9/5/30.
Process for making tubes which are ready for shipment after being coated with a rust-preventive composition. Vereinigte Stahlwerke Akt.-Ges., 710,647, 2/5/31.
Drive for hot beds having oblique rollers. Demag Akt.-Ges., 710,679, 2/6/31.
Improvements to ferrous alloys. Cie. Nationale des Radiateurs, 710,400, 2/2/31.
Machine for plugging tap holes. Vereinigte Stahlwerke Akt.-Ges., 710,689, 2/6/31.
Process for the electrolytic extraction of aluminum from a double chloride. E. Daudonnet, 710,706, 4/19/30.
Rolling process. G. Muller, 710,450, 2/4/31.
Improvements in the casting of metals and alloys. British & Dominions Feralloy, Ltd., 710,463, 2/4/31.
Draw-bench with tractive-force regulator. Siegener-Maschinenbau Akt.-Ges., *et al.*, 710,545, 1/30/31.
Improvements to machines for working metal by means of electricity. J. E. J. Languepin, 710,722, 5/2/30.
High-frequency vacuum furnace. Telefunken Ges. für Drahtlose Telegraphie m. b. H., 710,618, 2/5/31.
Heating grids for electric resistance furnaces. W. S. Smith, *et al.*, 710,631, 2/5/31.
Centrifugal apparatus for the electrolytic deposition of metals. Soc. An. Waldberg, 710,753, 5/8/30.
Surface-hardened journal. Deutsche Edelstahlwerke Akt.-Ges., 710,287, 5/12/30.
Machine for casting by projection. Eckert & Ziegler G. m. b. H., 710,868, 1/20/31.
Process for making metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 710,792, 2/7/31.
New light metal alloy. The Birmingham Aluminum Casting (1903) Co., Ltd., 710,908, 2/5/31.
Improvements to processes and apparatus for treating ores containing sulphides. Nichols Copper Co. 710,988, 2/10/31.
Process for the electrolytic extraction of zinc. L. Cambi, *et al.*, 711,029, 2/11/-31.
High-speed steel. E. Becker, 711,059, 2/12/31.
Improvements to alloys of palladium and rhodium, and process for producing them electrolytically. Precious Metals Development Co., 711,081, 2/12/31.
Process for preventing surface decarburization in annealing or other heat treatment, especially of steel. Fagersta Bruks AB., Addition 39,109 (1st addition to 690,203, 2/15/30), 6/6/30.
Improvements to upsetting or forging machines. Omes Holding Co., Ltd., 710,823, 2/9/31.
Process for making seamless tubes of steel and other metals. Timken Holding & Development Co., 710,865, 1/20/30.
Process for making spiral-seam pipe and machine for working this process. T. M. A. Stewart, 711,079, 2/12/31.
Improvements in the mounting of wire-drawing dies made of special alloys. Cie. Générale des Filières en Diamant, 711,090, 2/13/31.
Machine for the impact testing of metals. A. Plana, 710,853, 2/12/31.
Anode for electrolysis. C. Conradty Fabrik Elektrischer & Galvanischer Kohlen, 711,024, 2/11/31.
Carbon electrode with graphite core. Same patentee, 711,075, 2/12/31.
Vertically displaceable furnace door. O. Poli, 710,888, 1/20/31.
Process for the production of pure metals. I. G. Farbenindustrie Akt.-Ges., 711,305, 2/14/31.
Process and machine for machining rolls, especially grooved rolls of pilger mills. Mannesmannröhren-Werke, 711,321, 2/14/31.
Process for covering iron or steel objects with aluminum or aluminum alloys. F. Nilsson, 711,364, 2/16/31.
Automatic arc welding machine. Soc. An. de Anciens Etablissements Achard et Cie., 711,149, 5/14/30.
Electrode equalizing system for automatic arc welding machines. R. Sarazin, 711,317, 2/14/31.
Thermo-electric pyrometer. La Pyrometrie Industrielle, 711,173, 5/17/30.
Improvements to electric heating apparatus, particularly to low- or medium-frequency induction furnaces. R. Dufour, 711,225, 1/24/31.
Process and automatically controlled apparatus for electrolytic deposition. A. Jacob, Addition 39,149 (1st addition to 683,888, 10/24/29), 10/6/30.
Improvements to hot tops for ingot molds. W. M. Charman, 711,509, 2/9/31.
Improvements to vertical furnaces for roasting clays or ores. A. Hirt, *et al.*, 711,631, 5/22/30.
Process for the production of zinc. Soc. L'Air Liquide, 711,652, 5/24/30.
Iron objects. I. G. Farbenindustrie Akt.-Ges., 711,392, 2/17/31.
Metal strip and process for making the same. The Cleveland Graphite Bronze Co., 711,466, 1/21/30.
Improvements to machines for making tubing. Soc. An. des Hauts Fourneaux et Fonderies de Pont-à-Mousson, 711,546, 2/18/31.
Optical pyrometer. Siemens & Halske Akt.-Ges., 711,506, 2/9/31.
Contact clamps for electric upsetting machines. S. A. Gatti & Giacchino, 711,-936, 2/24/31.
Process for nitriding metals. Electro Metallurgical Co., 711,747, 2/21/31.
Cementation process. Same patentee, 711,748, 2/21/31.
Process for cementation by nitriding. Same patentee, 711,749, 2/21/31.
Process for heat treating rails. Soc. An. d'Ougrée Marihaye, 711,815, 2/-23/31.
Process for treating ores. Sulphide Corp., 711,826, 5/31/30.
Improvements in the production of billets, sheet bars and the like. Timken Holding & Development Co., 711,850, 1/27/31.
Process for the centrifugal casting of cylindrical objects. Soc. An. des Anciens Etablissements Cochaux, 711,805, 2/23/31.
Apparatus for the surface hardening of the inner walls of hollow objects. F. Klopp, 711,824, 2/24/31.
Apparatus for making foundry molds and cores. G. Zimmermann, 711,845, 1/21/31.
Molding press for metals and non-metallic materials. E. Thieslack, 711,847, 1/22/31.
Improvements in the cleaning of metal sheets. Edward G. Budd Mfg. Co., 711,870, 2/5/31.
Pressure-casting machine. E. P. Fradin, 711,957, 5/31/30.
Machine for testing metals, particularly cast iron. Cie. Générale des Conduites d'Eau, 711,830, 8/4/30.
Process and device for mixing gas or vapor with molten materials, particularly metals or alloys. Blei & Silberhütte Braubach G. m. b. H., *et al.*, 712,354, 2/28/31.
Process for extracting iron and metals of the iron group. Vereinigte Stahlwerke Akt.-Ges., 712,363, 2/28/31.
Improvements to non-tarnishing silver and to the process for making it. Precious Metals Development Co., Inc., 712,431, 3/2/31.
Gold alloy, especially for jewelry. Soc. An. Cartier, 712,507, 6/14/30.
Aluminum alloys. Cie. de Produits Chimiques et Electrométallurgiques Alais, Froges et Camargue, 712,526, 6/17/30.
Treatment and production of lead and products made therefrom. P. Gamichon, 712,528, 712,544 & 712,554, 6/17/30, 6/18/30 & 6/19/30.
Process for working metals with the aid of electrically produced heat. W. Schabelitz, 712,370, 2/28/31.
Device for driving the pistons of die casting machines. Braunschweiger Hüttenwerk G. m. b. H., 712,421, 3/2/31.
Process for making foundry molds having an inner facing. The Metal Castings Holding Corp., 712,426, 3/2/31.
Process for making molded objects from powdered metals. I. G. Farbenindustrie Akt.-Ges., 712,462, 3/3/31.
Improvements to electric welders. L. Bourdelles, 712,552, 6/18/30.
Die. R. Charbonnier, 712,558, 6/19/30.
Draw press. L. Schuler Akt.-Ges., 712,576, 3/3/31.
Method of localizing electrolytic deposits of metal. Orfévrerie Christofle, Bouillet & Cie., 712,505, 6/14/30.
Method of mounting the housing rollers of blooming and plate mills. Schloemann Akt.-Ges., 712,672, 3/5/31.
Improvements to hard metal compositions and to processes for making the same. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, Additions 39,216 & 39,222 (8th & 9th additions to 654,210, 4/4/28), 7/31/30 & 8/29/30.
Improved aluminum alloy. Rolls-Royce Ltd., Additions 39,231, 39,234 & 39,235 (2nd, 3rd & 4th additions to 683,272, 10/14/29), 9/18/30, 9/-23/30 & 9/23/30.
Process for preparing cadmium from oxidic compounds of cadmium. Metallges. Akt.-Ges., Addition 39,269 (1st addition to 699,466, 10/24/29), 11/17/30.
Device for regulating the feed of the wire in automatic arc welding machines. Allgemeine Elektricitäts Ges., 712,631, 3/4/31.
Apparatus for hardening the outer surface of cylindrical objects. F. Klopp, 712,735, 3/6/31.
Electric welding machines. J. E. J. Languepin, Addition 39,259 (1st addition to 695,066, 8/13/29), 11/12/30.
Improvements in the nitriding of ferrous alloys. Electro Metallurgical Co., 712,749, 3/6/31.
Process and means for obtaining a uniform circulation of the bath in converters. K. Thomas, *et al.*, 712,793, 12/8/30.
Device for transferring rolled bars from runways to a cooling bed. Demag Akt.-Ges., 712,985, 3/10/31.
Device for moving several rolled bars through the runway leading to the cooling bed. Demag Akt.-Ges., 712,986, 3/10/31.
Process for obtaining gray cast iron of predetermined composition, in the cupola. Soc. Alsacienne de Constructions à Mulhouse, *et al.*, 713,023, 3/11/31.
Process for regenerating corroded metallic coatings. Durener Metallwerk Akt.-Ges., 712,753, 3/6/31.
Metal-drawing press. Scovill Mfg. Co., 712,785, 4/26/30.
Die-casting mold. Braunschweiger Hüttenwerk G. m. b. H., 712,934 & 712,935, 3/9/31.
Device for clamping molds for the die casting of bearings or the like. Same patentee, 712,936, 3/9/31.
Improvements in the drawing of metals. Electro Metallurgical Co., 712,937, 3/9/31.
Multiple purpose wrench for autogenous welding stations. H. Labbe, 712,989, 3/10/31.
Induction furnace. Siemens & Halske Akt.-Ges., 712,915, 3/9/31.
Welding blowpipe. Allgemeine Elektricitäts-Ges., 712,767, 3/7/31.
Suspension of refractory blocks. L. Tournemaine, 712,828, 3/17/31.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process for separating metals from solutions. Metallraffinerie Berlin G. m. b. H., 531,377, 3/7/30.

Process for filtering light metals such as magnesium or aluminum and their alloys. British Maxium, Ltd., 531,378, 3/11/28; France 11/7/27.

High-frequency furnace for refining metals, alloys or metallic mixtures by volatilization of metallic constituents. Hüttenwerke Trotha Akt.-Ges., 531,506, 5/1/27.

Process for smelting zinciferous material. The New Jersey Zinc Co., 531,379, 7/26/27; U. S. 1/27/27.

Process for separating zinc from iron. Soc. d'Electrochimie, d'Electrométallurgie et des Aciéres Electriques d'Ugine, 531,380, 8/6/29; France 6/22/29.

Deoxidizing metals and alloys. W. Reitmeister, 531,507, 6/17/28.

Bearing metal alloy. (Lead base.) Th. Goldschmidt Akt.-Ges., 531,631 (Addition to 408,229), 12/28/21.

Process for the electrolytic separation of copper from copper iodide solutions. Asociacion de Productores de Yodo de Chile, 531,530, 10/30/28.

Process and means for forming metallic coatings, especially on wires. Allgemeine Elektricitäts-Ges., 531,648, 5/3/30.

Device for lead-coating iron, copper or other pipes. O. Semmler, 531,649, 20/27/29.

Process for improving wooden objects by metal spraying. E. von Mallitz, 531,391, 7/18/30.

Process and device for the uniform spraying of plates, particularly for etching metal printing plates. F. A. Henrici, 531,533, 2/25/30.

Device for converting lead and lead oxides into lead dust. H. Heinicke, 531,392, 7/23/29.

Wire cooling device for slipless multiple wire-drawing machines. W. Nacken, 531,885, 9/9/30.

Mechanically driven tubing extrusion press. F. Singer, 531,962 (addition to 520,289), 12/6/27.

Process for making armored lead pipe. F. Barmé, 531,771, 8/6/30.

Device for closing the tap holes of metallurgical furnaces, particularly blast furnaces. Vereinigte Stahlwerke Akt.-Ges., 531,721, 10/29/30.

Method of heating open-hearth furnaces with coke oven gas. W. Heiligenstaedt, 532,008, 4/13/28.

Electric arc welding device. Allgemeine Elektricitäts-Ges., 531,737, 6/13/29.

Cut-off device for the hot gases from cupolas. F. Schinke, 531,982, 8/27/30.

Core molding machine. Maschinenfabrik Gritzner Akt.-Ges., 531,983, 6/11/30.

Jolt molding machine. Giessereibedarf G. m. b. H., 531,781, 10/17/26.

Process and machine for making hollow bodies by centrifugal casting. Vereinigte Stahlwerke Akt.-Ges., 531,839, 11/1/29.

Casting mold which can be rotated about a vertical axis. J. C. Davis, 531,953, 3/17/23.

Casting machine. R. H. V. Christensen, 528,610, 2/14/29; Denmark 2/29/28 & France 10/9/28.

Process for producing aluminum having high electrical conductivity and great strength. J. Hanco, 531,693, 4/9/29; Belgium 2/19/29.

Process for improving the mechanical properties of aluminum alloys containing copper. Metallges. Akt.-Ges., 531,782, 3/20/24.

Process and device for electroplating large objects in sections, especially with chromium. Siemens & Halske Akt.-Ges., 531,757, 6/20/29; U. S. 6/26/28.

Method of heating tunnel furnaces electrically. Hirsch, Kupfer & Messingwerke Akt.-Ges., 532,000, 11/20/29; Great Britain 11/21/28.

Process for preparing metal blanks for drawing and the like. N. Bregger, 532,244, 12/2/30; Austria 10/17/30.

Process for making iron alloys. I. G. Farbenindustrie Akt.-Ges., 532,409, 6/1/28.

Device for heat treating rock drills. Worthington Pump & Machinery Corp., 532,126, 5/29/26.

Drying oven for foundries. H. Küppers, 532,332 (Addition to 530,985), 1/17/28.

Electrically heated drying oven for foundry cores and the like. E. F. Russ, 532,380, 10/20/29.

Closure for core boxes. W. Freytag, 532,265, 6/26/30.

Method of and device for molding sink basins. Maschinen- u. Werkzeugfabrik Kabel Vogel & Schemann Akt.-Ges., 532,266, 12/25/30.

Process for making approximately pipeless castings from induction furnace charges, and devices used therein. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 532,520, 9/7/26.

Seal for water-cooled centrifugal casting molds. Buderus'sche Eisenwerke, 532,333, 12/5/30.

Process for the simultaneous production of two or more castings by centrifugal casting. G. Pemetzrieder, 532,334 (Addition to 528,881), 4/18/30.

Process for making clean cut castings of refractory metal alloys, such as tungsten carbide. A. Brennecke, 532,169, 10/8/25.

Process and device for making cylinder linings and pistons. T. R. Pawlikowski, 532,267, 3/29/29.

Production of metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 532,534, 3/17/29.

Interchangeable tuyère for cupolas. R. Stotz, *et al.*, 532,710, 7/24/30.

Screening device, particularly for preparing molding sand. Royer Foundry & Machine Co., 532,807, 4/20/30.

Mold for casting the housings of cylinder locks. Firma Albert Küppersbuch, 532,775, 7/1/28.

Process for making bearings. Ges. für elektrische Unternehmungen Ludw. Loewe & Co. Akt.-Ges., 532,808 (Addition to 512,434), 11/2/30.

Press for making steel flasks from seamless pipes. Hütten G. m. b. H., 533,332, 10/13/29.

Process for making a wheel from sheet metal. Budd Wheel Co., 533,124, 2/7/29; U. S. 3/21/28.

Process for diminishing or practically stopping the corrosive action of gases and dilute solutions containing hydrochloric acid on silicon-rich iron alloys. I. G. Farbenindustrie Akt.-Ges., 533,105, 7/9/26.

Carburizing apparatus. The Singer Mfg. Co., 532,882, 9/28/28; U. S. 10/3/27.

Joint between a metal and the metallized surface of a ceramic object. Siemens-Schuckertwerke Akt.-Ges., 533,147 (Addition to 512,976), 5/17/29; U. S. 11/9/28.

Internally heated electric annealing or heating furnace. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 533,448, 1/24/28.

Electric induction furnace. Associated Electrical Industries, Ltd., 533,449, 10/2/29; Great Britain 10/9/28.

Ironless induction furnace. H. Kamps, *et al.*, 533,450, 3/3/29.

Method of butt-welding railroad rails by the electric fusion welding process. Allgemeine Elektricitäts-Ges., 533,149, 8/12/30.

Wire-feed device for electric arc welding machines. Same patentee, 533,150, 1/12/29.

Device for spraying liquids on to ingot molds. W. Schwarz, 532,895, 4/20/30.

Installation for preparing molding sand. M. Chrobog, 533,279, 2/18/28.

Cast car-wheel disk. N. Leonard, 533,280, 12/15/28.

Device for making cores for bearings. Metallges. Akt.-Ges., 532,896, 2/3/27.

Method and device for ejecting bolts from chill molds. O. Junker, 533,281, 8/16/30.

Process for roasting ores in rotary tubular furnaces. Metallges. Akt.-Ges., 532,899, 10/6/28.

Production of metallic tungsten. I. G. Farbenindustrie Akt.-Ges., 532,991, 1/1/30.

Process for the electrolytic production of pure aluminum from alloys of aluminum with less electropositive components. Cie. de Produits Chimiques et Electrométallurgiques Alais, Froges et Carmargue, 533,374, 4/24/28; France 11/9/27.

Process for making electrolytic iron. E. Kelsen, 533,113, 2/9/29; Austria 2/16/28.

Heat treatment of metals and alloys in fused baths containing oxidizable substances. Deutsche Gold- u. Silberscheideanstalt, 532,900, 12/6/29.

Production of high-grade copper alloys. Vereinigte Deutsche Metallwerke Akt.-Ges., 532,992 (Addition to 531,304), 5/13/26.

Process for making very brilliant bronzing powder. E. Oeser, 533,179, 5/8/29.

Process for heat treating sheet metal having a metallic coating. H. Neuhauss, 533,180, 10/26/29.

Method of working rolled material which is to be cold drawn. R. W. Moll, *et al.*, 533,182, 11/28/29.

Production of pipes with internally thickened ends by upsetting. Mannesmannröhrenwerke Akt.-Ges., 532,919, 3/20/30.

Forging machine. O. Georg, 533,410, 3/4/30.

Machine for bending and hardening leaf springs. P. Hobracht, 533,238, 12/15/27.

Device for straightening shafts. Firma Carl Hurth, 532,921, 3/2/30.

Method of brazing hard-metal tips or edges onto steel tools. B. Reinhardt, 533,025, 8/18/29.

Solder. G. Frunhübner, 533,026, 12/30/28.

Soldering iron. A. Weigend, 532,922, 7/6/30.

Process for making cranks and crankshafts which are free from piping and segregation. F. W. Nierhaus, 533,027, 3/16/29.

Strip mill for rolling thin metal strip. Siemens & Halske Akt.-Ges., 533,771, 4/18/29.

Means for braking the device for shifting the rod of pilger mills. E. Röber. 533,682 (Addition to 518,505), 5/17/30.

Rolling mill installation for making seamless pipe. E. Röber, 533,683, 6/5/30.

Liquid brake for the shift rod of pilger rolling mills. E. Röber, 533,684, 3/22/30.

Cylindrical roll with curvilinear concave section. P. Damiron, 533,685, 8/21/29.

Coupling spindle for driving the top roll of rolling mills. Schloemann Akt.-Ges., 533,686, 6/26/30.

Adjusting mechanism for cold rolling mills. W. Bauer, 533,687, 6/28/30.

Runway for cooling beds. F. Klein, 533,662, 2/20/29.

Device for stretching iron bars arriving on a cooling bed. Demag Akt.-Ges., 533,933, 8/28/28.

Entrance-side press for strip mills and auxiliary machines used in the production of metal strip. F. Krupp Grusonwerk Akt.-Ges., 533,934, 7/9/30.

Plate straightening machine. Hydraulik G. m. b. H., 533,663, 5/7/29.

Method of joining pipes to each other and to connections by welding. A. Siebeck, 533,586, 5/16/26.

Means for roughening the surface of a welding electrode which is to be provided with a coating by rolling. Firma Franz H. Stromberg, 533,688, 9/8/29.

Process for making alloys. I. G. Farbenindustrie Akt.-Ges., 533,952, 1/13/27.

Process for forming metallic coatings on elements made of non-conducting oxides, for the indirectly heated cathodes of electric discharge tubes. Allgemeine Elektricitäts-Ges., 533,792, 3/8/27.

Electric melting furnace with roof heating. R. Gautschi, 533,616, 12/3/30.

Arrangement of laminated iron casings for current-carrying coils. Allmänna Svenska Elektriska AB., 533,489, 5/19/29; Sweden 7/16/28.

Means for controlling the power factor of inductively loaded alternating current circuits. Hirsch, Kupfer- u. Messingwerke Akt.-Ges., 533,490, 2/19/28; U. S. 2/25/27.

Induction furnace. Siemens & Halske Akt.-Ges., 533,794, 7/3/26.

Joining electric furnace electrodes. Siemens-Planiawerke Akt.-Ges. für Kohlefabrikate, 533,491, 6/2/27.

Means for automatic regulation of the electrodes of electric furnaces. Cie. des Forges et Aciéries de la Marine & d'Homécourt, 533,492, 12/30/27; France 1/14/27.

Means for utilizing the heat of melting furnaces. Vereinigte Stahlwerke Akt.-Ges., 533,869, 2/1/30.

Method and device for operating cupolas. F. Schinke, 533,922, 11/13/29.

Process and device for making lined melting crucibles. American Machine & Foundry Co., 533,879, 7/19/29.

Process for roasting pyrites. H. Koppers Akt.-Ges., 533,634, 9/25/29.

Reduction of raw materials mixed with solid fuels in rotary tubular furnaces. F. Krupp Grusonwerk Akt.-Ges., 534,011, 4/19/28.

Aluminum alloys which can be improved by thermal and mechanical treatment. Vereinigte Aluminiumwerke Akt.-Ges., 533,635, 8/17/23.

Process for improving aluminum alloys containing up to about 8% zinc. O. Tiedemann, 533,674, 3/5/24.

Method of cooling copper and copper alloy sheet and wire. Akt.-Ges. Brown, Boveri & Cie., 533,636 (Addition to 512,173), 10/15/26.

Process for forming a rust-preventive coating on iron and steel. R. Auerbach, *et al.*, 533,579, 4/8/28.

Process for forming coatings on electrically conducting wire, filaments, strips and the like. Patent-Treuhand-Ges. für elektrische Glühlampen, 533,644, 4/16/30.

Furnace for the simultaneous production of a plurality of soldered joints. Deutsche Industrie-Werke Akt.-Ges., 533,764, 2/2/30.

Process for making heat-exchanging elements, especially out of rustproof steel. F. Krupp Akt.-Ges., 534,014, 8/9/29.

Copying device, especially for torch cutting machines. C. Krebs, 533,995, 4/12/30.

Process for rolling thin, narrow, straight-fibered strips. Heraeus-Vacuumschmelze Akt.-Ges., *et al.*, 534,296, 11/26/29.

Rolling process for making carding wire, starting with round wire. W. Vesper, 534,454, 6/3/28.

Mandrel for tube-rolling mills. Vereinigte Stahlwerke Akt.-Ges., 534,112, 5/22/30.

Electrical control device for the auxiliary machinery of rolling mills. Schloemann Akt.-Ges., 534,208, 1/17/31.

Roller bed with two or more runways placed side by side. F. Krupp Grusonwerk Akt.-Ges., 534,696 (Addition to 491,870), 5/16/30.

Machine for stacking sheets, chiefly for rolling mills. The Bonnot Co., 534,-546, 8/30/29; U. S. 9/19/28.

Cooling device for drawing dies. O. Diener, 534,380, 4/5/30.

Wire-drawing machine. Electrical Research Products, Inc., 534,381, 8/5/27.

Tongs for draw benches. Sundwiger Eisenhütte-Maschinenbau-Akt.-Ges., 534,382, 9/24/30.

Coiling or uncoiling device for strip material. K. Christian, 534,383, 11/-21/30.

Process for making pipes out of sheet metal. K. Breitenbach, 534,547, 1/-19/28.

Extrusion press. Schloemann Akt.-Ges., 534,384, 3/21/30.

Mandrel and plunger guide for horizontal extrusion presses for metals. Adolf Kreuser G. m. b. H., 534,632, 6/17/28.

Mechanically driven extrusion press. F. Singer, 534,633 (Addition to 531,-294), 12/6/27.

Lead-cable press. Hydraulik G. m. b. H., 534,385, 1/6/31.

Tube push bench. Demag Akt.-Ges., 534,386 & 534,387, 2/21/30 & 6/27/30.

Device for corrugating quadrangular tubes for sub-chambered boilers. Press- u. Walzwerk Akt.-Ges., 534,388, 7/4/30.

Process for making finned tubing. Bundy Tubing Co., 534,389, 6/14/28; U. S. 6/20/27.

Tool for making sections out of iron strip. Metallwarenfabrik Wilhelm Schade G. m. b. H., 534,281, 6/15/29.

Rolling mill for rolling rings, particularly car-wheel tires. Adolf Kreuser G. m. b. H., 534,113, 10/21/28.

Process for making carbon electrodes. E. Szarvasy, 534,550, 11/16/26.

Device for removing and carrying off blast-furnace throat dust. Vereinigte Stahlwerke Akt.-Ges., 534,313, 1/29/29.

Sand seal between the throat closure and shaft of blast furnaces. Kölsch-Fölzer-Werke Akt.-Ges., 534,651, 1/31/31.

Process for producing iron. W. Doht, 534,314, 3/15/30.

Process for welding packs of iron or other metals. F. E. Menne, 534,284, 10/28/26.

Cooling device for the door frames of tilting open-hearth furnaces. A. Hütten, 534,285, 8/4/29.

Annealing muffle. Heraeus-Vacuumschmelze Akt.-Ges., 534,623, 5/7/27.

Joint between a metal coating on the oxide layer of a rectifier plate and the conducting lead to the plate. Siemens-Schuckertwerke Akt.-Ges., 534,137, 2/28/29.

Device for soldering seams with a soldering iron connected in the secondary circuit of a transformer. 534,324 (Addition to 523,462), 11/5/30.

High-frequency furnace for heating non-conducting or poorly conducting materials. E. J. Kohlmeyer, 534,492, 4/6/29.

Rotary forehearth for cupolas. Gewerkschaft Zuversicht VIII, 534,575, 6/3/30.

Process for working up preheated materials which give off volatile metals when heated strongly in a furnace. F. Krupp Grusonwerk Akt.-Ges., 534,094, 7/17/27.

Utilization of aluminum-chromium alloys. K. Schmidt G. m. b. H., 534,376, 6/8/24.

Continuous striking mechanism. Meier & Weichelt, 534,156, 4/2/30.

Fatigue testing machine. Schumag Schumacher Metallwerke Akt.-Ges., 534,157, 4/26/29.

Fatigue bending machine for the simultaneous testing of several similar specimens. Maschinenfabrik Augsburg-Nürnberg Akt.-Ges., 534,675, 8/-27/30.

Method of determining the direction and magnitude of the surface stresses in structural elements. Maybach-Motorenbau G. m. b. H., 534,158, 12/-21/26.

Device for producing sheets and tubing (by electroforming). E. Kelsen, 534,602, 6/22/29; Austria 6/27/28.

Machine for branning or degreasing tin plate. S. Davies, 534,603, 3/12/29; Great Britain 9/5/28.

Process for lead-coating metal objects. American Machine & Foundry Co., 534,604, 7/5/28.

Process for converting molten metals, salts and the like into products having a uniform granular, especially spheroidal form. I. G. Farbenindustrie Akt.-Ges., 534,681, 2/13/30.

Swedish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Electric resistance welding apparatus. F. H. Leslie, 72,495, 4/9/26, Priority date 4/11/25.

Combined electric heat-radiation and charge-resistance furnace. A/S per Kure, Norske Motor & Dynamofabrik, 72,496, 6/20/28.

Holder for electric furnace electrodes. Siemens-Planiawerke Akt.-Ges. für Kohlefabrikate, 72,497, 12/15/28, Priority date 5/4/28.

Electric spot welding device. Allgemeine Elektricitäts Ges., 72,299, 9/20/29, Priority date 10/3/28.

Process for making plates and fittings for use in cellulose manufacture, and elements thus produced. J. Härdén, 72,509, 4/12/29.

Process and device for casting molten metal under pressure. R. H. V. Christensen, 72,615, 2/1/29, Priority dates 2/29/28 & 10/9/28.

Method of protecting metals against corrosion during treatment with pickling or coating agents. C. F. Boehringer & Söhne G. m. b. H., 72,624, 5/19/30, Priority date 5/21/29.

Means for rotating gears which are being hardened inside hardening boxes. F. Klopp, 72,607, 11/21/29.

Process for providing printing plates or printing surfaces with a surface which is easily separable from the matrix. Internationale Tiefdruck G. m. b. H., 72,623, 5/7/30.

Process for the production of metals and metallic compounds. A. S. Burman, *et al.*, 72,643, 6/25/29.

Process for freeing aluminum-bearing material from iron and other substances. A. S. Burman, *et al.*, 72,644, 11/11/29.

Process for producing metallic compounds or metals. A. S. Burman, *et al.*, 72,645, 2/17/30.

Process for producing metalloids or metalloidal or metallic compounds in the form of rods. V. Kjellgren, 72,659, 5/17/27.

Process and machine for expanding metal tubing. Mannesmannröhren-Werke, 72,685, 6/30/27.

Process for making wrought iron. A. M. Byers Co., 72,694, 6/19/29, Priority date 7/19/28.

Process for treating pyrite ores. S. I. Levy, *et al.*, 72,709, 2/28/30.

Fusion electrolysis process. J. B. Stålhane, 72,710, 1/16/30.

Current lead-in device for electric furnace electrodes. Norske A/S for elektrokemisk Industri, 72,752, 9/21/26, Priority dates 9/30/25 & 12/9/25.

Heat recuperator with refractory hollow blocks. K. Kniepert, 72,803, 1/31/30; Priority date 2/13/29.

Iron alloy. B. D. Saklatwalla, 72,804, 5/4/28; Priority date 6/30/27.

Means for protecting water-cooled mercury rectifiers made of iron, against corrosion. Fusi Denki Seizo K.K., 72,816, 2/7/30; Priority date 2/27/30.

Electric induction furnace. Finspongs Metallverk AB., 72,817, 10/20/27.

Process for protecting magnesium and its alloys against corrosion by hot baths of fused salts. I. G. Farbenindustrie Akt.-Ges., 72,827, 11/15/30; Priority date 12/11/29.

Process for producing pure alumina. Zaidan Hojin Rikagu Kenkayujo, 72,857, 7/11/27.

Process for reducing ores without melting. A. Johnson & Co., 72,860, 12/-10/28.

Method of operating mechanical roasting furnaces and devices used therewith. A. V. Carlson, 72,877, 4/25/27.

Process for producing alkali metals by fusion electrolysis. J. B. Stålhane, 72,878, 2/4/30.

Process for pickling metals. J. H. Gravell, 72,884, 3/27/28; Priority date 3/29/27.

Process for producing iron from iron-bearing ores. Vereinigte Stahlwerke Akt.-Ges., 72,900, 1/20/28; Priority date 2/7/27.

Two-piece chaplet. E. Sonnet, 72,971, 8/2/29.

Process for producing zinc. H. E. Coley, 72,974, 1/10/28; Priority date 2/2/27.

Process and machine for making welded tubing, especially precision tubing. Vereinigte Oberschlesische Hüttenwerke Akt.-Ges., 73,005, 1/21/30; Priority date 2/1/29.

Swiss Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Method and means for connecting and disconnecting condensers in high-frequency circuits, especially those supplying induction furnaces. Allgemeine Elektricitäts Gesellschaft, 146,699, 3/8/30; Germany 3/13/29.

Zinc alloy. The New Jersey Zinc Co., 146,911, 8/23/29; U. S. 3/12/29.

Process for preparing magnesium. L. Friedrich, 146,912, 4/16/20.

Device for winding thin metal strip on tubular reels. W. Bauer, 146,913, 2/-6/30.

Device for driving coiling reels for cold rolling mills. W. Bauer, 146,914, 2/-6/30.

Device for straightening strips to be cold rolled. W. Bauer, 146,915, 2/6/30.

Process for improving the corrosion resistance of aluminum sheet and strip. Vereinigte Silberhammerwerke Hetzel & Co., 146,916, 4/7/30.

Process for aluminothermic welding. Elektro Thermit G. m. b. H., 146,917, 3/21/30; Germany 4/17/29.

Welding machine. Ford Motor Co., Ltd., 146,918, 5/22/30; U. S. 5/25/29.

Process for making coated metal strip. The Cold Metal Process Co., 146,919, 2/19/30; U. S. 12/19/29.

Process for cleaning and brightening the surface of metals. The Bullard Co., 147,172, 3/24/30.

Method and instrument for determining high temperatures. K. Weisert, 147,-191, 5/27/30.

Process for preparing permanent molds for casting magnesium and magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 147,205, 7/15/30; Germany 8/10/29.

Drive for template-guided tools. A. Schmidt, 147,206, 4/4/30; Austria 4/-9/29, 9/11/29 & 11/17/29.

Electric welding machine. Ford Motor Co., Ltd., 147,207, 6/12/30; U. S. 6/20/29.

Plate straightening machine. F. Ungerer, 147,208, 7/23/29.

Method of charging a closed electric electrode furnace. P. L. J. Miguet, *et al.*, 147,272, 10/17/29; France 12/6/28.

Salt-bath furnace. Siemens-Schuckertwerke Akt.-Ges., 147,273, 7/11/30; Germany 8/24/29.

Process for metallizing objects of organic origin by means of metal vapor. K. Richter, 147,473, 6/2/30.

Process for improving the mechanical properties and structure of aluminum-silicon alloy castings. Aluminium-Industrie Akt.-Ges., 147,516, 3/-11/30.

Process for soldering metal parts. N. V. Philips' Gloeilampenfabrieken, 147,517, 3/28/30; Netherlands 4/27/29.

Process for dispersion hardening of shaped object, particularly castings of magnesium alloys. I. G. Farbenindustrie Akt.-Ges., 147,522, 3/11/30; Germany 4/25/29.

Process for improving the mechanical properties of magnesium alloys. Same patentee, 147,523, 5/19/30; Germany 6/29/29.

Process for coloring metal foil. Folien Akt.-Ges. Arbon, 147,530, 2/5/30.

Magnetizable pulverized-metal core. Hartstoff-Metall Akt.-Ges. Hametag, 147,589, 4/9/30.

Protective device for electric furnace electrodes. Siemens & Halske Akt.-Ges., 147,596, 4/22/30; Germany 5/31/29.

Process for making carbon electrodes for electric furnaces. Siemens Planiawerke Akt.-Ges. für Kohlefabrikate, 147,597, 5/17/30; Germany 11/-23/29.

Process for forming aluminum coatings on metals. Aluminium Industrie Akt.-Ges., 147,807, 7/9/30; Germany 8/24/29.

Machine for casting curved stereotype plates. Wood Newspaper Machinery Corp., 147,813, 7/25/29.

Process for refining magnesium-cerium alloys. I. G. Farbenindustrie Akt.-Ges., 147,862, 3/13/30; Germany 4/15/29.

Process for making gas- and oxide-free ingots and castings. A. Godefroid, 147,863, 7/7/30.

Process for making metal shapes. H. Seiferth, 147,864, 5/19/30; Germany 6/27/29.

Welding or soldering flux, particularly for aluminum, and process for making the same. O. Asal, 147,865, 5/16/30.

Process for making tools. F. Krupp Akt.-Ges., 147,866, 6/10/30; Germany 11/6/29.

Soldering flux for aluminum, copper, brass, iron, etc. F. Badertscher, 147,867, 12/31/30.

Process for making products having improved properties out of magnesium and its alloys. I. G. Farbenindustrie Akt.-Ges., 147,868, 1/25/30; Germany 3/11/29.

Process for making shapes having uniform wall thickness out of strips of sheet metal. Same patentee, 147,869, 9/6/29; Germany 10/3/29.

Process for making vessels of polyhedral shape, such as ice cells, out of tough metallic material. F. Krupp Akt.-Ges., 147,870, 5/30/30; Germany 6/6/29.

Surface-hardened shaft journal. Deutsche Edelstahlwerke Akt.-Ges., 147,-872, 5/9/30; Germany 5/14/29.

Process for bright-annealing metals in an electric annealing furnace. Siemens-Schuckertwerke Akt.-Ges., 147,938, 8/15/30; Germany 12/21/29.

Patent attorney, chemical engineer, now in charge of patent department Eastern manufacturer, offers part time services to firm or corporation. Box PA1, Metals & Alloys, 3619 Forbes St., Pittsburgh, Pa.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

1101 **Steel.**—The Hawkridge Brothers Company is prepared to furnish steel of every description and has issued a stock list showing the sizes in which it is possible to obtain their tool steels, spring steels, cold drawn steels and special purpose steels.

1102 **Finishing Compounds.**—The Carborundum Company, Niagara Falls, N. Y., has directed its research and resources toward the development of a suitable finishing compound and also to a close study of proper applications and the procuring of scientifically correct results. The result of this research is presented in a booklet prepared by them.

1103 **Welding Rod.**—Bronze welding is generally used to unite parts made of cast iron, malleable iron and steel, but it may be applied to almost all commercial metals, ferrous and non-ferrous. Revere Copper and Brass Inc., New York, have issued a booklet telling about their Roman Bronze welding rod, and illustrating some of its uses.

1104 **Heat and Corrosion Resistant Alloys.**—An attractive pamphlet has recently been sent out by the Michiana Products Corporation, Michigan City, Ind., which gives technical data on their "fire armor," "Zorite," "No. 48 alloy" and "Nirosta alloys." The physical properties of each of these are given and conditions under which its use is suitable.

1105 **Nitralloy.**—A leaflet prepared by The Nitralloy Corporation, 230 Park Ave., New York City, gives a partial list of reported successful applications for Nitralloy.

1106 **Heat Treating Containers.**—The Rezistal Lite-Wate heat-treating containers are lighter in weight, which makes possible a lower operating cost and a reduction in fuel costs. The Pressed Steel Co., Wilkes-Barre, Pa., have sent out two leaflets describing and illustrating these containers.

1107 **Die Steel.**—A new type of high-carbon-high chromium die steel has been developed by the Firth-Sterling Steel Co., 410 New Park Ave., Hartford, Conn. They have called it "Cromovan" triple die steel and have compiled a booklet describing its special properties, giving the heat treatment recommended for it and method to be used when pack hardening.

1108 **Screw Steel.**—Union Supercut, a new screw steel, is a product of the Bessemer converter, and of very similar analysis to Bessemer Steel. It is said to have superior machining qualities and exceptional finished parts. A small booklet sent out by the Union Drawn Steel Co., Beaver Falls, Pa., reproduces set-up sheets which represent actual results obtained in plants.

1109 **Potentiometer Pyrometer.**—A new booklet issued by the Brown Instrument Company, Philadelphia, Pa., explains and illustrates the principal features of their new potentiometer pyrometer with special reference to accuracy of operation and ruggedness in service.

1110 **Stainless Steels.**—An attrative black and silver broadside sent out by the Illinois Steel and Carnegie Steel Companies lists a number of typical uses for their products.

1111 **Chemicals.**—The Dow Chemical Co., Midland, Mich., has issued a leaflet containing a list of the chemicals prepared by them.

1112 **Electric Furnaces.**—The various types of electric furnaces manufactured by the General Electric Co., Schenectady, N. Y., are illustrated and described in a twenty-four page book prepared by them.

1113 **Welded Steel Gears.**—The research department of Lukenweld, Inc., has prepared a pamphlet on "Welded Steel Gears from Blanks of Lukenweld Construction" which shows the development of these gears and their special properties.

1114 **Fahrite.**—An interesting booklet with this title describes the plan of the Ohio Steel Foundry Company, Springfield, Ohio, and illustrates castings for a variety of industries. Fahrite alloy castings are said to be immune to the action of high sulphur gases and the fumes of zinc, lead, antimony or any other products of ordinary roasting operations.

1115 **Nitriding.**—Bulletin 950 of the Leeds & Northrup Co., Philadelphia, Pa., describes the Homo method applied to nitriding of steel and shows typical installations of their furnaces. A price list is included.

1116 **Steel-Service.**—Joseph T. Ryerson & Son, Inc., Chicago, Ill., will cut heavy plates and billets in any irregular shape or size and have recently sent out a bulletin illustrating some of the unusual forms and shapes they have cut.

1117 **81 Years of Iron and Steel.**—An interesting little booklet has been issued by the Jones & Laughlin Steel Corporation, Pittsburgh, Pa. It gives a short historical sketch of the company and has many illustrations of the various departments and plants of the company.

1118 **Ludlum Products.**—The various products of the Ludlum Steel Company, Watervliet, N. Y., are listed in a bulletin sent out by the company lately.

1119 **Electric Melting Pots.**—Bulletin TC-11 of the Harold E. Trent Co., Philadelphia, Pa., is a catalog of their electric melting pots for melting Babbitt, solder, tin type metal and lead for continuous service and temperatures up to 1000° F.

1120 **Coloring Copper and Brass.**—The Copper & Brass Research Association, New York City, has issued a small bulletin containing a few simple formulae for cleaning and coloring copper and brass. The formulae are ones which have been widely used.

1121 **Lead.**—The September issue of this publication of the Lead Industries Association, Graybar Bldg., New York, N. Y., features several interesting and unusual uses of lead.

1122 **Heat Treating Furnaces.**—Leaflet No. 295 sent out by the W. S Rockwell Co., 50 Church St., New York City, illustrates their heat-treating and carburizing furnaces of the enclosed front type for annealing, hardening, normalizing, drawing, etc. These may be either fuel or electric fired.

1123 **Strain Gage.**—The Tuckerman optical strain gage for the precise measurement of tension and compression strains in hot and cold metal specimens and for the testing of riveted joints is discussed in a pamphlet sent out by the American Instrument Co., Inc., 774 Girard St., N. W., Washington, D. C.

1124 **Arc Welders.**—General Electric Company leaflet GEA-1440 is devoted to their arc welders, both portable and stationary. A number of these are described and some suggestions for their operation are given. The leaflet is punched for binding in the G-E folder. Other leaflets by the same company are: GEA-1450, Mechanical-Drive Turbines; GEA-137B, Low-Speed Synchronous Motors; GEA-1406, Single-Phase Motors.

1125 **High Speed Steel.**—A new booklet of the Firth-Sterling Steel Company discusses two of their high speed steels—Circle C and Blue Chip. Each of these is discussed at length and performance data are included. There are also some recommendations as to heat treatment.

1126 **Pot Furnaces.**—Bulletin No. 10 of the American Electric Furnace Company of Boston is devoted to their cylindrical type pot furnaces for lead, salt and cyanide. A cross section diagram of one of the furnaces is shown.

1127 **Welding.**—The September issue of Oxy-Acetylene Tips, published by the Linde Air Products Co., 30 East 42nd St., New York City, features an article on the use of welding for pipe line construction.

1128 **Dowmetal.**—This is the name which identifies magnesium alloys developed and manufactured by the Dow Chemical Company, Midland, Mich., and they have recently sent out a small booklet which gives the properties and applications of these alloys.

1129 **Plating Rolled Zinc and Zinc Die Castings.**—A research bulletin issued by the New Jersey Zinc Company, 160 Front St., N. Y., assembles the information necessary for the practical plating of rolled zinc and die cast zinc parts. It is also possible to obtain a chart giving the procedure in diagrammatic form.

1130 **Sturaco.**—Bulletin No. 2 published by the D. A. Stuart & Co., Chicago, Ill., gives the development of their gear lubricant, "Sturaco." It is fully illustrated.

1131 **Furnace Control.**—Circulars introducing the Isley furnace control with automatic reversing and perfect regulation for all types of regenerative furnaces have been sent out by the Morgan Construction Co., Worcester, Mass.

1132 **Testing.**—A leaflet sent out by the American Instrument Co., Inc., Washington, D. C., describes a method for the study of the casting qualities of metals which was developed at the Bureau of Standards.

1133 **Compressors.**—The Spencer Turbine Co., Hartford, Conn., has prepared a pamphlet describing their slow speed compressors. A cross-section of one of the compressors is shown and charts giving performance data are included.

1134 **Arc Welding.**—Bulletin GEA-995B of the General Electric Company, Schenectady, N. Y., is a 40-page booklet devoted to arc welding in industry. Applications of welding to industrial uses are discussed and profusely illustrated. Bulletin GEA-1477 gives characteristics of the new G-E arc welders.

1135 **Metals and Alloys.**—A leaflet listing their products and describing their service has just been issued by the Electro Metallurgical Company, 30 East 42nd St., New York, N. Y.

1136 **Conveyor Belts.**—A new loose-leaf handbook describing in detail the various types of metal conveyor belts for high and low temperatures has been prepared by the Wickwire Spencer Steel Co., 41 East 42nd St., New York, N. Y. The company plans to issue new pages on additional features that are added to their line.

1137 **Furnaces.**—Bulletin No. 296 of the W. S. Rockwell Co., 50 Church St., New York, N. Y., describes their rotary carburizing furnaces, both electric and fuel fired. Their bulletin No. 289 discusses their counterflow and straight line type continuous furnaces.

1138 **Industrial Machinery.**—Machinery for tumbling, separating, cleaning, washing, burnishing, painting or pickling metal parts is illustrated in a recent catalog of the Ideal Industrial Machinery, Winton Place, Cincinnati, Ohio.

1139 **Drilling.**—Whitman & Barnes, Inc., Detroit, Mich., have sent out several leaflets lately. One of these is "How to Drill High Manganese Steel" and others describe their high speed drills, their wire drills and their interchangeable punches and retainers.

1140 **Copper and Brass Products.**—Many copper, brass and bronze products are listed in the July 1, 1931 catalog of Revere Copper and Brass, Inc., 230 Park Ave., New York, N. Y. Prices are included.

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Sixty section editors and abstractors cover over 400 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstracts appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important. An improvement we hope to make in the METALLURGICAL ABSTRACTS in the near future is the cross-indexing of articles, which belong under several sections. Some of the sections are descriptive and some are self-explanatory and we have so labeled them.

CLASSIFICATIONS

0 (General). Under this heading we classify all abstracts which are of interest to the metallurgical industry in general. Compare this with Section 20—miscellaneous.

1, 2, 3 (Properties of Metals, Non-Ferrous and Ferrous Alloys). An article goes under one of these heads when the properties are emphasized and not the method of determining them.

4 (Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys). This takes articles on weather resistance, resistance to acids, etc., and protection against them.

5a (Structure of Metals & Alloys—Metallography & Macrography). An article would go in this group if it discussed the microscopic or macroscopic study of metals and alloys, or the determination of constitutional diagrams, critical points, etc.

5b (Structure of Metals & Alloys—Structure and X-Ray Analysis). This group includes articles dealing with the structure of metals and alloys as determined by X-ray analysis and X-ray examination.

6 (Physical, Mechanical & Magnetic Testing). If an article emphasizes the method of determining the properties of metals rather than the properties them-

selves it belongs in this section. The abstracts on fatigue appearing under this section are prepared with the coöperation of the Fatigue Research Committee of the American Society for Testing Materials.

7a (Electro-Chemistry—Electroplating). This will include articles on the electrolytic plating of metals.

7b (Electro-Chemistry—Electrometallurgy). This relates to the electrolytic recovery and refining of metals.

8 (Metallic Coatings Other than Electroplating). Articles on galvanizing, metal spraying or dip coating would come in this group.

9 (Industrial Uses and Applications). If the application of the metal is stressed rather than the properties the article belongs in this section.

10 (Heat Treatment). If heat treatment in general is discussed the article would be classed under section 10; if, however, any distinct operation is stressed it would go under the corresponding subhead.

11 (Joining of Metals and Alloys). The explanation for this group is similar to that for section 10.

12 (Working of Metals & Alloys). We feel that the divisions in this group are self-explanatory to men in the metals industries. We might say, though, that an article is classified under 12j (Cold Working) only when it will not fit under one of the other heads—for instance, an article on cold rolling would be put under 12c, rolling.

13 (Defects). This section includes articles dealing with inclusions, segregations, cracks, pinholes, blowholes and failures.

14 (Chemical Analysis). If the method of analysis is emphasized the article goes here.

15 (Historical & Biographical). Self-explanatory.

16 (Economic). Articles in this group are devoted to economic trends, savings, cost estimates, etc.

17 (Plants & Laboratories) This section includes descriptive articles.

18 (Machinery & Supplies). This includes descriptive articles.

19 (Bibliographies). Self-explanatory.

20 (Miscellaneous). This takes in all scattered articles which do not belong anywhere else.

21 (Laboratory Apparatus). Purely descriptive articles belong here. If results or processes are given they would go under 6 or 14.

22 (Foundry Practice & Appliances). This is self-explanatory.

23 (Furnaces & Fuels). This takes in descriptive articles. Otherwise they go under 10, heat treating, 10b, annealing, etc.

24 (Refractories & Furnace Materials). This section is hand-in-hand with 23. Furnace men should read both of them.

25 (Gases in Metals). This is self-explanatory.

26 (Inspection). This includes articles dealing with inspection, pure and simple—not X-ray or microscopic analysis.

27 (Effects of Elements on Metals and Alloys). Articles dealing with the effect of the addition of different chemical elements to metals and alloys are included in this group.

28 (Instruments & Controllers). Descriptive.

29 (Effect of Temperature on Metals and Alloys). This section is prepared in conjunction with the Joint High Temperature Committee of the A. S. T. M. and the A. S. M. E.

30 (Leaching). Self-explanatory.

31 (Reduction Metallurgy). This would include articles on blast furnace practice.

32 (Non-metallic Coatings for Metals and Alloys). Articles discussing painting, enameling, lacquering, etc., belong here.

◆ ◆ ◆ ◆ ◆

It has been our purpose in this outline to make our scheme of classification apparent to our readers and so, perhaps, make the abstract section more useful. If you have any questions pertaining in any way to the abstracts, write to us. We shall be glad to answer them in detail.

The classification number at the end of each abstract will be of assistance in mounting them on file cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

PROPERTIES OF METALS (1)

Change in the Electrical Resistance of Nickel Wire on Straining at Raised Temperature. (Veränderung des Widerstandes von Nickeldraht beim Spannen mit gleichzeitiger Erwärmung.) S. ARZIBYSCHEW & W. J. U. JUSCHAKOW. *Zeitschrift für Physik*, Vol. 64, 1930, pages 405–410.

Measurements of the electrical resistance of a nickel wire subjected to tensile stress show that stress at first causes a decrease of electrical resistance and that the value progressively decreases to a minimum and subsequently commences to rise. The effect produced varies with temperature and disappears entirely at the Curie point. It is, therefore, considered that the change in electrical resistance of the strained nickel wire is definitely associated with its ferromagnetic properties. Ha(1)

The Isotopic Constitution and Atomic Weights of Selenium, Bromine, Boron, Tungsten, Antimony, Osmium, Ruthenium, Tellurium, Germanium, Rhenium and Chlorine. F. W. ASTON. *Proceedings of the Royal Society*, Vol. A-132, Aug. 1931, pages 487–498.

Amended Table of Isotopes

Element	Atomic Weight	Atomic Number	Minimum Number of Isotopes	Mass numbers of isotopes in order of abundance
Ru	101.7	44	7	102, 101, 104, 100, 99, 96, 98
Te	127.5	52	4	128, 130, 126, 125
W	184.0	74	4	184, 186, 182, 183
Re	186.31	75	2	187, 185
Os	190.8	76	6	192, 190, 189, 188, 186, 187

WAT(1)

Cold Working Properties of Tantalum. M. M. AUSTIN. *Metal Stampings*, Vol. 3, Mar. 1930, pages 247–248.

See *Metals & Alloys*, Vol. 2, June 1931, page 109. (1)

The Magnetization of Nickel Wire under Severe Tensile Stress. (Die Magnetisierung von Nickeldraht unter starkem Zug.) R. BECKER & M. KERSTEN. *Zeitschrift für Physik*, Vol. 64, 1930, pages 660–681.

The influence of elastic distortion on magnetic susceptibility has been quantitatively determined on samples of nickel wire subjected to severe tensile stress. The results are presented in detail, and theoretically discussed. Ha(1)

The Annealing of Hard Conductor Aluminum. (Ueber das Anlassen von hartem Leitaluminium.) H. BOHNER. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July–Aug. 1931, pages 280–283.

The effect of different annealing temperatures and annealing times on tensile strength and electric conductivity of hard drawn Al wires of at least 99.5% purity is investigated and is compared with the results of other investigations on less pure Al. It can be stated that, as a practical result, a conductivity of 36 ohms/m./mm.^{2} at 20° C. can be obtained easily with a tensile strength of 18 kg./mm.^{2} Ha(1)

On the Toxicity of Aluminum as Compared with Iron, Nickel and Other Metals. (Sur la toxicité de l'aluminium, comparée á celle du nickel et d'autres métaux.) GEGRIEL BERTRAND & P. SERBESCU. *Comptes Rendus*, Vol. 193, July 20, 1931, pages 128–131.

As the result of experiments with cooking vessels of various metals, the authors arrived at the conclusion that, in the absence of proof to the contrary, it seems that the fear of the noxious action of small quantities of Al artificially introduced in alimentary substances has no foundation—at least so long as the quantities remain of an order similar to those which exist in the normal state in the tissues of animals and plants. OWE(1)

Preparation of Pure Cerium. (Préparation of cérium pur.) MAURICE BILLY & FELIX TROMBE. *Comptes Rendus*, Vol. 193, Sept. 7, 1931, pages 421–423.

An electrolytic method of producing Ce is described, the bath being composed of cerium chloride, potassium chloride and calcium fluoride in suitable proportions. The bath is maintained at a temperature of 850° C. and the Ce deposited contains only traces of Si. The following properties are quoted for the metal: Brinell hardness (250 kg., 5 mm. ball), 42.5; density, 6.75; melting point, 815 ± 5° C. OWE(1)

On the Magnetic Properties of Metals (Copper, Silver and Alkali Group). FRANCIS BITTER. *Physical Review*, Vol. 36, Series 2, 1931, pages 978–983.

The magnetic susceptibility of Cu and Ag is affected by structure factors; annealing increases the diamagnetism and drawing decreases it. The Ag used in the experiments was pure and diamagnetic but the Cu was slightly paramagnetic owing to impurity, and became more paramagnetic on drawing. The wide divergencies between the published figures for the susceptibility of the alkali metals are pointed out, and may be due to structure effects. The specific susceptibility of Li is measured as 3.8×10^{-6}. There is a wide discrepancy between the observed susceptibilities of the alkali metals and those calculated for the free electrons by the Pauli theory, together with the diamagnetic contributions of the ions, and it is suggested that the effects of partly bound electrons should be considered. 13 references. Ha(1)

The Resistance of Ferro-Magnetic Metals as a Function of Temperature. (Die Temperaturabhängigkeit des Widerstandes ferromagnetischer Metalle.) G. BORELIUS. *Annalen der Physik*, Vol. 8, No. 3, 1931, pages 261–266.

On the basis of the relations already discovered between resistance and spontaneous magnetization, it is shown (using nickel as an example) that the electric resistance of a ferromagnetic metal can be considered to be the sum of a normal temperature resistance and an additional resistance which is a function of the magnetization. Compressibility and Pressure Coefficient of Resistance, Including Single Crystal Magnesium. P. W. BRIDGMAN. *Proceedings American Academy Arts & Sciences*, Vol. 66, Mar. 1931, pages 255–271.

Measurements of compressibility at 30° and 75° C. are reported on 10 materials. All except metallic Mg crystallize in the cubic system so that measurements were made on crystal aggregates. Mg crystallizes in the hexagonal system and single crystals were prepared and the compressibility was measured parallel and perpendicular to the axis. The materials measured were NaF, BaF_2, SrF_2, CdF_2, AlSb, CdTe, HgTe, TiN, TiC and Mg. The effect of pressure on the electric resistance was measured for TiN, TiC and Mg. Ha(1)

Note on Theory of Internal Friction in Metals. E. M. HORSBURGH. *Transactions Institution Engineers and Shipbuilders in Scotland*, Vol. 72, Yearbook 1929, pages 496–509.

A mathematical expression of the stresses occurring in metals as they approach failure. Tensile and compressive stresses are masked by shear and sliding. Internal friction in metals assists them to resist failure. WHB(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Properties of Rolled and Drawn Silicon-Manganese-Copper Alloys. E. VOCE. *Rolling Mill Journal*, Vol. 5, Jan. 1931, page 26.

Crystallization Experiments under 20,000 Atmospheres Pressure. (Kristallisationsversuche bei Drucken bis zu 20,000 Atmosphären.) GEORG WELTER. *Metallwirtschaft*, Vol. 10, June 12, 1931, pages 475–481.

Contains 5 references. A series of Al alloys were melted and poured in a metal mold which was placed into a hydraulic press. While the alloy was solidifying, pressure of 12,000 to 20,000 atmospheres was applied to the top of the metal. By this process the tensile strength was increased 30 to 40% over alloys cast in metal molds without pressure. The elongation, hardness and specific gravity were also considerably increased. Macrographs of the fracture and photomicrographs of the structure of the alloys cast with and without pressure are given to show the very much smaller crystals formed under pressure. They have the appearance of heat treated alloy steel, and are entirely free from porosity, cracks and segregations. Tests made with and without an asbestos lining around the mold gave identical results proving that the increase in strength was due to pressure and not quicker cooling. A series of Al alloys containing 13 to 21% Si was cast under pressures of 2000 to 20,000 atmospheres and examined microscopically. It was found that the eutectic, which under ordinary pressure is at 12% Si, was changed to 15% at 12,000–13,000 atmospheres and to 17–18% at 18,000–20,000 atmospheres. At 12,000 atmospheres the solid solution contained 3% Si against 1.5% at ordinary pressure. Test bars of three alloys subjected to 9000 atmospheres in a bath of molten lead at 550° C. showed no increase in strength or hardness. CEM(2)

Three Lectures on Dental Alloys. WALTER ROSENHAIN. Dental Board of the United Kingdom, London. Cloth, 6 × 9½ inches, 72 pages. Price 5 shillings.

Three lectures by Dr. Rosenhain arranged by the Dental Board to further post-graduate study, and delivered in 1926, were brought together into one volume. The object which has been kept in view has been not so much to give detailed information, but rather to show what important results must follow when modern metallurgical methods are applied to the particular metals and alloys employed in dental practice.

The first lecture, pages 1 to 26, deals with the structure and constitution of pure metals and alloys in quite an elementary manner. Microphotographs have been used abundantly to illustrate typical structural phases. Binary and ternary equilibrium diagrams are developed to illustrate systems common to alloys of definite dental interest.

In the second lecture, pages 27 to 56, the physical properties of the gold-silver-copper alloys, the silver and tin amalgams, the silver-tin alloys and the silver-tin-mercury alloys are discussed more elaborately. The investigations on the amalgams and silver-tin alloys have been carried out more or less completely at the National Physical Laboratory.

The lecturer throws doubt on the interpretation and accuracy of the silver-tin-mercury system as given by Joyner and Knight. The behavior of silver-tin filings on aging is discussed and two possible explanations for the setting of amalgams are offered. An interesting description is given of the method used by the National Physical Laboratory for studying the structure and constitution of mercury and amalgams.

The third lecture, pages 57 to 72, covers the treatment of metals and alloys by casting, rolling, pressing and swaging. The importance of removing gases from molten metal, the plasticity of metals and the effect of cold work and heat-treatment on the crystal structure of dental alloys are given considerable attention.—C. H. Lorig (2)-B-

Properties of Lead-Bismuth, Lead-Tin, Type Metal and Fusible Alloys. J. G. THOMPSON. *Metal Industry*, London, Vol. 39, July 3, 1931, pages 7–10, July 10, 1931, pages 33–34.

Condensed from Research Paper No. 248 of the U. S Bureau of Standards. The tensile properties and hardness of the above four types of lead alloys are given. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 29. PRK(2)

Nickel-Copper Alloys of High Elastic Limit. D. G. JONES, L. B. PFEIL & W. T. GRIFFITHS (Mond Nickel Co.). *Institute of Metals, Advance Copy* No. 573, Sept. 1931, 18 pages.

Alloys containing up to 50% Ni were tested. In preparing the alloys small quantities of Mn, Si and Mg were added as "deoxidizers." Low elastic-limit or proportional-limit values were obtained in both annealed and cold rolled alloys. A high elastic limit could be produced by any of the following 3 methods: (1) annealing the cold rolled alloy at a low temperature (400–550° C.); (2) adding Si to the alloy in a quantity dependent on the Cu-Ni ratio and hardening by quenching from 800–900° C. and aging at 500–550° C.; (3) combination of the first 2 methods. As an example of the properties produced by this last treatment, an 80–20 Cu-Ni alloy containing 0.17% Si and 1.26% Mn cooled rapidly from 900° C., cold worked to a reduction of 50% and reheated to 550° C. for 1 hour had the following tensile properties: 42.2 tons/in.^{2} tensile strength, 27.6 tons/in.^{2} elastic limit and an elongation in 2 in. of 21%. 2 references. JLG(2)

Studies on Light Alloys. (Contributo alla conoscenza di alcune leghe leggere.) LUIGI LOSANA. *L'Industria Chimica*, Vol. 5, Feb. 1930, pages 145–150.

The coefficient of thermal expansion, heat conductivity, and specific heat at various temperatures of a number of Al-Si, and Al-Mg alloys have been measured. The equilibrium curves are shown. The following conclusions are drawn: the coefficient of expansion of Al-Si alloys up to 500° decreases with increasing Si; Mg-Al alloys show a similar decrease with increasing Al; the heat conductivity of Al-Si alloys decreases with increasing Si, a very large drop is noted with 0–1% Si; Mg-Al alloys show decreases when small amounts of Al are added to Mg and vice versa, with a sudden jump at about 55% Mg, corresponding to Al_2Mg_3 (electrical conductivity shows a similar phenomenon); specific heats decrease rapidly with increased Si, while with Mg-Al, there is a rapid drop with increased Al up to 20% Al, then increases slowly to 60% Mg, then drops gradually. This maximum is most noticeable at lower temperatures. WHB(2)

The Alloys of Aluminum. (Les alliages d'aluminium.) H. GODFROID. *La Revue de Fonderie Moderne*, Vol. 24, Sept. 10, 1930, pages 301–302, 315–318 343–346.

The use of light alloys and their advantages over steel, their classification and the physical properties of Cu, Al, Mg, Ca and Na are given. The production and properties of Al and the properties of its alloys with Cu and other metals; Zn, Sn, Mg, Ni and Ti, are described. The design of molds suitable for Al alloy casting, the use of special Al alloys, and a comparison of the mechanical and electrical properties of commercial Al-Cu and Al steels are discussed. (2)

Some Properties of Some Alloys of Precious Metals. (Proprietá delle leghe da Oreficeria.) ADELAIDE LABO. *L' Industria Chimica*, Vol. 5, May 1930, pages 571–573.

The composition, hardness and tensile strength of gold from 9–22 carats is given. WHB(2)

Age-hardening Copper-titanium Alloys. F. R. Hensel & E. I. Larsen. *American Institute Mining & Metallurgical Engineers, Technical Publication*, No. 432, Sept. 1931, 11 pages.

Cu-Ti alloys containing up to 25% Ti were prepared. Those containing 5% or less Ti could be forged. The Cu-rich portion of the diagram was investigated by thermal and X-ray methods. A eutectic between the solid solution and Ti or a compound is located between 20 and 27% Ti. X-ray examination showed that the Cu lattice expanded with the addition of Ti. The solubility limits of Ti in Cu vary from 0.4% at room temperature to about 4 or 4.5% at the eutectic temperature. Alloys in this range are age-hardenable. The tensile strength of a quenched 2.58% Ti alloy increased from 54,000 to 104,000 lb./in.^{2} on aging 8 hr. at 400° C. Its elongation in 2 in. fell from 37.7 to 16.7%. The electric resistance decreases on aging. Contains 3 references. JLG(2)

Conductivity of Aluminum Silicon Alloys. (Leitfähigkeit von Aluminium-Siliciumlegierungen.) W. Fraenkel & R. Hahn. *Metallwirtschaft*, Vol. 10, Aug. 14, 1931, pages 643–644.

The range of alloys examined contained from 0 to 15% Si and were prepared partly with American 99.95% pure Al, partly with technical 99.7% Al. Conductivity was determined in the quenched at 500° and aged at 300° condition. Conductivity is higher in the aged condition. The angle in the curve of the quenched alloys points to the solid solubility of about 1.5% Si in Al at 550°. In samples made with pure Al, the Si appears to separate faster than when traces of Fe are present. Si practically does not conduct current at all. CEM(2)

Studies of Commercial Cast Alloys. (Untersuchungen an technischen Gusslegierungen.) O. Bauer & O. Vogel. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 51–83, 85 figs.

Test castings of a cast 90 : 10 phosphor bronze, of cast brass 2 : 1 brass, of silumin and elektron were made according to commercial practice, in 5 cross sections ranging from 1 to 10 cm. The bars were upright cylinders cast on a common base block by bottom pouring; one lot of elektron was also cast horizontally in keel-block bars. Each material was cast by 2 firms so that check observations were made in each series. These were subjected to very extensive studies for chemical segregation, structure, hardness, density and porosity along the length and cross-section. The results show wide variation in porosity which was greater where freezing was slower. The keel-block elektron castings were sound. On the largest bronze casting the Brinell varied as widely as from 57 to 91, the brass from 43 to 55, the silumin from 42 to 50 and the elektron from 54 to 63. Marked differences in density were found in all and chemical segregation was notable in the bronze and brass. The authors conclude that to give a real picture of the true properties of a casting, extremely extensive examination is required, that different alloys demand different methods of casting and that in practice, far too little attention is paid to these matters. As an object lesson to show that one test on a cast specimen may be far from showing its true properties, the article is a very telling one. HWG(2)

Cadmium in High Lead Bearing Metals. (Ueber das Kadmium in Hochbleilagermetallen.) K. L. Ackermann. *Metallwirtschaft*, Vol. 10, July 24, 1931, pages 593–597.

Contains 9 references. This investigation was undertaken to determine whether cadmium additions to lead base bearing metals would be of any value. The alloys examined included Pb-Sb-Cd, Pb-Sb-Sn-Cd, Sb-Cu-Cd, Pb-Sb-Sn-Cu-Cd and Pb-Sb-Sn-Ni-Cd. Hardness, elastic limit, impact, compression and frictional tests were made. 22 photomicrographs show the structures obtained and several constitutional diagrams are given. Only alloys with more than 5% Sb and less than 4% Cd can be considered. With less Sb they are too soft and with more Cd too brittle. When Cd is substituted entirely for Sn the alloys become softer; when it is partly substituted they become harder. All Pb-Sb-Cd and Pb-Sb-Sn-Cd alloys have lower elastic limits and impact strength than the corresponding alloys without Cd. While Cd is closely related to Sn chemically, it forms long needles of CdSb in Pb base bearing metals. Cu and Ni, when present, form Cu_2Sb and Ni_2Sb_3 and do not form compounds with Cd. The hardness of Pb base alloys containing Cu or Ni is raised slightly by additions of Cd over .6%, but lowered considerably when Cd is partly or completely substituted for Sn. The elastic limit and impact strength are lowered by Cd additions. Friction is also increased by Cd additions. The conclusion is that Cd additions are not beneficial. CEM(2)

Some Properties of Silicon—"Aluminium—Bronzes." L. J. Brice. *Journal Institute of Metals*, Vol. 45, No. 1, 1931, pages 209–228 (includes discussion); *Engineering*, Vol. 131, Mar. 27, 1931, page 410.

Paper read before the Institute of Metals, Mar. 12, 1931. See *Metals & Alloys*, Vol. 2, May 1931, page 94. LFM(2)

Thermionic Emission of Oxide-Coated Cathodes Containing a Nickel-Barium Alloy Core. N. C. Beese. *Physical Review*, Vol. 36, Series 2, 1930, pages 1309–1313.

The thermionic emission from filaments coated with Ba and Sr oxides is appreciably increased by using an alloy of Ni with 0.15% Ba as the base metal instead of pure Ni. The effect is particularly marked with thin coatings of oxide. On prolonged heat treatment at a high temperature (1300° C.), the Ba evaporates and the increased activity is lost which shows that the effect is due to the nature of the metal core. Ha(2)

Experiments to Increase the Electric Conductivity of Hard Conductor Aluminum by Thermal Treatment. (Versuche zur Erhöhung der elektrischen Leitfähigkeit von hartem Leitaluminium durch thermische Behandlung.) H. Bohner. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July–Aug. 1931, pages 276–279.

The electrical conductivity of hard material, beside depending on the chemical composition of the Al, depends on the rolling temperature and can be increased considerably, independent of composition, by an intermediate annealing of the rolled wires at about 300° C. The tests and results are given in detail. 7 references. Ha(2)

Pewter and Its Manufacture. B. Egeberg. *Brass World*, Vol. 27, Aug. 1931, pages 177–179.

A description of the alloys, melting, rolling practice and peculiarities in heat treatment of pewter, reprinted from the "Monthly Review" of the American Electroplaters' Society. Variation in hardness at various temperatures is shown by a curve. Pewter is softened by cold work, but tests prove it is not weaker than the annealed metal. WHB(2)

The Alloys of Lanthanum. (Le leghe del lantanio.) G. Canneri. *La Metallurgia Italiana*, Vol. 23, Sept. 1931, pages 803–823, 34 illustrations.

Electrolytic lanthanum of m. p. 812° C., density at 20°, 6.153 was prepared by electrolysis of fused lanthanum and sodium chlorides. The purity of the lanthanum is given as 99.6%. The method of purification of the lanthum chloride is not discussed, nor is proof given of the absence of other rare earth metals though it is stated that the 0.4% of impurities consists of Si, Al, Mg and C. Cooling curves of alloys of La with Pb, Sn, Tl, Mg, Ag, Cu and Au were taken and tentative equilibrium diagrams constructed. Attempts to prepare alloys of La with Zn or Cd were not successful. With Pb, Sn, Tl and Au, very high melting compounds are formed, e. g., $PbLa_2$, m. p. 1318° C. and La_2Sn, m. p. 1425° C. The following compounds were indicated: Pb_2La, PbLa, $PbLa_2$; La_2Sn, La_3Sn_3, $LaSn_3$; Tl_3La, TlLa, $TlLa_2$; La_4Mg, LaMg, $LaMg_3$, $LaMg_4$; LaCu, $LaCu_2$, $LaCu_3$, $LaCu_4$; $LaAg_2$, $LaAg_3$, LaAg; $LaAu_3$, $LaAu_2$, LaAu, La_2Au. A few qualitative comments are made on the properties of the various alloys and micrographs of some are shown. HWG(2)

PROPERTIES OF FERROUS ALLOYS (3)

A Study of Some Properties of Structural Silicon Steels. (Étude de quelques proprietes des aciers de construction au silicium.) Tamura. *Revue de Métallurgie*, Vol. 28, July 1931, pages 405–416.

Three steels of low carbon silicon type (0.08% C, 0.33% Mn, 0.33–1.96% Si) and one structural silicon steel (0.13% C, 0.96% Mn, 0.96% Si) were studied. A_1 point rises slightly with increasing Si content; A_3 somewhat faster but with 1.96% Si the latter was not found up to the temperature of 1100°. The structure of normalized silicon steels is the same as of common steel but the grain size grows with the Si content. The resistance grows with Si at the rate of 12.1 microhms/cm.^{2}/cm./1% of Si. The permeability increases with Si with low inductions (B up to 14,500) and decreases afterward. The elastic limit and tensile strengths are increased for 1% Si by 3.5 and 7.3 kgs./mm.^{2} respectively but the elongation drops. Resilience, as well as corrosion resistance, diminishes rapidly as Si increases. Hardness increases after heat treatment directly proportionally to Si content. Structural steel of Si type has higher physicals than carbon steel of the same C content but it rusts much faster. The effect of aging is very weak in its case. JDG(3)

Low-carbon Steel. H. B. Pulsifer. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 426, Sept. 1931, 31 pages.

Frequency curves that show the irregular properties of unheat-treated bolts are given. A 0.10% C steel was quenched from various temperatures. A martensitic structure was formed on quenching from high temperatures (1800° F.). Irregular properties were found in commercially quenched cap screws, that were heated to about 1600° F. and dumped in water. Micrographs show the structures produced by various treatments. The properties of carburized steels are discussed. 18 references. JLG(3)

Alloy Cast Steel. (Legierter Stahlguss.) E. Kothny. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 31, 1931, pages 613–618; Aug. 7, 1931, pages 635–639.

A detailed discussion and analysis of properties and the application of Mn steel, Ni steel, Cr steel, Mo steel, Cr-W steel (especially for seamless pipes, with 0.7% C, 1.0% Cr and 2% W), Si steel, Cu alloyed steel. For details, the paper and the 27 references must be referred to. Ha(3)

The Combined Influence of Cold-Work and Finely Dispersed Precipitations upon Properties of a Metal. (Die Beeinflussung des Eigenschaftswertes eines Metalles durch Zusammenwirken von Kaltreckung und fein verteilten Ausscheidungen). W. Köster. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, pages 176–177.

The lecture delivered before the Deutsche Gesellschaft für Metallkunde, 1930, directs the attention to the changes of the coercive value of Fe-N-alloys due to cold work and to N segregations. The independence from the succession of the mechanical and heat treatment could be established and the decrease of the specific influence of the precipitation with rising amounts of deformations could be proved. EF(3)

The Machinability of Gray Iron as Dependent on the Content of Silicon. (Die Schneidfähigkeit von Grauguss in Abhängigkeit vom Silizium- und Kohlenstoffgehalt.) E. Diepschlag & Fr. Eggert. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 17, 1931, pages 313–318.

Investigation has proved that the common opinion that an increase of Si always gives an improvement in the workability is wrong. The contrary is true if the C does not amount to more than 4%. The C content largely determines the machinability; the higher it is, the lower are the cutting temperatures. An increase of Si seems to act favorably on the machinability only above 4% C. It is, therefore, disadvantageous to use high Si iron for normal castings which must later be machined by chipping tools if the C content does not amount to at least 4%. The high Si content only makes the castings more expensive without improving the machinability, and at less than 3.5% C the cutting temperatures are even noticeably increased. Test results are given in detail. Ha(3)

Effect of Degree of Rolling, Finishing Temperature and Heat Treatment upon the Mechanical Properties, the Sensibility toward Aging and the Structure of Plates. (Einfluss des Walzgrades, der Walzendtemperatur und der Wärmebehandlung auf die mechanischen Eigenschaften, die Alterungsempfindlichkeit und das Gefüge von Grobblechen.) F. Körber & K. Wallmann. *Stahl und Eisen*, Vol. 51, Apr. 16, 1931, pages 491–497.

The article is an abstract of the original publication in *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 13, 1930, pages 171–191. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 161. GN(3)

Comparative Investigation on Natural and Artificial (Aston) Wrought Iron. (Vergleichende Untersuchungen an natürlichem und künstlichem Schweisstahl (Aston-Eisen.) W. von Gutmann & H. Esser. *Stahl und Eisen*, Vol. 51, Sept. 24, 1931, pages 1193–1197.

After giving a general description of the Aston process, the authors report the results of comparative investigations on the structure and properties of wrought iron made by the old puddling process and the new Aston process. The chemical composition of both the wrought irons does not differ to a large extent. The C content of Aston wrought iron is always somewhat lower and the S content somewhat higher than that of puddled iron. The structures show no remarkable differences. Tests on red shortness and weldability give practically the same results. In segregation hardening, Aston wrought iron is inferior to puddled wrought iron which is undoubtedly due to the various C contents. The notch toughness of Aston iron is always somewhat higher than that of puddled iron. The tensile strength of Aston iron is somewhat lower and the elongation somewhat higher than those of puddled iron. Strain hardening tests indicate no differences between Aston iron, puddled iron, Armco iron and Krupp soft iron. Aston iron has a lower aging sensibility than puddled iron, Armco iron and Krupp iron. In corrosion tests, Aston iron shows some inferiority in comparison with the other irons mentioned. Aston iron satisfies all requirements which a good wrought iron must meet. But for unimportant details, puddled wrought iron and Aston wrought iron are completely alike. GN(3)

Austenitic Stainless Steel 18-8. (L'acier austénitique inoxydable; Cr 18-20, Ni 8-10.) J. Galibourg. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 173–179. 35 references.

General discussion of properties and uses. HWG(3)

Comparison of Annealed Nickel, Nickel Chromium and Carbon Steels. (Caractéristiques mécaniques des aciers au nickel, et au nickel chrome recuits, comparaison avec les aciers ordinaires.) J. Galibourg. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 157–171. 9 figures, 21 tables.

Tabulation of data from many sources, and its collection into curves. Composition is given in the tables, the curves are plotted on the basis of equal tensile strength. The relations between tensile strength and elastic limit, elongation and impact are shown for carbon steels as a base line for comparison. Ni raises the elastic limit and impact, elongation being of the same order as for carbon steels. Compared to the carbon steels, the Ni-Cr steels show a marked increase in elastic limit and some superiority in elongation the higher the tensile strength, while the minimum impact values are above the maximum values for carbon steels of the same tensile strength. HWG(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Acid Resisting Metals: A Few Comparative Tests. J. W. McMyn & V. Edge. *Chemistry & Industry*, Vol. 50, June 5, 1931, page 474.

Corrosion rates, as determined in test tubes, are given for "Staybrite" steel, "Monel" metal, "Batterium" metal, and copper in acetic acid, sulphuric acid, hydrochloric acid, sodium chloride, sodium carbonate, sodium hydrate, sodium hypochlorite and sodium sulphide solutions. PRK(4)

The Physical Chemistry of Corrosion Phenomena. (La chimica fisica dei ferromeni di corrosione.) F. Giordani. *Giornale di chimica industriale ed applicata*, Vol. 13, June 1931, pages 275–281.

A general résumé of the principles of corrosion, discussing passivity, the protective action of Cr in stainless steels, the analogy between the electrochemical behavior and the thermoionic phenomena of metals, inhibitors, differential aeration and especially the action of protective metallic coatings. It is pointed out that beside the position in the electromotive series, the hydrogen overvoltage of a metal under the conditions in which it is subjected to corrosion, has to be considered. A curve from the work of T. Maresca is given to show that the potential of Sn is less noble than that of Fe in fully acid or fully alkaline solutions, but that between about pH_2 and pH_{12} the positions are reversed. HWG(4)

Soil-Corrosion Studies, 1930. Rates of Corrosion and Pitting of Bare Ferrous Specimens. K. H. Logan & V. A. Grodsky. *Bureau of Standards Journal of Research*, Vol. 7, July 1931, pages 1–35.

Data on loss of weight and pitting of specimens of Bessemer steel, open-hearth steel, pure open-hearth iron, copper-bearing steel, wrought iron, sand-cast iron and DeLavaud cast iron, buried 8 years in 47 soils are given, and, for comparison, data obtained in each previous 2 year period. In general, the rate of attack decreases with time. Vast differences are shown in the corrosiveness of the different soils. Shorter and less extensive tests were made on malleable, on high tensile cast iron, on cast steel, and on high silicon cast iron (corrosion resistant type), and on 27% Cr, 0.2% steel. The last two materials were but slightly attacked. Of all the others, it is said: "the data so far obtained do not indicate that any one of the commonly used pipe materials is markedly superior to the others for general use underground." "If a soil is corrosive with respect to one ferrous material, it is corrosive with respect to the others also." "Other things being equal, the thicker the specimen, the lower will be its rate of deterioration if the test is continued until the puncture of the specimen occurs. This observation has a very practical application to the selection of the wall thickness of pipes which are exposed without protection to corrosive soils." HWG(4)

Resistance of Chromium Steel against Alkali Solutions. (Ueber die Widerstandsfähigkeit des Chromstahls gegen Alkalilösungen.) Albert Krüger. *Chemiker Zeitung*, Vol. 55, May 1931, page 335.

Preliminary tests indicate the suitability of vessels, crucibles, etc., made of Cr steel as a substitute for Pt vessels for the analytic determination of Fe, Al, Ni, if they are precipitated as hydroxides. Glass or porcelain vessels introduce serious errors under these conditions. Cr steel is also resistant against H_2O_2 and Na_2S in alkaline solutions. (4)

Use of Chemical Equipment Minimizes Corrosion in Textile Mills. Percy C. Kingsbury. *Textile World*, Vol. 80, Sept. 12, 1931, pages 26–27.

Stoneware containers and rolls and acid-resistant equipment for handling of corrosive materials used in bleaching and dyeing and finishing of textiles are described. Ha(4)

The Atrament-Process. (Das Atramentverfahren.) A. Karsten. *Oberflächentechnik*, Vol. 8, Sept. 15, 1931, pages 199–200.

The new process aims to provide a perfect protection against corrosion without, at the same time, changing the dimensions of the objects to be protected or their physical properties. It consists of a chemical change of the surface iron and steel parts by phosphoric salts of determined composition. The surface assumes, thereby, a pleasing, ebony black appearance. By further treatment, other colors can be obtained. It resists attacks of water, atmospheric and other influences. The parts must be free from grease, rust and oxides before being treated with atramentol. A short description of the bath and treatment of coloring is given. Atramentol is made by the I. G. Farbenindustrie A.-G., Frankfurt a.M. Ha(4)

Wool-Fat as Rust Protection. (Wollfett als Rostschutzmittel.) Freitag. *Oberflächentechnik*, Vol. 8, July 21, 1931, page 155.

Wool fat dissolved in tri-chloraethylen is recommended as a convenient and easily removable coating for temporary purposes such as rust protection during storage, etc. Ha(4)

Corrosion Reduction with Lime Treatment. Edw. S. Hopkins. *Water Works & Sewerage*, Vol. 78, July 1931, pages 191–192.

The corrosive effect of the soft water for the water supply of Baltimore, Md., was eliminated by the addition of lime which entirely absorbed the CO_2. The addition is automatically controlled by a Leeds and Northrup recording potentiometer. The cost of lime application amounted to 16c per million gals. of water pumped in 1930. The water leaving the plant contains only 0.03–0.10 parts per million of Fe. Ha(4)

Alloys Resistant to Heat and Sulphur. (Ueber hitze-und schwefelbeständige Legierungen.) H. Gruber. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 151–157.

The author places emphasis on the influence of the melting points of the various sulphides formed at the surface upon the sulphur stability. Furthermore the nature of the surface layer upon the progress of the attack was investigated. In addition to the rise of the melting points of the sulphides at the surface of Al, the formation of a gas tight oxide film is assumed. Besides melting point and density to gases, the importance of the thermal expansion is discussed. Experiments were carried out in an H_2S-atmosphere at 700°, 800°, 900° and 1000° C. and some 29 various alloys were employed. The analyses are given and refer to Fe-Ni-Cr alloys with additions of Mn, Al, Co, Mo and W. The tests resulted in the adoption of the following heat- and sulphur-resistant alloy which turned out best: 20% Fe, 61% Ni, 15% Cr, 4% Mn, 10% Al. EF(4)

Corrosion of Metal Hydroplanes. (Korrosion bei Metallwasserflugzeugen.) Guido Guidi. *Metallwirtschaft*, Vol. 10, Aug. 14, 1931, pages 645–646.

One reference. The most important effect of seawater on metals is of electro-chemical character, especially when in contact with 2 or more different metals. Immersion and spray tests are discussed. They can be evaluated by determining the loss in weight or loss in strength. Investigation of the potential difference between pairs of metals in electrolytes under various conditions show that there is a direct relation between the tendency to corrode and the electric currents. Agitation of the electrolyte increases the potential difference up to a certain point, beyond which no increase in potential difference or corrosion takes place. Protective measures include mechanical means, painting exposed parts, and electrochemical, by interposing a metallic layer. Alclad, Duralplat, stainless steels and Cd plating have been investigated by the potential difference method. CEM(4)

ILLIUM is not a "new" alloy. It has been in successful use more than 15 years, sometimes in acids—sulphuric, nitric, acetic, phosphoric, *mixed* nitric and sulphuric, etc.—sometimes in alkalies.

While not a cure-all for every ill, ILLIUM *is* a complete, permanent and moderate priced answer to many of the corrosion troubles commonly encountered.

Dense, close grained, with considerable tensile strength, ILLIUM withstands heat, torque, impact and wear. It is especially recommended for pump and valve parts, agitators, or pieces requiring accurate machining.

UNIVERSAL
CORROSION-RESISTANT
ALLOY
sold in form of castings, easily machined, takes high polish

ILLIUM castings, rough or finished are made to your specifications in our modern foundry. Our engineers will quote from your patterns or drawings, or will work with you in designing ILLIUM parts for your product.

Weather-OMeter

Tests Metals

The aging and deterioration of metals and various alloys under the action of the elements and the various reagents they encounter in processes of manufacture and industrial use, forms one of several problems confronting the metallurgical laboratory today.

In the making of accelerated, controlled, measureable studies of this kind the Weather-Ometer has rendered unique service. It gives sunlight—rain—cold—heat—humidity—reactions that faithfully reproduce those of nature only greatly speeded up. Interpreted in Weather-Ometer Hours, the findings are understood and accepted the world over.

Weather-Ometer tests metals for weathering or corrosion action. Some of the applications of this nature have been assembled in a new bulletin that the metallurgist will find a distinct addition to his laboratory library. Ask for Bulletin MA-12.

The Corrosion Protection of Metal Oxide Coatings. (Korrosionsschutz von Metallen-Oxydische Ueberzuege.) E. LIEBREICH. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Aug. 29, 1931, pages 1110–1111.

This is a review of the modern methods of producing oxide coatings of metals by chemical treatment. This method provides a much better protection against corrosion (if their structure is good) in spite of the minute thickness of the oxide films than the protection by thicker coatings which are not so elastic and can, therefore, not follow expansions so easily and are more liable to cracking. These thin films are now often alloyed with other metals such as Ni, Cr, Mn, etc.; this increases the protective action. Several methods used for producing these films are described. Ha(4)

Corrosion of Tin Plate on the Inside of Preserving Tins. (La corrosion du Fer-Blanc a l'Intérieur des Boites de Conserves.) ED. LASAUSSE. *Chimie et Industrie*, Vol. 25, June 1931, pages 1348–1353.

Previous papers relating to the quantity of metal found in preserved products do not indicate the conditions under which the products were prepared, but only the length of time in which corrosion has occurred. Among the acids usually present in cans and capable of causing corrosion, the most active is acetic acid; it causes almost all the bulging found when the cans are opened. Fatty acids and citric acid attack the metal to the same degree, but only produce incomplete bulging. American authors note that tertiary amino acids can facilitate the dissolving of Sn. Conversely, we note that the introduction of sodium phosphate in the liquids in the tins definitely retards the corrosion. We think that a thin film of insoluble phosphate is formed which causes the retardation. MAB(4)

Soil-Corrosion Studies: Nonferrous Metals and Alloys, Metallic Coatings and Specially Prepared Ferrous Pipes Removed in 1930. K. H. LOGAN. *Bureau of Standards Journal of Research*, Vol. 7, Sept. 1931, pages 585–605; *Bureau of Standards Research Paper* No. 359.

The information concerning soils which has been obtained as the result of the bureau's soil-corrosion investigations makes it clear that the rate of corrosion of any metal exposed to soil can not be accurately expressed by a single figure or group of figures. On account of the variations found in all soils the influence of the character of the soil, differences in contact between the soil and the metal, changes in the supply of oxygen and moisture, and the effects of the corrosion products, the best that can be hoped for is an expression representing the average rate of loss of weight or pitting accompanied by a figure for the standard deviation, probable error, or some other expression indicating how much the behavior of any single specimen may be expected to differ from the behavior of the average of a representative group of specimens. Average values sufficiently accurate to show small differences in the performance of competing materials can only be secured through the testing of a very large number of specimens. Since in any one case any material may prove considerably better or worse than the average, it is doubtful whether the drawing of fine distinctions between materials would be of practical value except for the consumers of very large quantities of materials. Attention should, therefore, be directed chiefly to the unmistakable differences between different kinds of materials rather than to possible small differences between nearly similar materials. The most general conclusion to be drawn from the data is that for best results the material must be chosen to fit the soil in which it is to serve, since no one material is best for all soil conditions. Another general conclusion is that small differences in the data should not be considered significant, since it is improbable that a repetition of the test would yield identical results. In nearly all soils Cu and alloys high in Cu resist corrosion well. Muntz metal shows at least slight dezincification after 6 years burial in half of the soils investigated and serious dezincification in a few of them. In nearly all of the soils considered, Pb corroded much less rapidly than Fe or steel. The rates of pitting of commercial lead specimens were 3 mils/year or greater in 25% of the soils. The Pb containing Sb showed rates of pitting greater than 3 mils/year in nearly 50% of the test locations.

The outer metallic ribbon of the parkway cable showed corrosion in most test locations. The inner ribbon was somewhat less corroded. Serious pitting of the Pb sheath occurred only in the soil containing alkali carbonates. All of the metallic coatings tested appeared to increase the life of the material to which they were applied. Comparison of the effectiveness of the metallic coatings is difficult because they differed in thickness. All coatings showed evidences of deterioration in several soils. In most of the soils, there was no evidence that the rate of penetration by pitting increased after the lead coating had been punctured. The possibility is suggested that the relative positions of lead and iron in the electrochemical series depends upon the soil in which specimens composed of lead and iron are placed. The precision of the data is insufficient to show at this time whether one base material is better than another for galvanized sheets to be used underground, but it appears that any difference which may exist is not great. The Corrosion of Early Chinese Bronzes. WILLIAM F. COLLINS. *Journal of the Institute of Metals*, Vol. 45, No. 1, 1931, pages 23–55 (with discussion) abstracted in *Engineer*, Vol. 131, Mar. 20, 1931, page 327; *Engineering*, Vol. 131, Mar. 13, 1931, page 366.

Paper read before the Institute of Metals, Mar. 11, 1931. See *Metals & Alloys*, Vol. 2, May 1931, page 97. LFM(4)

The Resistance of Wrought-Iron Vessels to Fluorosulphonic Acid. (Ueber die Widerstandsfähigkeit von schmiede-eisernen Gefässen gegen Fluorsulfonsäure.) HANS J. BRAUN. *Metallbörse*, Vol. 20, Sept. 24, 1930, page 2134.

From the results obtained on testing the resistance of a wrought-iron retort to $HFSO_3$ at ordinary temperature, at 130° and at 150° C. it is concluded that wrought-iron vessels are sufficiently resistant to this acid. The method of testing is described. WHB(4)

Corrosion of Iron and Steel in Ship Structures. J. W. DONALDSON. *Iron & Steel Industry & British Foundryman*, Vol. 4, June 1931, pages 313–316.

Causes of corrosion and methods for corrosion prevention of ship structures are discussed. The author summarizes data from other investigations on the relative corrodibilities of various commercial forms of iron and steel in sea water. CHL(4)

The Ways in Which Rust Forms. (Les Modes de Formation de la Rouille.) GEORGES CHAUDRON. *Chimie et Industrie*, Vol. 26, Apr. 1931, pages 273–279.

The conclusions which are made follow: all the ways for decreasing or stopping the rate at which flakes are formed can be utilized for protecting metals; progress has been made in electrochemistry, and research may be expected to follow this trend; important discoveries will be made in the laboratories where science has the best of knowledge and apparatus. Various methods for the protection of rust are discussed: the electrochemical theory of corrosion; the phenomena of Evans; corrosion tests made under pressure of oxygen; the function of a flake: aerated and non-aerated iron; corrosion by seawater; protection by plugs, by cathodic polarization, by polarization of anode surfaces; the corrosion of iron by rust; the application of protective paints and their choice. MAB(4)

Classification of Corrosion-Resisting Steels. H. N. BOOKER. *Paper Industry*, Vol. 12, Aug. 1930, pages 849–851.

The corrosion-resisting steels at present on the market are grouped into 4 classes, and a few of the properties of each group are given. WHB(4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

The Structure of Copper-Zinc Alloys. (Sur la structure des alliages cuivre zinc.) W. Broniewski & J. Strasburger. *Revue de Métallurgie*, Vol. 28, Jan. 1931, pages 19–29; Feb. 1931, pages 79–84. 41 references.

Published data do not definitely establish the composition of the particular compounds of Cu–Zn system. To obtain the necessary equilibrium specimens cast in chills and containing less than 49% Zn were annealed at 400° for 1000 hours, and those with higher content of Zn for 3000 hours. The treatment was conducted in an electric furnace well luted with fire clay so that the changes in the composition were found only in a very thin outside layer of specimens. Parallel series of tests were made on cast and annealed specimens. Electrical conductivity, thermoelectric power, electromotive force of the solution, dilatation and Brinell hardness were determined. These tests and microscopic evidence placed the limits of solid solubility of α-phase between 0 and 35 atomic %, of β 46 to about 49%, of γ 59 and 67%. After 3000 hours annealing ϵ-phase was never perfectly homogeneous which interfered with the determinations of its limits of solid solubility which tentatively can be given as 79 and 87%. The range for η-phase is within 98 and 100% Zn. The existence of CuZn, $CuZn_2$ and $CuZn_8$ at room temperatures was reasonably well established. The shifting of the maxima of corresponding curves from theoretical 50% to about 49.6% can be explained on the assumption of the partial decomposition of CuZn into γ-and α-phases. JDG(5a)

MultiComponent Systems Involving Iron. III. The System Iron–Phosphorus–Silicon. (Ueber Mehrstoffsysteme mit Eisen. III. Das System Eisen–Phosphor–Silizium.) W. Hummitzsch & F. Sauerwald. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 194, Dec. 9, 1930, pages 113–138.

The system, containing an excess of Fe was examined chemically, thermally and metallographically. Fe_3P–FeSi is quasi-binary. Fe–Fe_2Si–FeSi is an independent, 3-component system. Fe_3P–FeSi is not quasi-binary. A ternary eutectic at 1018° consisted of 6.35% Si; 7.45% P; 86.20%Fe. At 1110° there is an equilibrium of the form: Liquidus k + Fe_3P = Fe_2P + FeSi. The liquidus is 13.55% Si; 6.00% P; 80.45% Fe. Eleven diagrams are given and discussed; also a number of photomicrographs. (5a)

The Mode of Deformation of a Single Crystal of Silver. H. J. Gough & H. L. Cox. *Journal Institute of Metals*, 45, No. 1, 1931, pages 71–97 (with discussion); abstracted in *Engineer*, Vol. 151, Mar. 20, 1931, page 328; *Engineering*, Vol. 131, Mar. 13, 1931, pages 366–367.

Original paper read before the Institute of Metals, Mar. 11, 1931. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 142. LFM(5a)

A Note on the Silver-Rich Aluminium-Silver Alloys above 600° C. T. P. Hoar & R. K. Rowntree. *Journal Institute of Metals*, Vol. 45, No. 1, 1931, pages 119–125; abstracted in *Engineering*, Vol. 131, Mar. 20, 1931, page 382.

Includes discussion. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 142. LFM(5a)

Constitution of Aluminum-Iron-Silicon Alloys. (Konstitution der Al-Fe-Si Legierungen.) V. Fuss. *Metallbörse*, Vol. 20, Dec. 13, 1930, page 2734.

Fuss' results are not in accord with those of Fink and Van Horn or those of Dix and Heath. He found only one intermetallic compound at the Al end of the diagram. This compound contained approximately 23% Si and 77% $FeAl_3$. This corresponds to $Al_3Fe_2Si_3$ and is probably identical to Dix and Heath's β Fe-Si. Fuss found a peritectic between the $FeAl_3$. Microscopic examination was employed. No other method of examination was mentioned in the abstract. WHB(5a)

The Macro-Etching of Aluminium-Silicon Alloys. William Hume-Rothery. *Institute of Metals, Advance Copy* No. 572, Sept. 1931, 4 pages.

The macrostructures can be brought out by etching in an aqueous solution containing 150 to 160 grams of $CuCl_2$ per liter. The specimen is held in the solution until a vigorous reaction occurs, removed, the deposited Cu brushed off, and this procedure repeated until the desired effect is produced. A final brightening may be produced by immersion in a solution of CrO_3. 1 reference. JLG(5a)

Transformations in the Copper-Gold Alloys. John L. Haughton & Ronald J. M. Payne. With an Appendix on X-ray Examination of Gold-Copper Alloys. G. D. Preston. *Institute of Metals, Advance Copy* No. 571, Sept. 1931, 24 pages.

Alloys from 20 to 70 atomic % Au were studied by determining the electric resistance of the slowly cooled alloys at room temperature, by determining the change in resistance with change in temperature and by microscopic examination. The existence of transformations in alloys corresponding to the formuae AuCu and $AuCu_3$ were confirmed, and a third transformation corresponding to a third compound, Au_2Cu_3, was detected. An equilibrium diagram is drawn to show the transformations by which the supposed compounds are formed. The crystal structures of some of the alloys were studied by X-ray methods. The quenched 51.2 atomic % Au alloy had a face-centered cubic lattice (3.94 A. U.), and gave no indication of a regular arrangement, as to kind, at the points of the lattice. This alloy when slowly cooled had a body-centered tetragonal lattice (a = 2.79 A. U., c/a = 1.31) with the Au and Cu atoms arranged regularly at points of the lattice. The transformation temperatures were dependent on the O content of the alloys, and it was found necessary to melt in a vacuum. An appendix describes the method and fixtures used in determining the electric resistance throughout a temperature range. Contains 7 references. JLG(5a)

The System Iron–Carbon–Vanadium. (Beitrag zur Kenntnis des Systems Eisen–Kohlenstoff–Vanadin.) Hans Hougardy. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1930, pages 497–503; *Stahl und Eisen*, Vol. 52, May 7, 1931, pages 592–593; *Mitteilungen aus dem Forschungs-Institut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 2, No. 3, 1931, pages 39–60.

The effect of V upon the physical properties of Fe-C alloys was studied with steels containing C: 0.10%, 0.30%, 0.70%, 1%, 1.50%, 2%, 2.50% and 3%; V: 0.40%, 0.80%, 1.50%, 2.50%, 4%, 5.60%, 8%, 12% and 16% The ability of V to suppress the γ-phase of pure Fe is not abolished by C but only shifted to higher contents of V. F. Wever and W. Jellinghaus found that the γ-field is closed at 1.1% V. In the presence of C, the percentage of V at which the γ-field is closed is governed by the relation $V = \frac{C}{0.175} + 1.1$, where C is the carbon content. With lower V contents only V_4C_3 is formed and no Fe_3C is present. Only excessive amounts of V form solid solutions with Fe. V_4C_3 and Fe_3C form no double carbides; however, at higher temperatures limited amounts of V_4C_3 are dissolved in γ-Fe. The particulars of the results on hardness, hardenability, deep hardening, appearance of fracture, critical points, structure of the steels tested are due to the above behavior of V and V_4C_3, respectively. The hardenability (hardness vs. quenching temperature) is retarded above certain contents of V (relative to the content of C) and finally the hardness does not increase at all with the quenching temperature. The A_1 point is in the average increased by 10° independent of the amount of V. The lower boundary lines of the γ-field are shifted to higher carbon contents without essentially affecting the size of the γ-field. New structures were not observed in the steels investigated. The 3-dimensional diagram Fe-C-V was established up to 3.4% C and 5.6% V. GN+GTM(5a)

LEITZ-OGRAPH

Your Metal Samples as a guarantee for unfailing and reliable results

LEITZ MICRO-METALLOGRAPH "MM"
(Inverted Microscope with Camera)

Preparing the metal sample in a faultless manner is the first step toward a perfect micro-analysis

The "Guthrie-Leitz" Automatic Polishing Machines, of ONE-, TWO-, and FOUR-Spindle Type, by means of a magnetic holding and oscillation device, produce these results in an automatic manner, eliminating all elements of human equation. These Automatic Polishing Machines represent a distinct labor saving device, thereby repaying their cost in a short time. **Another outstanding feature of these Polishing Machines is that the specimen can readily be removed during operation.**

As the next step toward an unfailing micro-analysis, the microscope equipment should be perfect mechanically as well as optically.

The Leitz Micro-Metallograph "MM" possesses all the required qualifications to render a microscopic image of unequalled brilliancy, definition and flatness of field.

On the Equilibrium Diagram of the Copper-Silicon System. K. Iokibe. *Kinzoku no Kenkyu*, Japan, Aug. 1931, pages 433–456.

The equilibrium diagram of the Cu-Si system was investigated by means of total and differential thermal and dilatometric analyses, electric resistance measurement and microscopic examination. The diagram, obtained by the author, showed the following: (1) A homogeneous phase "X" having the composition of 89.4–89.3% of Cu and 10.6–10.7% of Si is formed at 800° C. by the peritectoid reaction $\delta + \epsilon \rightleftarrows X$. The reaction is very slow and was found only in annealed specimens. The electric resistance of "X" phase is very small compared with that of γ and ϵ'' phases. (2) The δ—γ transformation which had been thought to exist in the heterogeneous range lying between α and ϵ, is now proved to appear, in the equilibrium condition, only in the alloys containing less Si than that of "X". Similarly, the ϵ—ϵ' transformation appears only in the alloys whose Si content exceeds that of "X." (3) Besides the known transformation ϵ—ϵ' (626–556° C.), the ϵ phase shows another one ϵ''—ϵ', the transition interval lying between 558° and 442° C. KT(5a)

The Affinity of Metals for Sulphur. I. The Thermal Equilibrium between Hydrogen and the Sulphides of Iron, Tin, Cadmium, Bismuth and Antimony. (Die Affinität von Metallen zu Schwefel. I. Mitteilung. Das thermische Gleichgewicht zwischen Wasserstoff und den Sulfiden von Eisen, Zinn, Cadmium, Wismut und Antimon.) E. V. Britzke & A. F. Kapustinsky. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 194, No. 4, 1930, pages 323–350.

The thermal equilibria between H and the sulphides of Fe, Sn-Sb, Bi and Cd were investigated in the temperature range from 400° to 1000° C. The results are tabulated and the dissociation-tensions, heat of formation of sulphides and the affinities to the metals in question are determined Ha(5a)

On the Inverse Segregation in Simple Eutectic Alloys and Its Mechanism. K. Iokibe. *Kinzoku no Kenkyu*, Japan, July 1931, pages 372–397.

The inverse segregation was observed in Zn-Sn alloys which form a simple eutectic. The density of the inner portion of the castings is smaller than that of the outer portion. The chemical analysis showed that the former contains more Zn and hence is lighter than the latter. This fact was also confirmed by microscopic observation. The inverse segregation was found to be more conspicuous when the solidification interval was great. The dissolved gas had no effect upon the inverse segregation. Many minute cavities were found in the center of the ingot, this causing the low density. The contraction of casting was greatest at the center. From these facts the author concluded as follows: By the solidification shrinkage of primary crystals shrinkage cavities are formed at the outer portion of the ingot and cause the outward movement of the mother liquid from the inner portion. Thus, more Sn is contained at the outer portion and the minute cavities are formed at the central portion by the lack of eutectic liquid and hence the mean composition at the center becomes rich in Zn. KT(5a)

The World's Most Powerful Microscope. F. F. Lucas. *Journal of the Society of Motion Picture Engineers*, Vol. 16, April 1931, pages 445–456.

Koehler of the Zeiss Works developed, about 30 years ago, a microscope using ultra-violet light. It was forgotten until the Bell Telephone Laboratories developed another recently. With the microscope it is possible to obtain brilliant images of metallurgical specimens magnified 5000–6000 diameters. The ordinary type microscope is limited to 1000–1500. Gives a full account of construction and operation of the microscope. RHP(5a)

Chrome-Nickel Alloys. V. N. Krivobok. *Foundry Trade Journal* Vol. 43, Nov. 27, 1930, page 374.

Abstract of report read before the Metallurgical Advisory Board of the Carnegie Institute of Technology and the Pittsburgh Experiment Station of the U. S. Bureau of Mines. The paper was entitled: "Chrome-Nickel Alloys—Constitutional Diagram of 18% Chromium-Iron Alloy with Variable Composition of Nickel and Carbon. Disintegration of 18–8 Alloys." Alloys investigated ranged from 0.046 to 0.34% C, 17.20 to 18.38% Cr and 7.82 to 8.57% Ni. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 142. VSP(5a)

The Copper-Magnesium Alloys. Part IV. The Equilibrium Diagram. W. R. D. Jones (University College Cardiff). *Institute of Metals, Advance Copy* No. 574, Sept. 1931, 25 pages.

Previous work on the Cu-Mg system is reviewed. The equilibrium diagram was studied by thermal and microscopic methods. The alloys were melted in a vacuum and the freezing points determined as they cooled in the vacuum. During solidification, the furnace was shaken to prevent excessive segregation. At ordinary temperatures, about 0.02% Cu is soluble in Mg and 2.0–2.2% Mg in Cu. The compounds Mg_2Cu and $MgCu_2$ exist and do not form solid solutions. The Mg-rich solution forms a eutectic with Mg_2Cu at 30.7% Cu with a melting point of 485° C. The 2 compounds form a eutectic containing 65.4% Cu and melting at 552° C. The compound $MgCu_2$ and the Cu-rich solution form a eutectic at 90.3% Cu and 722° C. Contains 12 references. JLG(5a)

Dilatometric Study of Chromium-Nickel-Iron Alloys. Vsevolod N. Krivobok & Maxwell Gensamer. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 434, Sept. 1931, 23 pages.

The effects of cooling to subatmospheric temperatures on the room temperature properties of steels containing 18% Cr and varying amounts of Ni were studied. The steels contained various C contents. A mixture of solid CO_2 and acetone gives a sufficiently low temperature to produce hardening in some alloys. The hardness produced in some quenched austenitic alloys was as high as 50 Rockwell C. A dilatometric study of the steels from the low temperature to heat treating temperature proved that the hardening at low temperature was due to the decomposition of the austenite. The transformation at low temperature was very rapid. Both C and Ni tend to lower the temperature at which austenite is decomposed. The results of the dilatometric study of the steels are discussed in detail. Contains 5 references. JLG(5a)

Physico-Chemical Study of the Gold-Copper Solid Solutions. N. S. Kurnakow & N. W. Ageew. *Institute of Metals, Advance Copy* No. 576, Sept. 1931, 17 pages.

Previous work on this alloy system is reviewed. Resistance measurements and a dilatometric study proved the existence of the compounds AuCu and $AuCu_3$, which form from the solid solution at a temperature of 425–450° C. They both form solid solutions, the $AuCu_3$ existing from 22 to 40 atomic % Au, and AuCu from 42.5 to 70 atomic % Au. The formation of both compounds can be retarded by rapid cooling. The formation of the compounds is accompanied by a marked decrease in volume. 34 references. JLG(5a)

The System Iron-Nitrogen. (Beitrag zur Kenntnis des Systems Eisen-Stickstoff.) W. Köster. *Archiv für Eisenhüttenwesen*, Vol. 4, May 1931, pages 537–539; *Stahl und Eisen*, Vol. 51, June 11, 1931, page 740.

The author critically reviews the recent investigations of the Fe-N system by O. Eisenhut and E. Kaupp (*Zeitschrift für Elektrochemie*, Vol. 36, 1930, pages 392–404) and by E. Lehrer (*Zeitschrift für Elektrochemie*, Vol. 36, 1930, pages 460–473) and gives the results of his own investigations. The results of the above mentioned authors are in agreement but for the concentrations of 4–6% N with the transformations between the phases γ, γ' and ϵ. Eisenhut and Kaupp give a peritectoid transformation, Lehrer, a eutectoid one. In microscopically examining the outer layers of nitrided electrolytic Fe (8 hrs. at 650° in ammonia), the author found them, too. This result is also borne out by the results of some heat treating tests. The eutectoid with the low N content, Braunite, is transformed to martensite and austenite in quenching from 600° C. The eutectoid with the higher N content is still unchanged by quenching from 700° C. In 12 micrographs, it is shown that the relative behavior of the homogeneous Fe-Ni phases α, γ, γ' and ϵ, its transformations and changes of solubility at slowly cooling, as well as the formation and decomposition at quenching and tempering can be microscopically studied. These observations are in agreement with those of Eisenhut, Kaupp and Lehrer. Up to 3% N, Fe-N alloys show a behavior similar to Fe-C alloys. GN(5a)

A Study of the Constitution of the Iron-Tin Alloys. C. A. Edwards & Preece (University College, Swansea). *Iron & Steel Institute, Advance Copy* No. 8, Sept. 1931, 14 pages.

Early work on the Fe-Sn system is reviewed. The existence of 3 compounds was proved. Fe_2Sn is stable between 760° and 900° C., but can react with Sn at 800° C. to produce the compound FeSn. FeSn is stable at all temperatures below 800° C., but reacts with Sn at 496° C. to form $FeSn_2$. $FeSn_2$ exists below 496° C: on heating, it decomposes into FeSn plus a Sn-rich liquid. No polymorphic changes occur in $FeSn_2$ as suggested by Wever and Reinecken. Approximately 18% Sn is soluble in Fe at 760° C. Below this temperature, the solubility decreases to about 10% at 300° C. 2 references. JLG(5a)

The Iron-Carbon System. (Le système Fer-Carbone.) L. Dupuy. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 283–289.

Includes discussion and 11 figures. Review of the history of the Fe-C diagram with a "1930" diagram. This was criticized in discussion for not representing the fact that the solubility of C in α-iron changes with temperature so as to allow precipitation hardening. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 142. HWG(5a)

Structure and Properties of Pearlite. (La perlite, sa structure et ses propriétés mécaniques.) N. T. Belaiew. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée*, Section de Métallurgie, 6 session Liege, June 1930, pages 257–261.

Discusses relation of mechanical properties to the interlamellar distance between the cementite layers of pearlite. See *Metals & Alloys*, Vol. 2, July 1931, page 127. HWG(5a)

The Diffusion of Tin into Iron with Special Reference to the Formation of Columnar Crystals. C. O. Bannister & W. D. Jones. *Iron & Steel Institute, Advance Copy* No. 3, Sept. 1931, 23 pages.

The diffusion of Sn into Fe was studied by heating iron cylinders containing a plug of Sn to various temperatures, sectioning, and examining the resulting microstructures. The behavior depends on the temperature. Below 900° C. little change in the Fe could be observed. Above 900° C., and below A_4, a band of columnar crystals is formed. Columnar crystals have been observed when other metals that form a closed γ-loop diffuse into Fe, and when steel is decarburized at certain temperatures. The formation of the columnar crystals results from the transformations of γ to α Fe at a constant temperature as the Sn content of the Fe increases. Columnar crystals are therefore not formed below the A_3 temperature. An experiment indicated that they were likewise not formed by diffusion above the A_4 temperature. The rates of diffusion for several temperatures were studied and formulae derived for expressing the rate of diffusion as a function of the temperature. 24 references. JLG(5a)

On the Structure of Nodular Troostite. N. T. Belaiew. *Iron & Steel Institute, Advance Copy* No. 4, 1931, 19 pages.

From a study of high-magnification micrographs, it was found that the interlamellar distance in troostite is about 100 $\mu\mu$. Troostite under high magnification has the appearance of pearlite under a lower magnification. Troostitic nodules differ in appearance from pearlite in having a fan shaped structure. The various structures found in eutectoid steel and their hardness values are discussed. It is concluded that even though each contains structures common to all of the structures observed in eutectoid steel pearlite, sorbite and troostite should be considered as distinct and different constituents of steel. Contains 30 references. JLG(5a)

Some Important Factors Controlling the Crystal Macrostructure of Copper Wire Bars. L. H. DeWald. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 429, Sept. 1931, 12 pages.

The influence of the following conditions on the macrostructure of Cu wire bars were studied: (1) temperature of metal as cast, (2) casting speed, (3) temperature of mold, (4) time the bar remains in mold after solidification before quenching, and (5) circulating volume of quenching water and its temperature. Conditions 1 to 3 influenced the structure, but 4 and 5 did not. A fine equiaxed structure can be produced with low casting temperature, low mold temperature and slow pouring. Heating at the rolling temperature did not alter the macrostructure. In processing bars of coarse and fine grained Cu to form 24 gage wire, no differences could be found in the mill performance between bars of different grain size. It is stated, however, that tough-pitch Cu cast at low temperatures, and hence being fine grained, is preferable for the production of fine wire. 11 references. JLG(5a)

Copper-Nickel-Silicon Alloys, Rich in Copper. (Sulle leghe rame-nickel-silico, ricche in rame.) E. Crepaz. *La Metallurgia Italiana*, Vol. 23, Aug. 1931, pages 711–716. 7 figures, 6 references.

Previous work of Smith on solid solubility of Si in Cu was confirmed, and the study extended to ternary alloys of Cu containing up to about 7% Si and 9% Ni. Thermal analysis, hardness and microscopic structure were determined. Results plotted on a ternary diagram show that at 880° C., alloys with 1% Ni, 3% Si to 6% Ni, 1% Si are homogeneous solid solutions while the solid solubility at 500° C., probably falls to around 2% Si with 1% Ni and ½% Si with 2% Ni. The iso-hardness curves on the ternary diagram show an inflexion at compositions corresponding to the ratio 2 Ni : 1 Si indicating that when sufficient Ni is present to give that ratio, the Si is present as Ni_2Si. HWG(5a)

Eutectic Castings. (Fonte eutectique.) Bettinger. *Revue Fonderie Moderne*, Vol. 25, 1931, pages 267–270.

Formulae are developed which allow the chemical composition of a eutectic casting (an alloy which is defined by the temperature at which the entire solution solidifies instantaneously and completely) to be calculated. Tables are made up from which, for any desired thickness of material, these compositions can be taken. The tensile strength can also be calculated from the chemical composition for which the formula and an example are given. Ha(5a)

Occurrences during the Formation of the Martensitic Structure. (Ueber die Vorgänge bei der Ausbildung des Martensiticgefüges.) H. HANEMANN, K. HERRMANN, N. HOFMAN & A. SCHRADER. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 479–484; *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 646–647.

The authors summarize their results as follows: (1) The structural component η which may be detected microscopically corresponds to the tetragonal phase of hardened steel. (2) Pseudomorphoses are formed in quenched steel, (a) in the tempering, the structure of the δ-phase changes without showing up a change of shape in the micrograph, (b) the η-phase shows an individual crystal type but X-ray investigations did not reveal a structure which differed from α-iron. This indicated the presence of a pseudomorphose. (3) Cementite is formed only at the second transformation of martensite. (4) The state between the first and second transformation of martensite, called ξ, contains a distorted α-iron lattice with interspersed and adsorbed C atoms. GN(5a)

Carbon Content of the η-Phase. (Ueber den Kohlenstoffgehalt in der η-Phase.) H. HANEMANN. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 485–486; *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 647–648.

If quenched steel is tempered above temperatures of the second transformation of martensite (about 300° C.), it is composed of a matrix of α-iron with embedded, very fine globules of cementite. In tempering for a longer time, it depends upon the particle size of the cementite in the austenite and the η-needles whether C diffuses from the η-needles into the austenite or vice versa. The following experiment was made to determine the C content of the η-phase. A quenched 1.67% C steel and composed of austenite and η-needles was heated at 930° for 10 mins. and then quenched in water. The structure now shows a C distribution corresponding to the original quenched structure. Areas corresponding to the original η-needles only contain martensite, whereas the areas corresponding to the original austenite show martensite and cementite. Such a structure would not be possible if the η- needles, after the first quenching, had not contained a C content of about 1.1%. There obviously exists a difference between the C content of the austenite and the η-martensite needles. GN(5a)

Etching with Alkaline Sodium Picrate Solution and Its Use to Detect the Occurrences in Tempering Quenched Steel. (Die Aetzung mit alkalische Natriumpikratlösung und ihre Anwendung zur Erforschung der Anlassvorgänge im gehärteten Stahl.) H. HANEMANN & A. SCHRADER. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 475–477; *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 645–646.

Etching temperatures between 40–60° C. are suitably used in etching with alkaline solutions of sodium picrate to detect the various tempering structures. The velocity of etching differs for the various structural components. FeC_3 is always etched by picrate. Ferrite, austenite and the η-phase are not colored by picrate. Since the tempering effect of the η-phase has a noticeable velocity even at 70° C., and the η-phase is then darkened, it is advisable to etch at first at room temperature in observing structures containing the η-phase. The ξ-component etches much more slowly than the Fe_3C. In etching for 40 mins. at room temperature, Fe_3C is darkened whereas the ξ-component remains bright. The δ-phase is still less attacked than the ξ-phase. The best etching temperature to distinguish ξ and δ is between 50–60° C. Austenite is attacked when the steel is heated above about 250° C. the ξ-phase is homogeneously etched till the occurrence of the second transformation of martensite. After the occurrence of this transformation, a heterogeneous picture will be seen. GN(5a)

Atlas Metallographicus. H. HANEMANN & A. SCHRADER. Gebrüder Bornträger, Berlin, 1930. Paper, 8 × 11 inches, Section 8, plates 57–64. Price 13.20 RM. Section 9, plates 65–72. Price 15.60 RM.

The latest published sections of this marvelous standard work are devoted to the study of some occurrences which are of extreme importance for the ferrous metallurgist. They are an excellent study of the effect of heat upon the structure of steel. In section 8, plates 57–59 show the structures of steel as affected by carbon content and cooling velocity; illustrations are included which show the variation of grain size with the variation of the conditions mentioned above. Plates 60 and 61 are devoted particularly to the influence of the cooling velocity upon the crystallization of ferrite as well as pearlite. Plates 62–64 deal with banded structure and the means of eliminating this phenomenon.

Section 9 (plates 65–72) continues the occurrences shown by the photographs of Section 8 in more detail and gives some illustrations of problems which can be of great concern to the steelmaker. Reference may be made to only the 8 pictures of plate 69 which the author brings under the heading "The origin of abnormal pearlite." This abnormal pearlite appears in low C steels, possibly below 0.10% C, at low cooling velocities and shows large crystals of cementite surrounding the few areas of lamellar pearlite. This cementite, though in appearance like the tertiary cementite which is caused by the slight solubility of C in α-Fe, is different from this one and generally does not appear in low carbon steels of a larger grain size. Whereas the intersticial cementite caused by the abnormal crystallization of pearlite can be eliminated by rapidly cooling the steel from a higher finishing temperature. A study of these pictures may be recommended to anyone who has much trouble in obtaining a proper structure in low carbon steel rods.

The next sections of the Atlas Metallographicus are announced as being devoted to the changes of structure due to cold work and recrystallization and the structures of non-hardened carbon steel shall then be concluded.

Looking over again all the sections which have been published so far, one feels as though a picture gallery had been visited and it is no exaggeration to say that each picture is a classic one. Time and study are important for a thorough appreciation of them.—G. Neuendorff (5a)-B-

Another Etching Reagent for Aluminum Alloys. (Nog een etsmiddel voor aluminumlegeeringen.) J. G. S. DE HAAN. *De Gieterij*, Vol. 5, Apr. 1931, pages 50–51.

For silumin the author obtained good results by polishing first with a 10% "solution" of alumina No. 1, followed by a polish-attack with a 5% solution of alumina No. 2 containing about 0.05% $FeCl_3$. HSvK(5a)

The Investigations of G. Tammann on the Constitution of Alloys. (Die Forschungen G. Tammanns über die Konstitution der Legierungen.) G. GRUBE. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 137–138.

Discusses the research work of Tammann and his co-workers done on the constitution of alloys and emphasizes the development of the thermal analysis and constitutional diagrams. EF(5a)

The Constitution of Zinc Lithium Alloys. (Die Konstitution von Zinc-Lithium-Legierungen.) W. FRAENKEL & R. HAHN. *Metallwirtschaft*, Vol. 10, Aug. 14, 1931, pages 641–642.

Zn alloys containing up to 9% Li were melted in porcelain crucibles lined with magnesia under a protective flux of LiCl and Li_2CO_3. Zn was melted first and Li introduced under the surface to prevent loss by oxidation. Cooling curves were determined and the alloys were examined microscopically. The melting point of Zn drops to 402° at the eutectic with 0.6% Li, then rises at first rapidly then more moderately up to about 6% Li. Evidence points to the formation of the compound Zn_2Li_2. The higher Li alloys are brittle and tarnish rapidly. In the photomicrographs, the 0.5% Li shows primary Zn crystals and a small amount of eutectic. The 0.75% Li alloy is almost all eutectic and the 1% Li alloy shows primary crystals of the compound. CEM(5a)

Radiographic comparison of malleable iron castings made in different foundries. (a) Shows shrinkages over practically full length (b) shows no imperfections, indicating correct foundry practice.

Fissures · Cracks · Blowholes?

Why not find out by X-Ray first?

EVERY engineer knows with what distressing frequency castings contain defects of one sort or another. Often visible from the surface . . . as often not. Many important and expensive castings are scrapped because of doubt. No one can afford to take the risk!

A simple X-Ray examination would settle all doubt in many cases. Leading firms are finding astonishing savings in using this method of inspection. Why don't you investigate? Our booklet "Industrial Application of the X-Ray" is well worth a reading. Write for a copy. For convenience, use coupon.

Structure & X-Ray Analysis (5b)

Comments on Crystal Plasticity. (Bemerkungen zur Kristallplastizität.) W. Boas & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalt*, Sonderheft 10, 1930, pages 105–108.

An analytical discussion of shearing strength and shearing coefficients for different kinds of lattice structures. 22 references. Ha(5b)

The Value of X-Ray Inspection to Electric Arc-Welding. H. R. Isenburger. *Welder*, Vol. 2, Aug. 1931, pages 7–14.

The principal undesirable conditions in electric arc-welds revealed by radiographic examination are the following: (1) the improper fusion at scars between weld and parent metal, that is, no penetration; (2) laps not fused between layers of weld metal; (3) gas inclusions more or less numerous throughout the weld zone; (4) shrinkage cracks developed during or after welding. No penetration and laps are usually characterized by slag inclusions which may actually be slag but are usually a fine skin of oxide. Shrinkage cracks occur very seldom. Several examples of defects revealed in photographs are included. It is recommended that each welder learn to check his work with X-ray pictures. The cost of operating an X-ray installation is approximately $3.00–$5.00/hr., exclusive of investment. Ha(5b)

The Quantum Theory of Dispersion in Metallic Conductors. R. de L. Kronig. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 255–265.

In a previous paper (Kronig, *Proceedings of the Royal Society*, Vol. 124, page 409, 1929) the theory of dispersion in metallic conductors was formulated more precisely for the case of the temperature agitation of the metallic lattice. The absorption bands which dominate the optical behavior of metals in the visible and ultra-violet part of the spectrum are discussed in detail. An extension of the theory for the infra-red region of the spectrum, where the average time between 2 collisions of an electron with the metallic lattice is comparable with the period of the radiation is given. Explicit formulae for the index of refraction and the coefficients of extinction and reflection are derived which go over into the classical expressions of Drude in the limit $\gamma = 0$. The experimental data are compared with the theoretical results and found to give satisfactory agreement. The possibility of obtaining valuable information about the surface layers of metals from the optical constants is pointed out, as well as the desirability of measuring the temperature dependence of these constants in the infra-red. WAT(5b)

X-Ray Investigation on Copper-Arsenic Alloys. Nobuyuki Katoh. *Bulletin Chemical Society of Japan*, Vol. 5, Sept. 1930, pages 275–282.

Data are given for powder X-ray photograms of CuAs alloys with 19.6% As, 30.86% As cooled slowly and 30.86% As quenched from 630°. The dimensions of the elementary cube for the upper and lower limits of homogeneity for β Cu with approximately 29.1% As are calculated. WHB(5b)

Advances in Method and Application of X-Ray Investigation. (Fortschritte der Röntgenforschung in Methode und Anwendung. Ergebnisse der Technischen Röntgenkunde. II.) F. Körber & E. Schiebold, *et al.* Akademische Verlagsgesellschaft m.b.H., Leipzig, 1931. Cloth, 6 × 9 inches, 326 pages. Price 38 RM.

In *Metals & Alloys*, Volume I, page 918 appeared a review of a volume, which was designated as the first of what should prove to be a very interesting and valuable series presenting a cross section view of X-ray science as applied to the testing of materials at the present time. The second or 1931 volume of this series has now appeared and the promise displayed by the previous member of the series is more than substantiated. Twenty chapters are presented, again by outstanding authorities, as follows:

Researches with X-rays on Molecular Arrangement in Liquids by Debye and Menke.
X-ray Diffraction Photographs of Liquid Crystals in Magnetic and Electric Fields by Herrmann.
Roentgengraphic Researches on Fats, Oils and Greases by Trillat.
The Interferometric Research on Molecular Structure of Organic Compounds by Mark.
Interference Phenomenon of Electrons in Crystals by Rupp.
Modern Methods of Crystal Structure Analysis by Schiebold.
The Use of General Radiation in Fine Structure Research by Regler.
Roentgengraphic Determination of Size and Form of Submicroscopic Crystals by Brill.

The Dependence on Temperature of the Photographic Process by Eggert.
Intensity Measurements on Deformed Crystals and Mixed Crystals by Hengstenberg.
Crystal Chemistry and the X-ray Method by Goldschmidt.
New Results of X-ray Investigation in the Inorganic Field by Gottfried.
Results of Modern Investigations on Metals by Bernal.
The Classification of Iron Alloys by Wever.
Changes of State under Pressure of Alloys by Sachs
Quantitative X-ray Spectrographic Analysis with Secondary Rays by Hevesy.
X-rays and Chemical Combination by Stintzing.
New Physical and Economic Principles of Technical Radiography by Berthold.
Densographic Interpretation of X-ray Shadow Pictures of Pieces of Metal by Schwarz.
Diascopic Researches with X-rays by Lefring.

Anyone who is interested in X-ray developments, particularly from the chemical and industrial point of view is more and more impressed by the great service which is being given in these condensed and inspiring accounts of the most recent results in the numerous fields of investigation. The attempt to keep in touch with the almost overwhelming number of original papers now being published is discouraging, and the only hope, therefore, is to be found in critical condensed accounts of each subject by men best qualified in each field. The reviewer is frank to confess that he found this new volume as hard to put down as an excellent novel. It is unquestionably the best method of becoming acquainted with the very newest developments. The value and excellence of this series devoted to reporting the progress of technical X-ray science are assured and Volume III can come none too soon. It is to be hoped that the collection can be made even more international in character, although it is to be observed that a Swiss, a Frenchman and an Englishman have contributed important chapters in the present volume. It is a distinct pleasure to recommend it as a necessary addition to the equipment and knowledge of anyone who is even remotely interested in x-rays as a great research tool.—G. L. Clark (5b)-B-

An X-Ray Radiation Suitable for Determining Small Deviation in the Lattice Constants of Alpha-Iron. (Eine zur Bestimmung von kleinen Aenderungen in der Gitterkonstanten von alpha-Eisen geeigneten Röntgenstrahlung.) A. E. van Erkel & W. G. Burgers. *Zeitschrift für Metallkunde* Vol. 23, May 1931, pages 149–151.

Paper suggests the utilization of Co K_α radiation ($\lambda K_{\alpha 1}$ = 1.78578 A.U. and $\lambda K_{\alpha 2}$ = 1.79006 A.U.) for determining the space lattice of α-Fe. Exceedingly distinct interference lines are secured due to a selective absorption of the $K\beta$ radiation. The experimental facilites are described and the method of determining small deviations of the space lattice constants due to impurities or elastic stresses is fully outlined. EF(5b)

USEFUL BOOKS

ZIRCONIUM AND ITS COMPOUNDS

Francis P. Venable — *A. C. S. Monograph No. 5*

173 Pages **$3.00**

The only book in English completely covering the occurrence, preparation, properties and applications of this element and its compounds. A list of important patents and an extensive bibliography are appended.

MOLYBDENUM, CERIUM AND RELATED ALLOY STEELS

H. W. Gillett and E. L. Mack — *A. C. S. Monograph No. 22*

299 Pages **Illustrated** **$4.25**

Describes the sources and chemical properties of the alloying materials and the physical and engineering properties of the alloy steels containing them.

TITANIUM, with Special Reference to the Analysis of Titaniferous Substances

William M. Thorton, Jr. — *A. C. S. Monograph No. 33*

262 Pages **Illustrated** **$3.75**

Following an introductory portion covering the occurrence, general chemistry and industrial applications of titanium, the author presents an exhaustive treatise on the detection and estimation of titanium in its various associations, having particularly in mind the requirements of the practical analyst.

PROTECTIVE METALLIC COATINGS

Henry S. Rawdon — *A. C. S. Monograph No. 40*

277 Pages **Illustrated** **$4.25**

An up-to-date survey of the field of corrosion prevention, or retardation, particularly of iron and steel, especially useful to the engineer, manufacturer, metallurgist and chemist. The various coating methods—hot-dipping, cementation, metal spraying, electroplating, alloying, chemical treatment, etc.—are described in detail, as are the coatings produced by these methods using zinc, tin, copper, nickel, chromium and other metals. Methods of testing such coatings are given and an extensive bibliography is appended.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Magnetic Inspection Achievements to Date. LEWIS S. REID. *Metal Progress*, Vol. 19, June 1931, pages 40–44.

The author briefly describes what happens when magnetic influences are impressed upon steel. The merits of direct and alternating current for magnetic testing are discussed. One circuit for use of alternating current in magnetic analysis is described and its applications in non-destructive testing described. WLC(6)

Magnetic Analyses. Report of A.S.T.M. Committee A-8. R. L. SANFORD, Chairman. *Preprint* No. 15 for June 1931 meeting, *American Society for Testing Materials*, 1 page.

Brief progress report. No technical data. HWG(6)

Power-Bending Diagrams of Notch Impact Tests. (Kraft-Durchbiegungs-Schaubilder von Kerbschlagversuchen.) R. MAILÄNDER. *Stahl und Eisen*, Vol. 51, Apr. 2, 1931, page 437.

Abstract of paper by T. Asano in Memoirs Ryojun College of Engineering (Port Arthur, South Manchuria). The author describes a new method to determine the forces brought about in notch-impact specimens during the test. For this purpose the specimens are clamped in an Izod machine so that the notch is somewhat outside of the clamp. A mirror is attached to the specimen between notch and clamp. A light ray thrown upon this mirror records the deformation of the specimen on a photographic plate as indicative of the force of impact. R. Mailänder discusses in his abstract some objections to the above simple method. GN(6)

Internal Stresses in Steel. Correspondence from E. W. EHN, Cannstatt, Germany. *Metal Progress*, Vol. 20, Aug. 1931, pages 88–89.

The writer reports work on a new method of determining internal stress in quenched steel. WLC(6)

Strain Measurements in the Reinforcement for the Natural History Building. W. C. LYON, H. L. WHITTEMORE, A. H. STANG & L. R. SWEETMAN. *Bureau of Standards Journal of Research*, Vol. 6, Feb. 1931, pages 183–194.

An interesting example of the use of the Whittemore strain gage in the measurement of stresses in indeterminate structures is presented in the reinforcement of the dome over the rotunda of the Natural History Building of the National Museum. A slight outward movement of the brick piers supporting the dome caused cracks to develop along the joints in the masonry and in the stone arches under them. To reinforce the structure the pendentives were surrounded by a steel framework. Inwardly directed forces were exerted on the masonry by many screw jacks, to prevent further movement. To control the jacking operation, readings were taken on a large number of gage lines on the frame work, using a Whittemore strain gage. The stress in the frame work was computed from these readings. Approximately the desired stress in each member was obtained. The safety of the dome and its supporting structure was thereby assured. The use and construction of the strain gage is described in detail. WAT(6)

Metallurgical Creep. A. G. HINTON. *Engineer*, Vol. 151, May 8, 1931, page 506.

A letter to the editor which sets forth an empirical formula which more accurately expresses the relation between stress and log creep strain per unit time than those heretofore. The equation is:

$$C = K\frac{(p-a)^3}{(b-p)^2}$$

where C = creep (strain per unit time)
p = tensile stress
K, a and b are constants which depend upon the temperature
a = stress for zero secondary creep
b = stress for infinite secondary creep

K is taken as the reciprocal of a quantity akin to viscosity. The formula, if true, implies that there is a definite limiting creep stress, a, and the fact that the formula agrees closely with experiments affords strong evidence that such a limiting creep stress actually exists. Secondary creep becomes infinite when p = b and zero when p = a. WAT(6)

A New Method for Testing Deep Drawing Sheets. (Sur une novelle methode d'essai des toles a l'emboutissage.) JEAN COURNOT. *Revue de Métallurgie*, Vol. 28, pages 254–258.

A description of the method proposed by Siebel and Pomp (*Stahl und Eisen*, Vol. 52, Dec. 26, 1929, pages 1866–1868) pointing out its advantages in comparison with the usual cup test. See *Metals & Alloys*, Vol. 1, May 1930, page 524. JDG(6)

Critical Review of Testing Methods for Welded Seams. (Kritische Betrachtung der Prüfverfahren für Schweissnähte.) H. KEMPER. *Autogene Metallbearbeitung*, Vol. 23, July 1, 1930, pages 199–205; July 15, 1930, pages 218–226; Aug. 1, 1930, pages 234–241; Aug. 15, 1930, pages 253–258.

A very exhaustive discussion deals with the different methods of testing the quality of a weld. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 144. Ha(6)

The Testing of Materials by Means of Magnetic Methods. (Werkstoffprüfung mittels magnetischer Arbeitsverfahren.) E. GEROLD. *Stahl und Eisen*, Vol. 51, Apr. 2, 1931, pages 428–432.

Abstract of a paper in *Mitteilungen Forschungsinstitut der Vereinigte Stahlwerke*, Dortmund, Vol. 2, 1931, No. 2, pages 23–37. 65 references. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 172. GN(6)

Dynamic Investigation of Railroad Bumpers. (Dynamische Untersuchung von Eisenbahnpuffern.) P. LANGER & W. THOME. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Aug. 8, 1931, pages 1013–1018.

The basis for the comparison of bumpers with helical springs, friction springs and liquid buffers is developed and the manner in which the behavior of the buffers can be determined is shown. The tests were made with railroad cars running against the buffer with a definite speed from which the energy acting on the buffer could be calculated and the compression of the buffer measured. Numerous curves illustrate the tests. 6 references are given. Ha(6)

Tests on Automobile Bearing Springs in the National Physical Laboratory. (Versuche mit Automobil-Tragfedern im National Physical Laboratory.) E. LEHR. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 2, Aug. 1931, page 287–290.

Determination of the bending strength of laminated springs; endurance testing of the whole automobile bearing spring; testing the deflection of the spring while driving the car on all kinds of roads and at various speeds. MAB(6)

The Calculation of Helical Springs of Round Wire. E. HONEGGER. *Brown Boveri Review*, Vol. 18, Mar. 1931, pages 120–125.

The values for the greatest shear and normal stresses in transverse section of loaded helical springs are calculated. Both stresses occur at the innermost fibre of the spring coil. Both stresses act in the transverse section of the spring wire; an equal shear stress also acts in the longitudinal section. Discrepancies are important. The results of calculation in the 2 examples quoted agree very well with direct measurements. The method of calculation is simple enough for technical calculation, and is particularly applicable in the case of highly stressed close-coiled springs. MAB(6)

Crystallographic Investigation of Some Mechanical Properties of the Metals. I. The Plastic Bending of Crystal Plates. II. The Yield Point of Aluminum Crystals with Respect to Bending. III. On the Damping of Lateral Vibration of Aluminum Crystal Plates. IV. On the Internal Slip of the Metal. V. Fatigue of Metals under Alternating Torsion. Y. KIDANI. (In English.) *Journal of the Faculty of Engineering, Tokyo Imperial University*, Vol. 19, No. 1, June 1930, pages 1–15; No. 5, Feb. 1931, pages 107–129; No. 7, May 1931, pages 177–190.

Parts I, II. Asterism in Laue photographs of bent aluminum single crystals is due to slip. The yield point depends on the crystal orientation. The modulus of elasticity of the single crystals (8.5 × 10'' dynes) agrees with that of ordinary aluminum. The treatment is mathematical. Parts III, IV. The logarithmic decrement of single crystals of Al is not altered by crystal orientation at small amplitudes, but varies with orientation if the amplitude is so high that slip occurs. The modulus of elasticity calculated from the logarithmic decrement curves was found to be the same whatever the orientation. (The figure, 7.04 × 10'' dynes does not agree well with that found in Kidani's previous work.) In hard rolled Al, annealed at various temperatures, the logarithmic decrement falls rapidly when the metal has been annealed sufficiently to soften it. In 0.35% C steel, quenched and tempered at various temperatures, the decrement falls as the structure changes from martensite to troostite and then rises rapidly as sorbite appears. It falls again when the steel is annealed to a pearlitic structure. More energy is dissipated by sorbite than by the other structures. Annealed Al, Cu, Ni and 0.35% C steel were work-hardened to different degrees by tensile stretching and the logarithmic decrement determined. The decrement changes after the yield point has been exceeded, but the curves depend on the direction in which the specimen is cut in respect to the direction of working and on the amplitude used in the decrement test. The types of curves shown for the different metals vary widely. Part V. The title is rather a misnomer as no endurance limits were obtained. Three or four repeated torsion tests were made on each of 4 materials, annealed steels of 0.1, 0.3 and 0.6% C, and annealed copper, at such high stresses that fracture occurred in 200,000–270,000 cycles or less for the steels and 740,000 or less for the copper, save for one test on 0.1% C steel on which the plot indicates that it ran to about 400,000 cycles, but it is not stated whether the test was carried to fracture. The angular amplitude for a given torsional moment after varying numbers of cycles of repeated torsion is plotted. At the higher stresses it decreases sharply, then the change becomes less until, just before fracture, it rises sharply. As the stress is lowered the initial dip becomes smaller and the amplitude then remains nearly constant till just before fracture. Apparent constancy may be reached well above the endurance limit. Torsional damping tests were applied, at one stress only in each case, to 0.3% C steel and to copper. Plotting logarithmic decrement against number of cycles of repeated torsion before the damping test, the decrement rises for a while and then falls. The rise is assumed to correspond to the work-hardening stage (the tests were made at high stresses) and the fall to the "fatigue stage." One of the author's conclusions is that the rate of damping gave significant information as to the degree of fatigue. Since the tests were so few in number and the stress used so far above the endurance limit (fracture in 80,000 cycles for steel, 150,000 for copper) the conclusion is far too sweeping for acceptance without much further evidence. HWG(6)

Permeability Measurements on Iron in Case of D. C. Premagnetization. (Messungen der Permeabilität des Eisens bei Gleichstrom-Vormagnetisierung.) E. HÖLLER. Dissertation, Technische Hochschule Stuttgart, 1928, 23 pages.

The present investigation largely pertains to the formula of Spooner (*Journal American Institute Electrical Engineers*, 1923, page 42) giving the dependence of the additional permeability μ_Δ on the normal permeability $\mu_{Bm} = \frac{B_m}{H_m}$ and on the changes of the electrical field ΔB by alternating current: $\mu_\Delta = \mu_{Bm}(a + b \cdot \Delta B \cdot 10^{-3})$. New values for the constants a and b in the formula of Spooner were experimentally determined which yield more accurate results with pure iron and Si-sheets, whereas Spooner's constants are applicable best for magnetic and ordinary steel sheets. It was established that below 2000 Gauss $\mu_\Delta = \mu_{Bm}$. The constants a and b were also determined for the range of 150–2,000 Gauss. It was furthermore proved that the formula of Spooner is also applicable for superimposed A. C. of 50 Hertz frequency. The latter measurements were in fair agreement with corresponding experiments carried out with direct current. EF(6)

The Deformation of Metals under Prolonged Loading: Part I. The Flow and Fracture of Aluminium. HANSON & M. A. WHEELER. *Engineer*, Vol. 151, Mar. 27, 1931, pages 340–341; discussion *Engineering*, Vol. 131, Mar. 20, 1931, pages 383–384.

Abstract of paper read before the Institute of Metals, Mar. 12, 1931. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 144. LFM(6)

The Elastic Limit of Steel Plates. R. H. GREAVES. *Proceedings Cleveland Institute of Engineers*, 1930–31, Feb. 1931, pages 110–135.

The elastic limit of steel plates is discussed in relation to the usual methods of testing laid down in specifications. Determination of the true elastic limit involves very accurate and delicate measurements and its value is influenced to a high degree by slight differences in the previous treatment of the material of the test piece. The following conditions, among others, depress the observed elastic limit: (1) non-axial loading, (2) a bent test piece, (3) testing immediately after any form of deformation, that is, testing immediately after straightening by bending or by pulling, (4) straightening by bending in one direction only, even after subsequent resting. The following raise the elastic limit: (1) straightening by pulling and subsequent resting, (2) straightening by reversed bending and subsequent resting, (3) in some instances, removal of the surface of the plate. To obtain consistent results in a specification test designed to judge a material, as nearly as possible, by its elastic limit, it is important that the test should be applied under strictly standard conditions. Methods for Determining the Roughness of Metal Surfaces. (Untersuchung verschiedener Methoden zur Bestimmung der Unebenheiten (Rauhigkeiten) von Metallflächen.) W. KIESEWETTER. Doktor-Ingenieur dissertation, Technische Hochschule, Dresden, 1931, 71 pages, 29 figures. Bibliography of 25 references.

Profile maps of the irregularities of a metal surface finished by machining, polishing, lapping, etc., may be drawn in various ways. Among these are: gelatine or similar casts can be sectioned and photomicrographs made; reflection methods can be used; or a phonograph needle bearing a mirror can be made to traverse the surface and the irregularities be magnified by an optical lever system, and photographically recorded. Or the irregularities may be recorded by a diamond point which scratches a glass slide, this being enlarged by making a photomicrograph and projecting it. Of these and several other methods, the last 2 were found most generally useful.

Average roughness figures, and profiles, are given for a wide variety of finishes on steels of varying carbon content, cast iron, red brass and Lautal.—H. W. Gillett (6)-B-

Physical Testing of Copper and Copper-rich Alloys in the form of Thin Strip. MAURICE COOK & EUSTACE C. LARKE. (I. C. I. Metals, Ltd.) *Institute of Metals, Advance Copy* No. 565, Sept. 1931, 17 pages.

Seven references. The sheets tested were rolled by commercial methods to thicknesses of 0.060, 0.040, 0.020 and 0.010 in. They were tested as annealed, reduced 9, 28 and 60% by cold rolling. Consistent results were obtained by the tensile test in all but the 0.010 in. samples. Some of the 0.010 in. samples gave erratic results, probably on account of poor alignment in loading. Of the several hardness testing methods used the diamond pyramid was considered to be the most satisfactory. Cupping tests give an indication of the workability, but the results by different machines vary too greatly to permit the inclusion of this test in specifications. Several tables give the detailed results of the tests, which include tensile, Brinell (1 mm. ball—5 kg. load), diamond hardness (pyramid with 10 kg. load), Rockwell hardness for 100 kg. load—1/8 in. ball, 100 kg. load—1/16 in. ball and 60 kg. load—1/16 in. ball, Schuchardt and Schütte hardness, scleroscope, with 3 mm. steel ball and with diamond tipped hammer, Erickson ductility, Avery ductility and Olsen ductility tests. Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A. S. T. M. Research Committee on Fatigue of Metals.

The Endurance Strength of the High Quality Structural Steel St52. (Zur Frage der Dauerfestigkeit des hochwertigen Baustahles St52.) H. BUCHHOLTZ & E. H. SCHULZ. *Stahl und Eisen*, Vol. 51, July 30, 1931, pages 951–961.

Report of the Research Institute of the Vereinigte Stahlwerke, Dortmund. This investigation compares the endurance properties of the German structural steels, No. 37 and No. 52 and a 3% Ni steel. In testing smooth round bars, steel 52 showed an endurance strength by 50% higher than steel 37. Notches, holes and sharp changes in section increase the yield point and the tensile strength of all 3 steels but the alternating strength is essentially decreased. Very deep notches increase the yield point of the steels 37 and 52 to about 2.4 times the yield point of un-notched specimens. The alternating strength decreases to 40–50%. GN(6f)

Maximum Stress: Its Influence on Cost and Service Life of a Structure. EVERETT CHAPMAN. *Journal of the American Welding Society*, Vol. 10, Sept. 1931, pages 19–22.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Small areas of localized stress are causes of fatigue failures which fix the useful life of a structure. Photo-elastic examination lends itself readily to the determination of the location and magnitude of these sore spots, while its greatest value lies in checking the remedy. These areas of stress concentration occur at some change in contour. Contour changes should be gradual. Machine structures fabricated by welding are very likely to include many areas of high stress concentration. It is necessary in dynamically loaded structures to anneal the piece thoroughly after welding. Article includes photoelastic pictures showing relation of contour to stress concentration. TEJ(6f)

Endurance Strength of Welded and Soldered Bicycle and Motorcycle Frame Pipes. (Dauerfestigkeit von geschweissten und gelöteten Fahrrad- und Kraftrad-Rahmenrohren.) K. BAUMGAERTEL & K. BRUESER. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 204–208; Sept. 1931, pages 216–220.

A very comprehensive investigation of the resistance of bicycle frames built up of pipes to vibration stresses. The article must be referred to for the details of the results. All tests were made on the Foeppl endurance testing machine. Results are given in tables and micrographs. Ha(6f)

Endurance Tests of Acetylene Welds. (Ueber Dauerprüfungen von Azetylen-Schweissungen.) BAUMGAERTEL. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 6, 1931, pages 27–37.

Descriptions of the bending machines of Schenck, Foeppl and of the Woehler Institute, that of Foeppl-Heydekampf and the bending-oscillating machine of the Maschinenfabrik Augsburg-Nürnberg. The results of a number of tests are tabulated. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 172. Ha(6f)

Endurance Properties of Some Well-Known Steels in Steam. T. S. FULLER. *Preprint* No. 8, *American Society for Steel Treating*, Sept. 1931, 15 pages.

See "Endurance of Alloy Steels in Steam," *Metals & Alloys*, Vol. 2, Sept. 1931, page 193. HWG+WLC(6f)

The Effect of Surface Conditions Produced by Heat Treatment on the Fatigue Resistance of Spring Steels. G. A. HANKINS & M. L. BECKER. (National Physical Laboratory.) *Iron & Steel Institute, Advance Copy* No. 9, Sept. 1931, 42 pages.

Previous work had shown that the fatigue limit of heat treated springs was only a fraction of that found in polished specimens. Experiments were conducted to determine whether or not this effect was due to surface cracks or to decarburized surfaces. A Si-Mn and a Cr-V steel was used. No cracks could be found in oil quenched specimens, and it appeared as though surface cracks were not responsible for the lowered fatigue resistance. Intentionally decarburized specimens, however, had a low fatigue limit, and it was evident that decarburization could explain the lowered endurance values in specimens containing the surface resulting from quenching. Decarburization resulted from the ordinary heat treatment, and even this slight carbon removal halved the fatigue limit. Several methods for avoiding decarburization were tried. When small specimens were heated in a neutral or CO atmosphere for quenching their fatigue limit was as high as that for ground and polished specimens. As commercially practicable treatments, it was found that heating in graphite powder or in a NaCN bath were satisfactory. The latter method of heating resulted in a higher fatigue limit than that in polished samples, due to C or N absorption. Other salt baths containing some cyanide were fairly satisfactory. Fatigue tests were made both on rotating cantilever and reversed bending machines. Values are listed in an appendix. Contains 7 references. JLG(6f)

Raising the Endurance Limit by Surface Pressure. (Das Oberflächendrücken zur Erhöhung der Drehschwingungsfestigkeit.) PAUL BEHRENS. *Metallwirtschaft*, Vol. 10, May 29, 1931, pages 431–435.

Contains 2 references. A special apparatus was developed consisting of 4 rolls mounted on a framework by which uniform pressure can be exerted on metal bars. Samples of 4 steels, 3 brasses and Elektron metal were subjected to pressure and then tested for endurance limit. In every case, a considerable increase was obtained. The first steel showed an increase of 21% in endurance limit with 5 kg./roll pressure. With 40 to 60 kg., a maximum of 42 to 50% increase was obtained. In open-hearth steel the maximum increase was 29% at 15 kg./roll; in Cr-Ni steel 24% at 60 kg.; in Cr-Mo steel 12% at 80 kg. In the first brass 11.5 to 16% at 40 to 60 kg.; in the second brass 16 to 33% at 5 to 10 kg., but only 4% at 20 kg. In the third brass the increase was irregular. In Elektron, the maximum increase was 38% at 40 kg./roll. CEM(6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

The Cleaning of Metals Before and After Plating. OTTO H. LOVEN. *Metal Industry*, N. Y., Vol. 29, July 1931, pages 291–292; Aug. 1931, pages 338–340.

Correct cleaning is necessary for good chrome plating. Inhibitors such as calcined soot for brass and salt for steel, prevent the pickles from attacking the base metal after the scale is removed. Boiling hot water should be used to rinse off alkaline cleaning solutions. The subsequent tarnish film is removed by 5% cyanide solution for brass and 10% hydrochloric acid solution for steel. After plating, 2 rinses should be carried out in running water heated to 125–180° F. PRK(7a)

Nickel Plating for Mass Production. N. R. LABAN. *Chemical Age*, Vol. 23, Sept. 6, 1930, pages 14–15; *Electroplaters' & Depositors' Technical Society Preprint*, 1930, 8 pages.

In a paper before the Electroplaters' & Depositors' Technical Society, the author describes experiments on Ni deposition at high current density claiming advantages of speed and better quality deposits over Ni deposition at low current density. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 81. VVK+LCP (7a)

On the Throwing Power of the Solution for Electroplating. SEIJI KANEKO. *Journal Society Chemical Industry*, Japan, Vol. 34, Apr. 1931, page 135B.

A formula is made for the study of the throwing power of the solution for electroplating. A relation is deduced from the formula; the equation shows that the more uniform deposition is obtained by increasing the distance between electrodes, by decreasing the specific resistance or by increasing the value of $(\partial v_l/\partial I)$. MAB(7a)

The Separation of Tungsten from Gaseous Compounds and Its Application. (De Afscheiding van Volfraam uit Gasvormige Verbindingen en hare Toepassing.) J. A. M. VAN LIEMPT. J. Muusses, Purmerend, 1931. Paper, 6 × 9½ inches, 117 pages. Price 4.00 Fl.

Von Wilamowitz, in his recently published "Reminiscences," states that progress in science is greatly advanced by the publication of special publications more comprehensive than the usual run of journal articles. From this point of view, Dr. van Liempt who, for a number of years, has been on the staff of the Research Laboratories of Philips' Lamp Works at Eindhoven (Holland), has performed a distinct service by publishing a small volume dealing with the theory and practice of tungsten plating by decomposition of gaseous tungsten compounds.

The subject matter is divided into 6 chapters followed by a brief summary (in English). Chapter I contains a sketch of the electrolytic and the gaseous tungsten plating process. The author points to the fact that a complete, unbiased story of the electric lamp still has to be written. Chapter II deals with the preparation and properties of WO_2Cl_2, $WOCl_4$ and WCl_6. Van Laar's theory of the additivity of the van der Waal's constants $\sqrt{a}$ and b is applied to these and to other tungsten and molybdenum compounds. The results obtained indicate that W and Mo atoms have no external forces left in WCl_6, WF_6 and MoF_6. In Chapter III, the equilibria $W + 3Cl_2 \rightleftharpoons WCl_6$ and $WCl_6 + 3H_2 \rightleftharpoons 6HCl + W$ are discussed in connection with the practice of tungsten plating by decomposition of WCl_6. The next two chapters give an outline of the practice and the various applications of tungsten and molybdenum plating. It is interesting to note that the author's experiences with uni- and polycrystalline tungsten wires do not, in many cases, lend support to Tammann's assumption of inter-crystalline impurities as the *only* agents which prevent coalescence of adjacent crystallites. The last chapter contains measurements on the diffusion constant in single crystals and in polycrystalline material.

Apart from some minor errors, there is only one criticism that the reviewer feels inclined to make, viz., the information is largely based on the work of the author and his co-workers and that of Dutch and German investigators. If Dr. van Liempt should decide to publish an English version of his researches which have appeared in Dutch and German periodicals, it might be advisable to include references to non-European literature. Of the American authors, Langmuir is the only one who is frequently quoted.—H. S. van Klooster (7a)-B-

Tungsten Bows to the Plating Bath. COLIN G. FINK. *Scientific American*, Vol. 145, Oct. 1931, page 231.

The author is head of the division of electro-chemistry at Columbia University. The first attempts to plate W were made by a German chemist, Zettnow in 1867. He used a bath of molten sodium tungsten and succeeded in obtaining a tungsten oxide by electrolysis, but failed to make pure W. Recent developments consist of passing an electric current through an aqueous solution of sodium tungstate. Deposits of metallic tungsten are successfully produced on a variety of metals, including brass, Cu and Fe; also C. The W deposit is smooth, hard and coherent, having a high luster. The sodium carbonate solution, to which tungstic acid has been added, is in most respects easily made up; it is neither poisonous nor corrosive. The salts can be readily obtained on the market and in a pure condition; the W deposit produced is clean and bright; no addition agent, such as glue is necessary. W is considered, to-day, one of the key metals of civilization. On the basis of annual tonnages the world, output is less than one-third that of Ni, and only about ten-fold that of Au. However, due to such fundamentally economic products as W alloy steel and W filament lamps, W to-day occupies fifth place among the first ten essential metals of modern civilization. The outstanding valuable chemical and physical properties of the metal and its alloys and compounds, such as, for example, the metal's resistance to severe corrosive agents, including hydrochloric acid and the extreme hardness, second only to the diamond, that can be brought about by the addition of small percentages of other elements to the W, ensure for the metal, its alloys and compounds a far reaching future development. To be deprived of W would cripple a dozen industries, including the lighting industry, the steel industry and radio. WAT(7a)

High Capacity Nickel Baths. (Hochleistungsnickelbäder.) K. ALTMANSBERGER. *Oberflächentechnik*, Vol. 8, Sept. 1, 1931, page 185.

Quick plating baths work with moving cathodes and a temperature above 50° C. The composition of such a bath of 100 l. is given as follows: 32 kg. nickel sulphate (64 g. Ni in one liter), 5 kg. sodium citrate, 1.5 kg. magnesium sulphate, 1.7 kg. boric acid, 1 kg. ethyl sulphate of sodium, 130 g. citric acid, 100 g. HCl; concentration 21° Bé, pH 5.2–5.8, temperature 45° C., voltage 3.5–4.5 volts, current density 1.5–2.0 amp./dm.², plating time ½ hr. Supervision must extend to checking the pH number, density Bé degrees) and content of Ni. The latter is determined titrimetrically every week and takes only 5 mins. A few suggestions are given for procedure in case complications should arise. Ha(7a)

Correcting Engravings by Projected Electrolyte. WILLIAM E. BAILEY. *Metal Industry*, N. Y., Vol. 29, Aug. 1931, pages 344–345.

By projecting a solution containing 159–200 g./l. $CuSO_4$, $5H_2O$ and 50–100g./l. H_2SO_4 onto an inclined Cu plate and making it either anodic or cathodic, using voltages around 15 and current densities around 800 amps./ft.², Cu can be locally removed and replaced ready for re-engraving. PRK(7a)

INDUSTRIAL USES & APPLICATIONS (9)

Merchant Ships of High Elastic Limit Steel. F. G. MARTIN. *Metal Progress*, Vol. 20, Aug. 1931, pages 65–67.

The author described the application to ship building of high elastic limit steel, produced by air cooling from 850° F. WLC(9)

Laying Rails by Heats. H. H. MORGAN. *Railway Age*, Vol. 90, June 20, 1931, page 1191.

A very brief article discussing the advantages of laying rails of one heat together, instead of using the present system of laying them hundreds of miles apart. A closer survey might be kept of the service record. Physical mechanical properties vary less in one heat than in several heats, thereby insuring better joining and matching. Failures due to faulty heats would not be so widely scattered. Costs would not be reduced in replacements but the number of joints between new and worn rails would be less. The article points out that the railroads in the long run would profit by such a procedure. WAT(9)

Colloidal Platinum and Its Behavior as a Typical Acidoid Sol. S. W. PENNYCUICK. *Journal American Chemical Society*, Vol. 52, Dec. 1930, pages 4621–4635.

Experiments are quoted which show that the whole of the colloid surface appears to be coated with a layer of oxidized platinum. On passing hydrogen the oxide layer is reduced and the acidoid properties disappear. On repassing oxygen or air the acidoid properties are recovered. All the reactions of colloidal platinum are intimately connected with the acidic nature of the surface. MEH(9)

Light Weight Alloys in Aircraft Enignes. E. F. LAKE. *Metal Industry*, N. Y., Vol. 28, Nov. 1930, pages 508–511; *Metal Industry*, London, Vol. 38, Jan. 23, 1931, pages 113–115.

Development of light alloys much tougher than cast Fe and equalling some of the steels in physical properties are being used in aircraft engines, due also to being much lighter than steel. Connecting rods are made of duralumin and when correctly heat treated it is possible to get a tensile strength of 70,000 lbs./in.^{2} and elastic limit of 56,000 lbs. with an elongation of 15% in 2 in. and Brinell hardness of 120. Crankshafts are from a medium Cr-Ni steel. Cylinder heads are of Y-alloy produced by adding 2.00% of Ni and 1.50% Mg to Al alloy containing 4.00% of Cu. Mg alloys are 38% lighter than Y-alloys and show indications of being a competitor. VSP(9)

Thermal Efficiencies of Aluminum Saucepans. C. LANDRETH & R. O. HUTCHINSON. *Journal Home Economics*, Vol. 21, Aug. 1929, pages 599–604; *Journal Chemical Education*, Vol. 7, Jan. 1930, page 194.

Relative efficiencies of light and heavy aluminum ware were determined by: (1) rate of heating; (2) retention of heat; (3) proportion of water evaporated during cooking process: (4) durability; (5) cost. As results of this study it may be assumed that: (1) the thermal efficiencies of light and heavy cooking utensils are the same; (2) the loss of water by evaporation is a function of the fit of the lid and not of the thickness of the wall; (3) the difference in cost between well-constructed light and heavy aluminum ware can only be justified on the grounds of greater durability. (9)

Some Added Uses for Lead Pipe. C. L. MANTELL. *Heating, Piping & Air Conditioning*, Vol. 3, July 1931, page 635.

A very brief note to indicate a new use for lead pipe. To obviate the necessity of stocking a supply of spare gaskets of odd shapes, a coil of small size medium weight lead pipe may often supply the need. If lack of space prevents such thickness the pipe may be split. Asbestos rope packing inside a piece of lead pipe provides a very serviceable gasket. The difficulties encountered when removing an old gasket are lacking when such a gasket is used. WAT(9)

Modern Materials and Material Problems in the Construction of Chemical Equipment. (Neuzeitliche Werkstoffe und Werkstofffragen des Chemischen Apparatebaues.) KESSNER. *Chemische Fabrik*, Vol. 4, May 27, 1931, pages 233–238; June 3, 1931, pages 250–252; June 17, 1931, pages 266–269.

Contains 12 references. A review of the chemical resistance, mechanical properties, technical workability and welding properties of steel, iron, stainless steel, lead, nickel, Ni alloys, aluminum, heat resistant metals and coatings, parkerizing and enameling processes, hard rubber, synthetic resins and a new material called prodorit. CEM(9)

Light Alloys in Engine Construction. E. F. LAKE. *Aviation Engineering*, Vol. 6, July 1931, pages 15–17.

One of the aircraft engines using light alloys most freely is the American Ensign engine. All the outside parts of this engine are made of light weight alloys, except that part of each cylinder that is rubbed by the piston rings. This is cast iron because nothing has yet been discovered that will glaze over and withstand frictional wear like cast iron. Inside the crankcase, the crankshaft, camshaft and gears are still steel because they get strains and stresses that are beyond the strength resistance of any light weight metals or alloys so far discovered. The cylinder head is made from the Y-alloy produced in England by adding 2% of Ni and $1^1/_4$% of Mg to the aluminum alloy containing 4% of Cu. Its weight is 185 lbs./ft.^{3}, which is about $^2/_5$ of the 450 lbs. that cast iron weighs. It has double the tensile strength of cast iron and is much tougher. A duralumin connecting rod is used on this engine because it is $^1/_3$ of the weight of steel/ft.^{3} Its elastic limit of 55,000 lbs./in.^{2}, however, is but $^1/_3$ that of the best grades of alloy steels and if that were the only factor to consider the sectional area of the dural connecting rod would have to be 3 times as great to produce the total strength and nothing would be gained. But stiffness is a factor that must be considered and to machine chrome-nickel steels down to the thinness and lightness their high elastic limit would warrant, would make them too springy or flexible. To complete the light weight motive of this engine, all parts of its De Palma supercharger were made of the same Y-alloy that is in the cylinder heads described above. WHB(9)

Metal Rotors of Autogiro Hinged for Stability. BIRAN VON LINDEN LANSDOWNE. *Iron Age*, Vol. 128, July 30, 1931, pages 302–303.

Hinging of blades has the important effect of eliminating most of the bending stresses. Blades of rotor are made of elliptical steel tubing. The flexibility of the blades is an important element of autogiro characteristics and is rendered possible only by means of hinging. Hinging also eliminates gyroscopic action of rotor. VSP(9)

Airplanes must be Safe. ROBERT E. JOHNSON. *American Machinist*, Vol. 74, Feb. 26, 1931, pages 345–348.

The Boeing plant at Seattle, Wash., manufactures both commercial and government planes. These are both inspected by factory inspectors and the government planes by government inspectors also. Discusses parts tested and gives some requirements. Table gives chemical and physical requirements of metals used in construction of the airplanes. RHP(9)

Correlating Theory and Practice in Pressure-Vessel Design. NORMAN W. KRASE. *Chemical & Metallurgical Engineering*, Vol. 37, Sept. 1930, pages 540–543.

Reviews principles of design, discusses selection of materials, and outlines methods of fabrication and of testing pressure vessels. MS(9)

Cast vs. Welded Flywheels. ROBERT E. KINKEAD. *American Machinist*, Vol. 74, Apr. 2, 1931, pages 547–548.

Welded steel flywheels are more economical than cast only when the speed or the diameter may be increased. This applies only to the plain disk type of steel wheel. RHP(9)

Piping Reliability of Importance in Power Plant Near Arctic Circle. R. A. HANRIGHT. *Heating, Piping & Air Conditioning*, Vol. 3, Sept. 1931, pages 741–745.

On the west coast of the Hudson Bay, almost within fringe of the Arctic Circle, the first unit of an eight million bushel grain elevator is being constructed for the Department of Railways and Canals, at Fort Churchill, scheduled to be ready for operation Sept. 1, 1931. A power plant will supply the electrical energy to operate motors driving the elevator machinery and the steam for the dryers and heating. The plant contains 3 boilers, two 600 hp. units and one 300 hp. unit all working at 275-lb. pressure, and delivering superheated steam at 650° F. Great care has been exercised in the selection of the equipment especially the piping. The plant will operate 3 months each year. All piping has been carefully installed, particular attention being given to the ease of draining when the plant is not in operation, as winter temperatures of −50° F. are not uncommon. WAT(9)

Electric Steel Rails. (Rails fabriqués au four électrique.) E. HOUBAER. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 385–387.

Raising the C content of rails above 0.55–0.65% is undesirable from the point of view of ductility. This C gives too soft a steel, so that either heat-treatment or the introduction of suitable alloying elements is called for. A homogeneous rail is more desirable and so alloying is the better procedure. To produce such rails and to meet rail specifications one is more certain of getting uniform results from heat to heat by duplexing converter metal in the electric furnace than by using the open-hearth. The compact structure of electric steel makes it better fit for rail use. HWG(9)

The Use of Aluminum in Roofing. (L'impiego dell' alluminio nella copertura di edifici.) H. FROIDERAUX. *Metalli Leggeri*, Vol. 1, May–June 1931, pages 35–40.

Aluminum tile are reported to have been successfully used in the United States, but favorable European experience is lacking. Favorable results have been had with roofing of Al sheet 0.1–0.3 mm. thick, fastened to a wooden support by a bituminous adhesive in the fashion sometimes used for copper sheeting. Special joints are made between sheets. This type does not have great mechanical strength, and has to be laid with care. The most used type is a roofing of sheet 0.6–0.8 or 1.0 mm. thick with grooved joints applied much as is the case with copper or zinc roofing with due regard to requirements as to thermal expansion. The material is 99.2% or, better, 99.5% Al or else an Al Mn alloy sheet. It is claimed that in atmospheres saturated with ammonia and combustion gases, comparative lives have been: Zn, 3 to 4 years; Cu, 6 years; Al, 12 years. The gage of sheet compared is not stated. It is also claimed that Al is the most economical metallic roofing, all things considered. HWG(9)

Development of Steel Construction in the United States of America. (Die Entwicklung des Stahlbaues in Amerika.) O. VON HALEM. *Stahl und Eisen*, Vol. 51, June 1931, pages 734–739.

The artic e reviews the recent development of steel frame construction in the United States. GN(9)

Electrically Welded Construction. (Elektrisch geschweisste Konstruktionen.) H. HINTZ. *Stahl und Eisen*, Vol. 51, Feb. 26, 1931, pages 258–260.

Report 170 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The article deals with the application of electric welding in machine construction, as, for instance, in the case of cranes, dredges, drums, frames, large gears, etc. The saving of weight is the greatest advantage of electric welding. GN(9)

The Welding of Steel Structures. (Die Schweissung im Stahlbau.) A. HILPERT. *Die Bautechnik*, Vol. 9, July 24, 1931, pages 177–180.

Describes the progress in welding of steel structures of the past $1^1/_2$ years, and explains the mechanics of welding and the places where welds are used. MAB(9)

Welding in the Heating Industry. J. F. HUMPHREY. *Welder*, Vol 2, Aug. 1931, pages 19–22.

Description and illustrations of welding of bends, pipes, pipe lines, etc., and of equipment necessary for welding in the field. Ha(9)

Using Steel in Building the Private Residence. THOMAS J. FOSTER. *Iron Age*, Vol. 128, Aug. 6, 1931, pages 370–398.

This article is the first of a series telling what has been done and outlining some of the developments which the future is likely to bring forth. The importance of the use of steel in relation to private residence is in proportion to its ability to make possible an improved construction at a reduced cost. VSP(9)

Wear Allowances and Tolerances on Gages. E. J. BRYANT. *Metal Stampings*, Vol. 3, Oct. 1930, pages 895–896.

Abstract of a paper read before the Society of Automotive Engineers. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 39. MS(9)

Care of the Detachable-Blade, Metal Propeller. FRANK W. CALDWELL. *Aviation*, Vol. 30, June 1931, pages 357–359.

Propellers made of magnesium alloy are beginning to come into use. This material weighs only 6/10 as much as the aluminum alloy and has splendid fatigue properties. It is, however, subject to corrosion if exposed to salt water or salt spray and must be thoroughly protected from contact with them. The following procedure has been found to be fairly satisfactory as a means of protection. The blades are first treated in a neutral magnesium phosphate solution, which results in a coating somewhat similar to the Parkerizing of steel parts. On top of this coating, 2 or 3 coats of Duco, or enamel are applied. The propeller should be wiped off with oil every day, or after each flight. By the use of these precautions, it is possible to take advantage of the light weight of this material even for operations near the sea coast. (9)

The Modern Steel Casting. R. L. COLLIER. *Iron & Steel of Canada*, Vol. 14, Mar. 1931, pages 57–59.

A brief article, calling attention to the advantages possessed by steel castings in engineering practice. OWE(9)

Requirements on the Material and Production of Modern Boiler Design. (Aufforderungen an Werkstoff und Herstellung in neuzeitlichen Dampfkesselbau.) E. BLOCK. *Glückauf*, Vol. 67, Apr. 18, 1931, pages 524–527; Apr. 25, 1931, pages 551–558.

The present trend of using higher temperatures and pressures in steam boilers makes imperative special attention to the mechanical properties of mild steel which is the most important material for the construction of boilers. The author discusses the correct treatment, points out defects which may arise in it due to improper handling and indicates ways and means for their prevention. Guarantee tests on the principal parts of the boiler, shell, fittings and rivets are discussed. The need for careful supervision of the construction is emphasized and illustrated by an example. HEAT TREATMENT (10)

Heat-Treatment of Aircraft Parts. HORACE C. KNERR. *American Machinist*, Vol. 74, Feb. 26, 1931, page 369.

Abstract giving tables taken from a paper in the Proceedings of the American Society for Testing Materials, Vol. 30, Pt. 2, pages 154–170. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 849. VSP(10)

Rolling and Heat-Treatment of Automobile Sheet. (La fabrication et les traitements thermiques de la tole pour l'industrie automobile.) A. T. KATHNER & P. DAMIRON. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 299–311. 15 references, 15 figures.

Traces the evolution of continuous normalizing. Micrographs of grain size suitable for different grades of body and fender stock are shown, with tensile, Rockwell and Erichsen data. See *Metals & Alloys*, Vol. 2, Apr. 1931, page 81. HWG(10)

The Bright Annealing of Copper and Its Alloys. O. S. HASKELL. *Electrical Manufacturing*, Vol. 8, Aug. 1931, pages 41–42.

The first of a series of 2 articles. Cu is crystalline in structure and, normally, the crystals approach a spherical shape. When the metal is cold worked, the crystals or grains are distorted out of their normal shape and the metal tends to become brittle and hard. After wire drawing, for instance, the crystals are no longer in their normal spherical shape, but have been drawn out into long, thin threads more or less cylindrical. When heat is applied to the metal in this condition, new grains are formed which grow in various lengths of time at different temperatures to normal shape. Pure Cu will anneal at a lower temperature than any of its alloys. The greater the amount of the other metals in the alloy, the higher will be the temperature required, within limits. Metal which can be annealed in one minute at a high temperature, can also receive the same anneal in one hour at a much lower temperature. This short résumé of the annealing process makes no attempt at completeness and is given only to show the necessity for wise and careful temperature control. WAT(10)

Quenching, Annealing and Drawing. III. Results. (Trempe, Recuit, Revenue. III. Resultats.) LEON GUILLET. Dunod, Paris, 1930. Paper, $6^1/_2 \times 10$ inches, 490 pages. Price $7.50.

The third volume of this series is not limited to any definite group of readers or subdivision of metallurgy. Conceived to furnish a complete presentation of the changes occuring when metallic bodies are subjected to thermal treatment it gives more than bare figures. Its background is the whole store of knowledge accumulated since the birth of the science and checked by a leader of metallurgical thought. Any given subject becomes here a vivid picture of the problem with all its difficulties, possibilities and complications standing in a sharp relief.

Beginning with pure iron the work passes over carbon and alloy steels, discusses cast and malleable irons and comprehensively covers the non-ferrous field. The latter occupies $^1/_2$ the book, and $^9/_{10}$ of it deals with copper, aluminum and nickel alloys. In its scheme the volume follows a pattern which has become almost classical but with an important difference in that the generally adopted standards of relative values are often revised. If a point appears interesting, and Professor Guillet is eminently qualified to decide this, it is treated with fullness seldom to be found elsewhere, particularly in treatises of encyclopedic character to which the present belongs. There is no hesitation when many pages are required for illuminating the effect of heat treatment on strained metals or, for example, a description is needed of some new system like Fe–Cr–Al, Al-Ti or Cu–Ge. The industrial importance of many alloys is reflected in their minutely detailed treatment. The thorough knowledge of the human side of the question permitted the writer to omit much superfluous data, but with the confidence that the gaps so produced would be filled easily by anyone even slightly conversant with the subject. One can be certain that newness or obscurity of a process by no means will prevent its presence in the pages of this volume, provided it deserves some attention. High temperature annealing of steel castings and modern methods for heat treating of rails serve as good examples. Everything of interest in the literature is recorded bringing the references given to papers published in 1930. It must be noted that treatments involving any chemical changes are not included here.

Among a very large number of data it is difficult to find a single error. Recommendations of eight hour pickling for patented wire, of the use of a blowtorch for heat treating riveting sets or some other similar statements become striking only after crossing the ocean. If there is a point of complaint it would be found in a somewhat individualistic opinion regarding the importance of some subjects. Thirty lines assigned to silicon transformer sheets, the absence of data on annealing high carbon steels, ninety photomicrographs of high speed steel compared with thirty-eight for all other alloy types illustrate this.

The plan of the work and the treatment of the material bear witness to the exhaustive knowledge of its author, much thought and a remarkable facility for clear expression. Only once in a while a jarring note is felt. A quarter of a century is a long period in a rapidly growing science, and one feels that heat treating data as old as that introduced even occasionally in a modern book cannot fail to affect the harmony of the whole.

The highest aim of a good technical book is giving correct information. Then comes the range of the subjects covered and an important place is occupied by the manner in which the data are conveyed to the reader. An author who can meet helpfully an audience ranging from the man spending all his time in heat treating, say, cluster gears, to the college professor dealing daily with the whole gamut of steels and non-ferrous metals is very fortunate in his achievement. These books are rare, they leave a lasting impression on metallurgical literature and they are welcomed unanimously by the profession. Trempe, Recuit, Revenu is one of them.—John D. Gat (10)-B-

Tempering of Quenched Steels. (Contribution a l'étude du revenu des aciers trempés.) P. CHEVENARD & A. PORTEVIN. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 263–282.

Includes discussion, 72 figures and 11 micrographs. Five high C, high Mn or Cr steels were studied in detail, these being chosen to give various proportions of austenite and martensite on quenching. Dilatometric and thermomagnetic tests were made, supplemented by measurements of resistance, of hardness and by metallographic examination. Results are plotted in great detail for various quenching and drawing temperatures. The tempering of austenite comprises 3 reactions, change to cementite plus a lower C austenite, change to cementite plus martensite and change to martensite. That of martensite is a progressive decarburization of the solution of C in α-iron, spread out over a long temperature interval. HWG(10)

Decarburization and Desulphurization of Steel and Pig Iron by Hydrogen. (Die Entkohlung und Entschwefelung von Stahl und Roheisen durch Wasserstoff.) J. CIOCHINA. *Stahl und Eisen*, Vol. 51, Aug. 13, 1931, pages 1024–1026.

A rapid method for the decarburization and desulphurization of white pig iron and steel by means of hydrogen containing 0.3–0.5% O_2 is described. The experiments were carried on at various temperatures. 12 steels with C contents between 0.27 and 0.86% were decarburized for 3 hrs. at 1250° C. The best temperatures of desulphurization are between 1400° and 1450° C. By means of the method described, it was possible to transform white pig iron to gray cast iron and to make Armco-iron from electric steel. GN(10)

Thermomagnetic Investigation of Tempering of Quenched 0.75 Percent Carbon Steel. GEORGE A. ELLINGER. *Bureau of Standards Journal of Research*, Vol. 7, Sept. 1931, pages 441–451; *Research Paper Bereau of Standards* No. 350.

Previous investigators have shown that martensite and retained austenite are present as constituents of quenched carbon steels. A study of the decomposition of these constituents in water quenched 0.75% C steel has been made by means of thermomagnetic analysis. An astatic magnetometer was used to show changes in magnetization of specimens at various temperatures and these magnetization changes have been interpreted in the light of constitutional changes in the steel. Immediately upon the application of heat, an increase in magnetization took place, which is believed to represent stress release, caused by the precipitation of C from the supersaturated solid solution of C in α-iron. The degree of tempering is believed to be dependent upon temperature and time, the first stage being completed at 200° C. in about $6^1/_2$ hours. The precipitated C is believed to combine with iron in the range between 200° and 300° C. to form iron carbide. This combination is progressive with time, being completed at 300° C. in about one hour. From 300° to 700° C. no further magnetic changes were noted upon holding at constant temperatures, consequently no further constitutional changes were believed to take place in this range, but the carbide apparently coagulated to form larger and larger particles. An increase in magnetization at about 235° C. was believed to indicate the decomposition of austenite, the decomposition being completed in about 45 minutes at that temperature. WAT(10)

Hardening (10a)

The Quenching and Aging of Low-Carbon Steels. (Trempe et vieillissement des aciers extra-doux.) A. BATES. *Comptes Rendus*, Vol. 193, July 6, 1931, pages 35–38.

In an article accompanied by 3 diagrams, the author discusses the results of a series of experiments carried out on basic open-hearth steel containing 0.026% C. The characteristics of the curves shown in 2 of the diagrams are explained by the author in terms of the variable solid solubility of cementite in any α-Fe. The author has also experimented on a series of bars of steel containing different amounts of C, which were prepared by decarburization in H at 925° C. He found that steel containing less than 0.012% C could not be hardened by aging and, on the basis of this observation, suggests that this percentage of C represents the limit of solubility of cementite in α-Fe at room temperature. OWE(10a)

The Mechanism of Steel Hardening. (Der Mechanismus der Stahlhärtung.) G. KURDYUMOV & G. SACHS. *Naturwissenschaften*, Vol. 18, May 30, 1930, page 534.

See *Metals & Alloys*, Vol. 2, Sept. 1931, page 177. WHB(10a)

Annealing (10b)

Continuous Electric Furnace for Annealing Metallic Strips. (Four electrique continu pour recuit des bandes metalliques.) OTTO JUNKER. *Journal du Four Electrique*, Vol. 40, July 1931, pages 278–280.

In annealing sheets or strips until now it was necessary either to pile the former or to coil the latter before introducing them into annealing furnace. This resulted in a pronounced temperature lag between the inside and outside layers of the metal. By unrolling the strip and passing it through the heated zone of a furnace it is possible to heat it throughout almost instantaneously. An electric furnace was designed on this principle with the capacity of 6 tons of 0.2 mm. × 30 mm. brass strip per 24 hrs. The furnace proper is 500 mm. wide permitting the simultaneous passage of 4 strips. It is kept at 800° and permits excellent regulation of the annealing treatment by changing the speed of the strip. At the present these furnaces are used as a part of units including, besides strip handling equipment, cooling, pickling, brushing and drying devices. The furnace is well insulated and the current consumption corresponds to an effiiciency of 85–92% calculated on the theoretical requirements for heating the strip. Structural details are given. JDG(10b)

Applications of the Electric Furnace for Non-Ferrous Metals, with Special Reference to the Bright Annealing Process. H. C. KLONINGER, G. KELLER & H. MEUCHE. *Institute of Metals, Advance Copy* No. 575, Sept. 1931, 18 pages.

Discusses the principally used bright-annealing processes, which include the Kenworthy, Heddernheim, Brown Boveri and Grünewald processes. It is shown that considerable improvement in bright annealing processes have been made in the last few years. The operation of the Grünewald process is described in detail. JLG(10b)

The Annealing of Foundry Hooks and Chains. WILFRID DUNKERLEY. *Foundry Trade Journal*, Vol. 43, Nov. 20, 1930, pages 355–356.

Foundry hooks and chains are heated up to 700° C. for 2 or 3 hrs., then allowed to cool in the furnace. Describes tests conducted. Experiments show that temperature of 950° C. should be used in preference to that of 700° C. if maximum strength and minimum grain size is required. Low temperature annealing effected little or no improvement in the strained material. Tabulates results. VSP(10b)

Composition, Temperature, Time and Control Govern Short Anneal. EDWIN BREMER. *Foundry*, Vol. 59, Aug. 15, 1931, pages 32–34.

The first of 2 articles on shortening of malleable cast Fe annealing cycles. There has been a constant search for methods whereby the annealing period could be reduced. Cites various authorities on the subject. According to Archer and White, as the temperature of anneal increases, the time necessary decreases and, at about 1500° F., the time required is 10 hours. Includes a table giving chemical and physical properties of annealed bars and several graphs. VSP(10b)

The Chemical Effect of Gaseous Atmospheres in the Bright Annealing of Metals. R. J. COWAN. *Metal Industry*, N. Y., Vol. 29, Aug. 1931, pages 333–335.

Above 800° F., brass liberates gas, one being carbon dioxide which causes tarnishing. Carbon monoxide decomposes to C and carbon dioxide. Pure H bright anneals at 1250° F., but aids the volatilization of Zn. Hydrocarbons must be broken down to H and C at 1250° F. in the presence of Fe catalyst to satisfactorily bright anneal. Decomposed ammonia must also be used at 1250° F. By adding methanol to dried flue gases, bright annealing of brass is possible at any annealing temperatures. PRK(10b)

Case Hardening & Nitrogen Hardening (10c)

The Influence of High-Frequency Electrical Oscillations on the Properties of Metals and Alloys. JULIUS GRANT. *Metal Industry*, London, Vol. 38, June 12, 1931, page 593.

The work of Mahoux in France is mentioned. Electromagnetic oscillations increase the penetration of ammonia in nitriding processes, and increase the diffusion of chromium and of carbon into iron. PRK(10c)

Correlation of the Crystal Structure and Hardness of Nitride Cases. OSCAR E. HARDER & GEORGE B. TODD. *American Society for Steel Treating, Preprint* No. 6, 1931, 22 pages.

Paper to be presented before the Boston Convention of the Society, Sept. 1931. 13 references to the literature are cited. Ingot iron, S.A.E. 1025, Cr-Al and two Cr-Al-Mo nitriding steels were nitrided and a study made of their crystal structure by X-ray defraction methods, their Vickers hardness and microstructures. Hexagonal close packed lattice was found in all samples and was accompanied by face centered cubic in all except ingot iron. Transition from surface inward is first to face centered cubic then to face centered with the α-lattice and at low depths, 0.003 to 0.004 inch, the α lattice only is found. Hexagonal close packed lattice is associated with surface brittleness. Cases without it are not brittle. Cases showing only α lattice have full hardness. WLC(10c)

The Influence of High-frequency Vibrations upon the Heat-Treatment of Materials. D. R. LEWIS. *Metallurgia*, Vol. 4, Aug. 1931, pages 126A, 126B.

A review of the work reported in *Le Genie Civil*, in which it was shown that the nitriding process could be accelerated by applying high-frequency vibrations during nitriding. With such vibrations steels can be nitrided that cannot be otherwise. Application is being made of the process in England. JLG(10c)

Case Hardening with Ammonia Gas. V. O. HOMERBERG & J. P. WALSTED. *Transactions American Society Mechanical Engineers*, Vol. 53, Jan.-Apr. 1931, *Machine Shop Practice*, pages 1–6.

The process of "nitriding" is explained, that is a case hardening under the influence of the N in ammonia gas. Steels containing varying amounts of C together with 1–1.25% Al, 1.5% Cr and 0.2% Mo were found to be especially susceptible to this treatment. The material is called Nitralloy. All parts should be heat treated before nitriding in order to obtain desirable physical properties of the core and to insure proper grain refinement because the original grain size of the material is not reduced during the nitriding operation. The depth of the hardened case increases with nitriding temperature, from 900 to 1300° F., but the hardness decreases. It is, however, possible to nitride, first at a high temperature to obtain a considerable depth and then at a lower temperature to obtain the desired surface hardness. The presence of a decarburized layer before nitriding produces a brittle case; this layer should, therefore, be removed first. Ni plating and a coating of Sn will protect parts against nitriding. Nitrided articles offer marked resistance to atmospheric, water and salt water corrosion and show excellent wearing properties, even without lubrication, against certain other alloys, notably against Nitralloy, itself and a nickel bronze. 7 references. Ha(10c)

Development of Continuous Gas Carburizing. R. J. COWAN. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 439, Sept. 1931, 17 pages.

The theoretical aspects of carburizing are discussed. It was found that if a layer of C was deposited on the parts to be carburized, CO_2 will react with the deposited C to carburize the steel. A sufficient quantity of CH_4 will prevent the CO_2 from decarburizing. A continuous gas carburizing process was developed in which the gas and the parts travelled in the same direction. The gas consists of a mixture of natural gas, propane, butane or acetylene with flue gas. The furnace may be considered as divided into 3 zones. In the first or low temperature zone, the hydrocarbons are cracked and deposit C on the steel. Regulation is such that only part of the gas is cracked. The walls are constructed of a special alloy that will not cause C precipitation. In the second or full temperature zone CO_2 (from the flue gas) reacts with the deposited C to carburize the steel. Rapid carburization occurs in this zone and leaves a too sharply defined case. In the third or diffusion zone, the C in the case diffuses into the core. The atmosphere in this zone is of little importance provided it contains sufficient CH_4 to prevent decarburization by the CO_2. Uniform results were obtained and the character and depth of the case could be easily regulated. Operation is faster than with box carburization. Contains 12 references. JLG(10c)

Development of a Continuous Nitriding Furnace. R. J. COWAN. *Fuels & Furnaces*, Vol. 8, Nov. 1930, pages 1517–1520, 1552.

Condensed from *Metal Progress*, Vol. 18, Oct. 1930, pages 93–98. See *Metals & Alloys*, Vol. 2, July 1931, page 132. MS(10c)

Recent Investigations on the Case Hardening of Locomotive Slide Bars. (Neue Untersuchungen über die Einsatzhärtung von Lokomotivgleitbahnen.) HELLMUT CRAMER. *Maschinenbau*, Vol. 10, June 18, 1931, pages 419–424.

A short preliminary discussion is followed by a description of the tests which were carried out at the Reichsbahn-Ausbesserungswerk Sebaldsbrück on case hardening of locomotive slide bars. Both solid and liquid cementation agents were used. A comparison of the value of each is given. 12 photomicrographs. MAB(10c)

The Surface Hardening by Nitrogen of Special Aluminium-Chromium-Molybdenum Steels on a Production Basis. W. H. CUNNINGHAM & J. S. ASHBURY. *Iron & Steel Institute, Advance Copy* No. 7, Sept. 1931, 14 pages.

Describes a commercial nitriding method. Protection against nitriding can be produced by coating with solder or a mixture of Al powder in water glass. Growth of the parts amounts to 0.001 to 0.006 in., and is almost independent of section. Distortion occurs only in rare instances. It can occur, however, when thin parts are nitrided only on one side. The Firth hardometer is recommended for determining the hardness of the case. The decarburized surface must be completely removed from surfaces that are to be nitrided. The nitriding steels usually contain from 0.20 to 0.55% C, depending on the properties required in the core. A nitriding temperature between 500° and 510° C. is recommended. JLG(10c)

Quenching (10d)

New Process of Quenching Steel. (Nouveau procédé de trempe de l'acier.) N. F. BOLKHOVITINOF. *Viestnik Metallopromychl*, Vol. 10, June 1930, pages 88–90; *Chimie et Industrie*, Vol. 25, Feb. 1931, pages 352–353.

Bolkhovitinof experimented with Lewis' process, which consists in heating the steel above the critical temperature and then quenching in a bath of molten salt or of oil heated to 230°. When treated in this way, the steel is at first soft; it consists of austenite, and becomes hard only about 5 min. after having reached ordinary temperature. It then expands, becomes magnetic and is transformed into martensite. Owing to this slow change in structure, all the transformations produced by the variations in volume have time to take place, which completely eliminates the usual defects of the ordinary quenching process, giving great hardness and homogeneity. But from a practical standpoint, the greatest advantage of the method lies in the fact that pieces quenched in this way can undergo all the requisite deformations and flexions in 1–2 min. after quenching. WHB(10d)

Oils Used in Heat Treating Plants. (Beitrag zur Frage der in Wärmebehandlungsbetrieben zu verwendenden Oele.) K. KREKELER & F. RAPATZ. *Archiv für Eisenhüttenwesen*, Vol. 5, Sept. 1931, pages 173–176.

The investigation shows that there are no essential differences between the various quenching oils when first in use. A longer use, however, brings about remarkable differences, which are indicated by the variable resistivity against decomposition and a variable capacity for adhering to the heat treated steel. Vegetable oil is not superior to mineral oils; there are even indications that mineral oils are superior. Oils must be especially resistant against decomposition at high temperatures. The requirements of tempering oils are given. GN(10d)

JOINING OF METALS & ALLOYS (11)

Welding and Soldering in Repairing of Machine Parts. (Schweissen und Löten bei der Reparatur von Maschinenteilen.) W. ANDERS. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 209–211.

Several examples which show the 2 kinds of parts to be joined together are illustrated. In general, parts from 4 to 15 mm. in thickness can be welded economically. For thicknesses up to 150 mm., it might, sometimes, be more advantageous to apply solder in the crevices and between parts. The preparation of the parts in using either method must be given close attention. Ha(11)

Jointing Stainless Steel Sheets by Soft Soldering and Brazing. A. EYLES. *Sheet Metal Worker*, Vol. 22, July 24, 1931, pages 440–442.

A detailed discussion of the methods, materials and procedure control required for desirable results. Compositions of soft solders and fluxes and precautions to be observed for stainless steels are described. Ha(11)

Welding & Cutting (11c)

Past and Future Growth of the Welding Industry. C. A. ADAMS. *Welding*, Vol. 2, Sept. 1931, pages 626–627, 629.

The 2 major factors contributing to the growth of the welding industry in the past 5 years are: The injection of scientific methods into the industry, accompanied by the interest of a group of highly trained technical men; and an appreciation of the superior product and the large material and labor saving made possible by welded construction. The trend of the welding industry during the next 5 years will probably be along the following lines: greater recognition by capital, management and labor; more extensive fundamental research; the further use and development of non-destructive tests for welds; wider application to all metal industries, of the non-ferrous metals and alloys, and to complicated production problems. TEJ(11c)

How to Weld the Chrome-Nickel Steels. Part 1. S. CRAIG ALEXANDER. *Welding*, Vol. 2, Aug. 1931, pages 514–517.

Structural characteristics and physical properties of "18 and 8" Cr-Ni steel are given, particularly those which have a bearing on its welding characteristics and physical properties of the welded material. Heating KA2 to 1000–1400° F. causes carbide precipitation which decreases resistance to corrosion. KA2-S, which has a low C content (less than 0.07%), is recommended for welded structures which cannot be heat-treated as a whole and where carbide precipitation is a disturbing factor. TEJ(11c)

Gas Fusion-Welding in Steel Structures. (Die Gasschmelzschweissung im Stahlbau.) K. BERTHOLD & H. KNORTH. *Die Schmelzschweissung*, Vol. 10, June 1931, pages 135–139.

Very exhaustive tests with gas-welded steel structures have shown that this method is absolutely safe and advantageous if the designer and the welder take the particular characteristics of this process into account. Methods for testing large girders, trusses, etc., are described and several examples of structures are illustrated. It is recommended that only symmetric profiles be used for construction. Ha(11c)

Influence of Gas Fusion-Welding on the Bending-Vibration Strength of Chrome-Molybdenum Steel Pipes. (Einfluss der Gasschmelzschweissung auf die Biegungsschwingungsfestigkeit von Chrom-Molybdän-Stahlrohren.) H. BIESSNER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, July 25, 1931, pages 954–956.

The exacting requirements of the vehicle and airplane industry have led to the development of a steel with 0.3% C, 0.75–1.0% Cr, 0.2–0.3% Mo. Tests to determine the bending vibration strength of welded and non-welded pipes are described. The non-welded pipes gave 24–26 kg./mm.^{2}; the properly welded tubes, 15–16 kg./mm.^{2} Dynamically strained pipes up to 2 mm. wall thickness welded with a low-carbon unalloyed welding pencil; pipes above 2 mm. with a pencil containing Cr-Mo addition. The welding flame must be neutral. The welding seam should be V-shaped with an angle of 80°. The width of the seam is of great influence on the vibration strength; for pipes of 1.5 mm. wall, 8 mm. wide; for 3 mm. wall, 13 mm. wide. Ha(11c)

Possibilities of Resistance Welding. MALCOLM CLARK. *Welding*, Vol. 2, Aug. 1931, pages 531–532, 538.

Abstract of paper presented Jan. 23, 1931, before the Youngstown, Ohio Section of the American Society of Mechanical Engineers. The author discusses method of calculating transformer capacity and the fundamentals of butt, spot and projection welding. Four examples in calculating transformer capacity are given. Spot welding of non-ferrous alloys requires much greater transformer capacity than welding of steel. TEJ(11c)

Simplified Plant Design with Welded Pressure Equipment. J. N. COMPTON. *Chemical & Metallurgical Engineering*, Vol. 37, Sept. 1930, pages 562–564.

Discusses application of welding to construction of chemical equipment. States that tightness, simplicity of design, and ease of erection and changes in the field are inherent in welded equipment. MS(11c)

The Application of Welding to Steel Construction in Germany. OTTO BONDY. *Engineering*, Vol. 131, Mar. 6, 1931, pages 322–323.

Mentions briefly progress made in recent years in using welding in steel construction. With its increasing use in Germany, official regulations covering its use were issued by the Prussian Minister of Public Safety. The following table compares these rules with those of the American Welding Society:

Country		Permissible Unit Stresses lb./in.^{2} Tension	Compression	Bending	Shear
Germany	Base Stresses	10,300	12,800	as for tension and compression	8,600
	Base Stresses + 1/3	13,800	17,200		11,500
United States		13,000	15,000		11,300

German regulations are for open-hearth steel St. 37, the breaking load of which is 23.6 to 28.8 tons/in.^{2} Balance of article deals with regulations as to the methods of welding. LFM(11c)

Aeroplane Welding in America, Methods Used in the Manufacture of Eaglerock Planes. JOS. C. COYLE. *Welder*, Vol. 3, Sept. 1931, pages 36–40.

Illustrated description of the manufacturing process used by the Eaglerock Aeroplane factory at Colorado Springs, Colo. Ha(11c)

Investigations into Economical Flame Cutting. (Untersuchungen über wirtschaftliches Brennschneiden.) C. ASSMANN. *Forschungsarbeiten auf dem Gebeite des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 6, 1931, pages 49–65.

Tests made with 16 mm. and 30 mm. thick wrought iron plates cut with 99% pure O. See *Metals & Alloys*, Vol. 2, July 1931, page 133. Ha(11c)

Arc Welding Makes Possible Steel Frame House of Practical Design. A. F. DAVIS. *Journal American Welding Society*, Vol. 10, Aug. 1931, pages 10–12.

Details of construction are illustrated and explained. It is believed that this type of design will come into wide use; the cost is practically the same as the traditional wood framing. TEJ(11c)

Repair of a Small Boiler Having Become Useless by Rusting by Means of Autogenous Welding. (Instandsetzung einer durch verrosten unbrauchbar gewordenen Kleinkessels mittels autogener Schweissung.) E. BOTHMER. *Schmelzschweissung*, Vol. 10, July 1931, page 172.
Detailed description of the repair of a 6 atmosphere boiler. Ha(11c)

Electrical Resistance-Butt-Welding Machine with Clamping by Compressed Air. (Elektrische Widerstand- Abschmelz-Schweissmaschine mit Presslufteinspannung.) B. LANGBEIN. *AEG-Mitteilungen*, Vol. 4, July 1931, pages 415–418.
A butt-welding machine is described. It is of a normal type but has been equipped with a clamping device for the pieces to be welded which is operated by compressed air to reduce the time for clamping and unclamping. This device is automatic; the air pressure remains during the whole welding process on the clamps so that the pieces are unable to move accidentally. Ha(11c)

Repair Welding on Steam Boilers. (Reparaturschweissungen an Dampfkesseln.) JOH. KRAFFT. *Schmelzschweissung*, Vol. 10, July 1931, pages 167–170.
First, the author discusses the rules and regulations for welding on boilers. This work must be entrusted only to reliable and responsible companies. The kind of boiler defects, corrosion, cracks or dents determines the manner of repair. Several examples and photographs illustrate repairs by welding. Ha(11c)

Welded Magirus Fire Ladder. (Geschweisste Magirus-Feuerwehrstahlleiter.) L. KUCHEL. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, July 18, 1931, pages 940–942.
A fire ladder of 38.4 m. total length in 5 parts is welded together from light steel profiles. The saving in weight, as compared with a wooden ladder, amounted to about 17% or 180 kg. The mechanical construction and test results are given. Ha(11c)

Physical Characteristics of Arc Welded Joints in Pipe Lines. J. F. LINCOLN. *American Gas Journal*, Vol. 134, Aug. 1931, pages 31–32.
The author discusses the reduction of construction and maintenance costs by use of modern welding methods in the fabrication of gas pipe lines. A major factor causing variations in tensile strength is the C content of the pipe metal. It should be kept down to 0.25–0.35% or 0.30–0.40%. The covered electrode arc process using "Fleetweld" gives very good welds. It prevents the formation of undesirable welds by eliminating oxides and nitrides which cause porosity, weaken and embrittle the weld. MAB(11c)

Welding Improves Design of Presses. J. F. LINCOLN. *Welding*, Vol. 1, Nov. 1930, pages 929–931.
The construction of frames of inclinable presses of welded parts provides a better distribution of metal, saving in weight and imparts a pleasing appearance. Ha(11c)

Arc Welding in Europe. E. DACRE LACY. *American Machinist*, Vol. 74, Mar. 19, 1931, pages 463–466; Mar. 26, 1931, pages 505–507.
Ship welding has been retarded by lack of skilled welders, opposition of trade unions, inability to purchase proper materials. Most of these are being removed now. Several welded ships have been built and have shown the value of welded construction. New and lighter steels have been introduced. "Ducol" steel 0.25% C, 1.5% Mn, tensile strength 40 tons compared with 30 tons for ordinary ship plate. Welded joints compared with 30 tons for ordinary ship plate. Welded joints of "Ducol" have tensile strength 40.4 tons/in.^{2}, fracture clear of weld, extension 17% in 8 in. Analysis of weld C, 0.215%; Si, 0.03%; Mn, 1.80%; S, 0.027%; P, 0.035%. Structural welding has been retarded by legislation but welded buildings have been erected in the last few years. Greater progress has been made in welding for railways. A welded carriage frame is in use on the Belgian State Railways, and welding is used extensively for repair work. RHP(11c)

The Measurement of Welded Seams. (Das Messen von Schweissnähten.) E. KALISCH. *Schmelzschweissung*, Vol. 10, July 1931, pages 181–183.
As all values of strength of welded seams are given in lbs./in.^{2} or kg./mm.^{2}, the exact measurement of the dimensions of the weld is of importance. A few special gages and methods of using them are described and illustrated. Their object is to obtain as correct a value as possible. Ha(11c)

Contribution to the Knowledge of the Temperature of the Oxy-Acetylene Flame and the Quality of the Weld in Their Dependence on the Water Vapor Contents in the Acetylene. (Beiträge zur Kenntnis der Temperatur der Azetylen-Sauerstoff-Flamme und der Güte der Schweissung in ihrer Abhängigkeit vom Wasserdampfgehalt im Azetylen.) H. JOOS. *Autogene Metallbearbeitung*, Vol. 24, Aug. 15, 1931, pages 241–252; Sept. 1, 1931, pages 259–267.
In an extremely exhaustive investigation, the temperature of the acetylene flame, the behavior of the oxy-acetylene flame and its temperature were determined for various contents of water vapor. The temperature of the flame was always assumed to be approximately 3000° C. The temperature is measured optically by means of the reversal of the spectral lines; it varied between 3250° and 2900° according to the amount of the water vapor (from 0 to 39.5%) and the height above the inner cone at which it was measured. The results were checked by 2 computing chemical methods. As a general result, it can be stated that water vapor up to about 7% as it occurs in acetylene has no harmful influence for practical welding either on the temperature of the flame or on the quality of the weld. Ha(11c)

Welded High-Pressure Tanks and Fittings; Applications of Experience in Steam Boiler Construction. (Geschweisste Hochdruckbehälter und Armaturen; Verwertung der Erfahrungen im Dampfkesselbau.) K. JURCZYK. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, June 27, 1931, pages 859–864.
This is a report on welding of tanks and fittings and of the difficulties experienced with it. Experience with boilers is of great help in making tests to find means for overcoming these difficulties. A great number of illustrations show the procedure in welding which may be most advantageously applied. Suggestions are made for guaranty tests. Ha(11c)

Increase of Output by Multiple Flame Welding Torches. (Leistungssteigerung durch Mehrflammenschweissbrenner.) E. KALISCH. *Die Schmelzschweissung*, Vol. 10, June 1931, pages 149–156.
An increase in the output of welds with simultaneous improvement of quality can be obtained by preheating the piece, by selecting a larger flame, by welding from both sides, by using right hand welding, or by the use of a multiple flame torch. The pipe welding machine with multiple flame torch increases production from 3 to 6 times. Different types of torch for different kinds of work are described and the saving of time as compared with the usual single flame torch is noted. A welding machine for welding of sheets from both sides is described. Ha(11c)

Switching and Welding Oscillograms of Rosenberg-Crossfield Dynamos with Regulating Poles. (Schalt- und Schweissoszillogramme von Rosenberg-Querfelddynamos mit Regelpolen.) F. KNILL. *Elektrotechnische Zeitschrift*, Vol. 52, July 9, 1931, pages 903–907.
The phenomena occurring during welding with metal electrodes, short-circuit and reduction of load of the welding machine are discussed. This discussion is based on oscillograms. The advantages of the Rosenberg-dynamo over other types of machines with regard to the damping of fluctuations are pointed out Ha(11c)

The Future of Welded Ship Construction. J. KJEKSTAD. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 13–16.
Paper presented before the fall meeting of the American Welding Society in Boston, Sept. 1931. Requirements of the design and method of construction of welded floating crafts are: maximum structural inherent and permanent efficiency; economy in designing, fabricating and erection; economy in operation and maintenance. The Truss Weld and the Reverse Channel systems of welded design are illustrated and explained. A welded hull will outsell, outwork and outlive any other type of hull. TEJ(11c)

The Relief of Welding Strains by Annealing. CHAS. H. JENNINGS. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 26–29.
Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Strains set up in welded specimens and residual stresses after annealing at 1000° F., 1100° F. and 1200° F. for various lengths of time, were measured by means of a strain gage. Welding strains and residual stresses can be reduced by annealing at a temperature below the critical. Reduction of welding strains depends on temperature and soaking time. Residual welding stresses can be reduced to a few thousand lbs./in.^{2} 4 references. TEJ(11c)

Use of the Oxy-Acetylene Flame in Making Storage Batteries. (Anwendung der Azetylen-Sauerstoff-Flamme im Akkumulatorenbau.) GUSTAV JONSCHER. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 189–190.
The hydro-oxygen flame which was formerly used for Welding lead is now almost entirely replaced by the oxy-acetylene flame because, with proper adjustment, it offers the same advantages and is cheaper, both in wages and fuel. Ha(11c)

Fabrication of Pipe Specials. OWEN C. JONES. *Journal American Welding Society*, Vol. 10, Aug. 1931, pages 13, 44.
Brief descriptions with illustrations of some special pipe connections fabricated by the oxy-acetylene process. TEJ(11c)

Future Development of Electrodes. T. E. JERABEK. *Welding*, Vol. 2, Sept. 1931, pages 623–625.
A review of the developments in arc welding electrodes during the past 5 years and a forecast for the future. Design of the electrode of to-day requires a knowledge of physical chemistry and metallurgy. Shielded arc electrodes will be further improved to produce welds having better physical properties. Higher welding speeds will be obtained and larger diameter electrodes, operating at higher currents and higher voltages, will be used. TEJ(11c)

Welding Applied to Compressed Air Machinery. H. W. KEEBLE. *Welder*, Vol. 2, Aug. 1931, pages 25–26.
Notes the possible economies for welded parts, especially for portable equipment. Ha(11c)

The Field of Resistance Welding. P. M. HALL. *Welding*, Vol. 2, Sept. 1931, pages 607–608, 610.
Advancements in the art of resistance welding during the past 5 years have been in the form of improved machines to fit the job, and more nearly foolproof methods of operation. The establishment of welding research laboratories; a change from the sliding patent design to a swinging grease-sealed bearing design; a method for removing the flash; and improved seam-welding machines, are forecast for the future. TEJ(11c)

The Metallurgy of Welding of Steel with Particular Consideration of Steam Boiler Construction. (Zur Metallurgie der Schweissung von Stahl, mit besonderer Berücksichtung des Dampfkesselbaus.) A. FREY. *Krupp'sche Monatshefte*, Vol. 12, Aug.-Sept. 1931, pages 201–214.
The first thing which must be considered in the manufacture of welded steam-boilers is the necessity of selecting material that is suitable, from the viewpoint of weldability, endurance strength, aging and corrosion resistance. The electric resistance welding process is, metallurgically, the most favorable pressure welding method for small sections. Water gas welding has been proved successful. The different fusion welding methods are not yet sufficiently developed. It is shown that even when alloyed electrodes are of a composition very different from that of the main material, they produce seams of high strength and toughness. This method promises to be of particular advantage in the future for boiler design. A standardization of testing methods, especially, of dynamic testing, is advocated. 18 bibliographical references are given. Ha(11c)

Welding Manganese Steel. JOHN HOWE HALL. *Electric Traction*, Vol. 27, Aug. 1931, pages 400–402.
Mn-steel as made and used for special track work and containing about 1.25% C and 11–14% Mn has always been a difficult material to weld successfully. On account of its high C content, Mn steel in its cast state contains a large amount of free carbide or cementite, which makes it weak and brittle until it is heat treated by quenching in water from a high temperature. This treatment makes the steel strong and tough, due to the complete solution of the carbide. The quenched steel very readily liberates its carbide again on reheating to comparatively low temperatures. The Taylor-Wharton Iron and Steel Company has recently developed and patented (U. S. Patent 1,732,202) a special type of Mn steel which has been christened Timang, which contains the usual proportion of Mn, a lower content of C, and about 3% Ni. This steel does not normally contain free carbide, and does not require quenching in water to render it tough, in fact, a plain normalizing treatment is all that is generally applied to it. When used as a welding rod for making welds in Mn steel castings, this special steel appears to affect the zone of the weld in two ways. In the first place, it dilutes the C of the Mn steel close to the weld so that there is less tendency to the liberation of carbide than when regular Mn steel is used as a welding rod, and in the second place, it causes the Mn steel close to the weld to absorb a certain amount of Ni. The low C and the Ni content of the weld zone so reduce the carbide separation and promote the air toughening property that welds made with this rod are tougher in the condition as welded than even reheat-treated welds made with Mn steel rod. WAT(11c)

Cause and Prevention of Heat Cracks in Aircraft Welding. H. S. GEORGE. *Welding*, Vol. 2, Aug. 1931, pages 524–529.
See *Metals & Alloys*, Vol. 2, Sept. 1931, page 178. TEJ(11c)

Welding-Technical Ramblings. (Schweisstechnische Streifzüge.) HANS A. HORN. *Die Schmelzschweissung*, Vol. 10, July 1931, pages 173–179.
A short report on hot-tearing tests made in the experimental and training shops at Berlin on autogenously and electrically welded rods is given. The tensile and elongation values are cited; the results are better for the gas welding method. Mistakes made in the preparation of boiler repair are also discussed and illustrated by photomicrographs. Several good ways are recommended. Ha(11c)

Welding of Copper-Nickel Alloys. (Die Schweissung von Kupfer-Nickel-Legierungen.) HANS A. HORN. *Apparatebau*, Vol. 43, May 15, 1931, pages 112–115.
See *Metals & Alloys*, Vol. 2, Sept. 1931, page 181. (11c)

Critical Review of Welded Pressure Tanks. (Kritische Betrachtung von Druckgefässen in geschweisster Ausführung.) H. HAENDLY. *Schmelzschweissung*, Vol. 10, July 1931, page 171.
Using a pressure tank for 15 atmospheres at 300° C. and 500 mm. inner diameter as example, the calculation is explained with the view of obtaining the lowest factory cost. Ha(11c)

Experiments on the Weldability of Silicon Steel. (Versuche zur Ermittlung der Schweissbarkeit des Siliziumstahls.) H. GRAHL. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 593–599.

Report 173 of the Committee on Materials of the Verein deutscher Eisenhüttenleute. Welding tests under pressure were carried on on structural steels containing up to 1.35% Si. Up to this content, no unfavorable effect on the weldability was observed. The increase of tensile strength through Si is lost in welding due to the oxidation which is favored by the element. The most suitable welding temperature of silicon structural steels is 1435° C. Welded joints had a tensile strength of about 97% of the silicon steel itself. The notch toughness of those joints shows the same characteristic temperature dependence as the non-welded material, the critical temperature range, however, i. e., the transition from high to low values of notch toughness, is shifted to higher temperatures. Best results in welding silicon steels under pressure will be obtained when the joints are heated to temperature as rapidly as possible and the presence of O is avoided as much as possible. GN(11c)

Tests on Weld Metal. P. T. HOLLIGAN. *Welder*, Vol. 3, Sept. 1931, pages 8–20.

A series of tests with 3 types of electrodes ("Cresta," "Medex" and "Ducol") have recently been carried out by the Welding Research Department of the Synthetic Ammonia & Nitrates, Ltd., in England. From them, the following conclusions can be drawn: Medex and Cresta deposit metal which gives a strength comparable to that of ordinary mild steel. Their ductility is about $^2/_3$ that of the best mild steel. The Ducol electrode deposits metal of much higher tensile strength than either Medex or Cresta, but the ductility is slightly less. Under bend tests, Medex metal gave the best results; Cresta was slightly inferior; Ducol was inferior to both the others. Ducol deposits an alloy steel weld containing Mn and Ni. The effects of heating and cooling are therefore, greater on this metal than on ordinary C steel. Most remarkable was the low C content shown in the analyses of the deposited metal which is responsible for the high tensile strengths. An analysis showed in all cases a Ni content of 0.06%. The fatigue tests gave almost as good results as solid homogeneous mild steel. All tests are described in detail and illustrated in micrographs and tables. Ha(11c)

Direct Current, Single Phase or Three Phase Arc Welding? (Gleichstrom-, Einphasenstrom- oder Drehstrom-Lichtbogenschweissung?) J. C. FRITZ. *Elektrotechnische Zeitschrift*, Vol. 52, July 16, 1931, pages 932–934.

The advantages and disadvantages of the 3 methods are weighed against one another. Each of the 3 processes has a special field; but, in general, it is true that in Germany the single-phase arc has gained a foremost position. In this method, as with direct current, an electrode with coating is used preferably. Three-phase welding is seldom used. The constructions and performance of d. c. generators and welding transformers are discussed and some special equipment is described. Automatic welding has been restricted largely to d. c. welding. 6 references. Ha(11c)

Welding of Structural Steel. J. E. FERGUSON. *Journal American Welding Society*, Vol. 10, July 1931, pages 39–43.

Strength of welded joints is comparable to strength of riveted joints. Design of welded members is entirely different from design of riveted members. Illustrations of welded joints are shown and shop and field welding described. The author cites advantages of arc welding over riveting in structural steel fabrication and erection. The proper fabrication of welded steel includes: (1) The use of correct sections. (2) Logical designs for this particular use. (3) Suitable details for welding. (4) Right kind of plant layout. (5) Right equipment, particularly welding machines, grids, jigs and handling equipment. (6) Proper kind of organization, suitable training of welders. (7) Proper inspection. TEJ(11c)

Welding of Cast Iron Pipe. T. W. GREENE. *Journal American Welding Society*, Vol. 10, July 1931, pages 30–33.

Paper presented at joint meeting of American Welding Society, American Society of Civil Engineers, American Water Works Association on June 9, 1931. Laboratory and field tests show advantages of bronze welded cast iron pipe over other methods of joining. Strength of joint, resistance to corrosion and cost are considered. Welding rod used is of the 60% Cu and 40% Zn type. TEJ(11c)

Electric Welding. Annual Report of the Committee on Electric Welding. P. P. ALEXANDER, *et al.* *Electrical Engineering*, Vol. 50, Section II, July, 1931, pages 557–560.

The report consists of two sections—the first dealing with organization and policies, and the second with the progress of the art. Resistance welding, structural steel welding, shipbuilding, automatic machines, alloy electrodes and special arc torches are discussed, and the design of electric arc welding generators, testing of welds and fourteen suggestions given for further research on the phenomenon of the electric arc. WHB(11c)

Welding of Tubes in the Construction of Airplanes. (Ueber die Schweissung von Rohren im Flugzeugbau.) A. KOPPENHOEFFER. *Autogene Metallbearbeitung*, Vol. 23, May 1, 1930, pages 134–137.

The experiences of the Heinkel Flugzeugwerke A.-G. show that acetylene welding of tubes for airplane construction offer great advantages over all other welding methods. Among the advantages noted are flexibility of kind of joints, great liberty in shaping the members, speed of manufacture and, with experienced personnel, neatness of work. Three kinds of material which may be used depending on the purpose are discussed in detail. It is important, in producing a perfect weld, that the sections which are welded together be not too different, since cracks may easily occur near the seam. It goes without question that only most experienced welders are to be entrusted with such responsible work. Ha(11c)

The New Welding Laboratory of the Technical University Karlsruhe. (Das neue Schweisslaboratorium der Technischen Hochschule Karlsruhe.) A. KESSNER. *Die Schmelzschweissung*, Vol. 9, May 1930, page 112.

The first course was taken by 120 students. Importance of the proper training is pointed out. Ha(11c)

Welding with the Oxy-illuminating Gas Process. H. H. LURIE (Purdue University.) *Bulletin, Utilities Research Commission*, Vol. 2, May 1931, pages 1–4.

Welding with city gas at the usual low pressure is impractical. By use of a booster to give higher pressures, special Mekker type tips, with injection of oxygen by means of high pressure gas, and a mantle of unmixed city gas outside the flame, welds of 80% efficiency were made in light gages of steel, up to $^1/_4''$ thick. Cast iron can be welded in much heavier cross sections, up to $1^1/_2'' \times 2''$ or more. By the line reversal method, the maximum flame temperature was determined as around 2600° C., against around 3100° C. for oxy-acetylene. Mixed city and natural gas in an 800 B. t. u. mixture, which will be available in many localities, should extend the range of welding with gas. HWG(11c)

Riveting (11d)

Riveting Methods in the Construction of Metal Airplanes. (Nietverfahren im Metall-Flugzeugbau.) W. PLEINES. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.–June 1931, pages 166–173.

A report of the Deutsche Versuchsanstalt für Luftfahrt. See *Metals & Alloys*, Vol. 2, May 1931, page 104. Ha(11d)

Sil-Fos

Brazing Alloy Patent Granted

The remarkable brazing qualities of this new alloy have been recognized by the granting of Patent No. 1,829,903.

SIL-FOS

1. Melts at 1300° F. (300 to 800° less than common brazing and welding rods).
2. Is free flowing—penetrates deeply and quickly and makes neat joints.
3. Makes strong, sound, ductile joints (tests show 30,000 to 35,000 lbs. per sq. in. on copper lap joints).
4. Joins copper, brass, bronze, extruded brass and bronze, nickel, monel and other non-ferrous metals.
5. Works fast—saves time.
6. Requires less than the usual amount of flux —none at all in some cases.
7. Joints are easy to clean.
8. Resists corrosion.
9. Contains silver.
10. Sold by the *pound* in standard strip, rods and pulverized, at surprisingly low prices for a silver alloy. In addition to its many advantages in working qualities, Sil-Fos is *economical* to use.

SIL-FOS Patent Rights *Will Be Protected.*

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

The Application of Temperature Measuring Instruments and Waste Gas Testers in the Open Hearth Furnaces. (Ueber die Anwendung von Temperatur-Messgeräten und Abgasprüfern an Siemens-Martin-Oefen.) W. LIESEGANG & W. WINKHAUS. *Archiv für Eisenhüttenwesen*, Vol. 4, Mar. 1931, pages 421–429; *Stahl und Eisen*, Vol. 51, Apr. 16, 1931, pages 497–498.

Report No. 148 of the Committee on Heat of the Verein deutscher Eisenhüttenleute. Temperature measuring instruments to control the open-hearth furnace are suitably installed in the checkers above the brick lining. Radiation pyrometers proved superior to thermocouples. Special installation devices, however, are necessary to guarantee proper readings. Otherwise, soot and water are deposited on the lens of the pyrometer, thus causing wrong readings. In order to avoid this, the pyrometer (Ardometer) is placed upon a water-cooled jacket and air is blown in front of the lens when readings are to be taken. The correctness of the readings depends upon the supposition that the radiating and sighted body is a black body. This holds true for the radiation of the checker investigated. The temperature distribution of the gas checker was studied and the difference was determined between the wall temperature and the gas temperature. The temperatures were compared with the readings of a flow pyrometer. It is shown that the temperature taken with the radiation pyrometer is approximately the temperature of the sighted wall but not the temperature of the gas. The second part of the paper refers to the taking of gas samples which should be done in the ports. A new type of gas taking device, provided with ceramic filter is described and has been successfully tested. The recorders of all controlling instruments are centrally installed on the furnace platform. GN(12a)

Zirconium Alloys in Steel Manufacture. PH. GUY. *Iron Age*, Vol. 127, June 11, 1931, page 1895.

Abstract translation of article in *Aciers Speciaux, Métaux et Alliages*, Nov. 1930. Discusses the use of Zr alloys for deoxidation and purification in steel making and the effect on the physical properties. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 147. VSP(12a)

Physical Chemistry of Basic Open Hearth Reactions during Melting. (Contribution a l'étude physico-chimique des réactions du four Martin basique pendant la période de fusion.) J. GERMEAU. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 151–156.

Brief discussion of the thermodynamics involved. HWG(12a)

The Manufacture of Cast Iron in the Electric Furnace. WALTER LISTER. *Foundry Trade Journal*, Vol. 43, Sept. 4, 1930, pages 165, 167.

According to author's experiences, Fe for molds over 3 tons capacity and up to 60 tons is made in basic electric furnaces. The electric Fe gives much better results than ordinary cupola Fe. Greater control can be exercised over analysis and melting conditions. Best method is to use 50% pig Fe and 50% steel scrap in the charge. For 10-ton charge about 4 cwts. of coal and 4 cwts. of lime should be added to make the slag. The operation takes about 4 hrs. and current consumption is about 450 kw.hrs./ton. The duplex method is used for the manufacture of high class castings. The process consists in transferring molten Fe from the cupola to the electric furnace and there superheating and refining it, and adjusting the analysis to desired specification. Includes tables giving comparative tests of cupola melted Fe before and after treatment in electric furnace, and also comparative costs. VSP(12a)

High Frequency Induction Melting for Quality Steels. (Remarques sur du four a induction a haute fréquence pour la fabrication des aciers l'emploifins.) M. LACROIX. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 217–225. 5 figures. 16 references; *Revue de Métallurgie*, Vol. 28, Mar. 1931, pages 151–161.

Describes installation and operation of the furnaces on a variety of steels. The oxidizing atmosphere is an inconvenience but the surface can be protected. HWG+JDG(12a)

Progress in Construction and Operation of the Coreless Induction Furnace for Making Steel. (Fortschritte in Bau und Betrieb des kernlosen Induktionsofens zur Stahlerzeugung.) N. BROGLIO. *Stahl und Eisen*, Vol. 51, May 14, 1931, pages 605–613; May 21, 1931, pages 635–644.

Report No. 208 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The report covers further results of the induction furnace of the Rüderoth Steel Works. (First report, *Stahl und Eisen*, Vol. 50, 1930, pages 617–629.) The life of the furnace crucible could be increased to such an extent that the furnace could be run continuously during a whole week without making repairs. Consumption of current and time are discussed on the basis of the energy balances established. The results are compared with the crucible process, the open hearth furnace and the electric arc furnace. This was done to illustrate the efficiency of the induction furnace. An essential advantage of the induction furnace is that very high temperatures can be reached. Although there is a possibility of producing unclean steels, a careful control of the furnace guarantees the production of high quality steels. An absolute absence of slag inclusions in the steel can also be achieved. The temperatures of the furnace can be controlled without difficulties. GN(12a)

Open-Hearth Furnace Control. MARTIN J. CONWAY. *Iron Age*, Vol. 128, July 23, 1931, pages 244–245, 278.

Includes discussion. Abstracted from a paper read at Cleveland, June 17, before the Combustion group of the Association of Iron & Steel Electrical Engineers. Discusses application of the control and gives results of calculations, showing pressures necessary in overcoming resistance to gas flow through the system. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 189. VSP(12a)

Modern Design and Operation of Open Hearth Furnaces. (Ueber neuzeitlichen Bau und Betrieb von Siemens-Martin-Oefen.) E. DIEPSCHLAG. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Aug. 8, 1931, pages 1005–1012.

The growing importance of the open hearth process is discussed and explained by economic necessity because the increased supply of scrap can be converted most economically in the open hearth process. The fuels for heating these furnaces are compared. On the basis of 1,200,000 kcal./ton, the required amount of fuel for 1 ton of steel is oil, 124.16 liters; tar, 104.57 liters; coal, 238.1 kg.; coke oven gas 306.12 m.³ The different kinds of mixed gases are discussed and the consumption/ton of steel is compared for different preheating of air. Constructive details of burners, hearth and tilting arrangements are illustrated. For the relation between size of furnace and economy, curves are developed, taken from furnaces in operation in all industrial countries. Fuel consumption decreases with capacity. Large open hearth furnaces should be built as tilting furnaces so the slag can be handled easily. 32 references. Ha(12a)

Melting of Gray and Malleable Iron in the Indirect-Arc Furnace. J. C. BENNETT & J. H. VOGEL. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Aug. 1931, pages 235–256.

The data on Fe qualities are discussed and the costs of operating indirect-arc melting furnaces are outlined. See *Metals & Alloys*, Vol. 2, July 1931, page 135. CHL(12a)

Causes of the Action of Thomas Slag. (Ursachen der Wirkung des Thomasmehls.) TH. DUNKEL. *Stahl und Eisen*, Vol. 51, June 25, 1931, pages 794–796.

The author reviews a paper by A. Wilhelmj in *Zeitschrift für Pflanzenerneuerung, Düngung und Bodenkultur*, A. 19, 1931, pages 129–239 on this subject. A very large number of Thomas slags of various origins were tested to determine their fertilizing value. All tests indicate that all Thomas slags with a higher content of "soluble" silica are superior to those with lower content of "soluble" silica. Wilhelmj points out that the steelmaker should process his Thomas slag with a higher percentage of silica. GN(12a)

Slag Reactions in the Basic Open Hearth. (Beiträge zur klärung der Schlackenfrage in Basischen Siemens-Martin-Ofen.) R. BACK. *Stahl und Eisen*, Vol. 51, Mar. 13, 1931, pages 317–324; Mar. 19, 1931, pages 351–360.

Report No. 204 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Including discussion. The investigations were carried on on 19 basic open hearth melts and the reactions during the melting and the boil were studied. The basicity as the variable of the relation $CaO:SiO_2$ was determined. It was found that even during the melting, the Fe loss increases with basicity, an occurrence which has its cause in the opposite behavior of SiO_2 and FeO and Fe_2O_3 in the slag. As to the loss of Mn, no simple relation similar to that found for the loss of Fe could be established. During the boil, both elements are lost increasingly with the basicity of the slag. The reactions, in particular those of Fe and Mn, were studied during the progress of the melt, from the beginning melting to the finishing of the heat under the presence of 5 various types of slags: a slag with high acid content, medium and normal acid content, a normal basic slag and a slag with a high content of bases. The acid slags unexpectedly gave favorable results as to the balance of the Mn. In the slags with medium basicity, the largest amount of Mn re-enters into the bath. With the basic and high basic slags, the reduction of Mn ceases. However, in these slags, the re-entering of Mn from the slag into the bath is favored by higher furnace temperatures. Similar conditions as to the reactions of Fe prevail during the boil. The above stated reactions of Mn must be explained by the behavior of Fe, inasmuch as the FeO content of the slag increases with the basicity and oxidizes Mn. The prevailing effect of the slags upon the reaction of Fe and Mn makes it advisable to study the composition of the slag more in detail during the making of the heat. 12 types of slags of various basicity are shown in pictures. GN(12a)

Casting & Solidification (12b)

Influence of Temperature and Cooling Conditions in Casting of Zinc. (Einfluss der Temperatur und der Abkühlungsverhältnisse beim Zink Giessen.) O. BAUER & P. ZUNKER. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 3–26.

Of the very exhaustive tests to elucidate the influences of temperature of pouring, temperature of ingot mold, wall thickness of the mold on the formation of pipes and nature of structure, the following principal results will be mentioned; for details, the paper with its many illustrations and tables must be referred to. When using a metal ingot mold with thick walls, the cast ingot showed at 420° C. (the lowest pouring temperature) the greatest pipe; with increasing temperature, the hollow space decreased and, from an average pouring temperature, it started to increase again. When using a stone mold, the pipes are greater than in ingots cast in metal molds. The structure shows long crystals while in metal ingots the structure shows fine crystals. Preheating of the mold results in greater pipes than an increase in pouring temperature; the size of the pipe increases almost linearly with increasing mold temperature; the pipes are deeper. The crystal structure is considerably coarser. The same results were obtained with a stone mold of great wall thickness but, due to the much more delayed cooling, the solidification by the air on top of the ingot is of greater importance and the formation of pipes in the interior is enhanced. The structure becomes coarser with increasing mold temperature. When such ingots were machined, cracks and splitting was a frequent occurrence. The tests were repeated with molds of only ½–2 mm. wall thickness. In general, the pipes were smaller than with thick walls; for 2 mm., they were smaller than for ½ mm. The structure is fine at 420° C., but soon becomes coarse at higher temperatures. Molds of thin wall thickness have the disadvantage that due to their great heating after pouring they warp easily and the ingot has a bad shape. The cooling requires much more time. If a mold with thin walls is water-cooled immediately after pouring, ingots with small pipes could be obtained; increased temperature also resulted here in bigger pipes. The crystal structure consists mostly of long needles. For different pouring velocities, the ingot cast most quickly had the biggest pipe; a decrease of pouring velocity also reduced the size of the pipe. On the other hand, the greater the pouring velocity, the finer the grain in the ingot; the finer the grain, the better the mechanical properties. Molds of thin walls seem to give, under special pouring conditions, fine grain with an unimportant-formation of pipes. Ha(12b)

Continuous Ingoting of Molten Metal. (Contribution a l'étude du l'ingotage continu des métaux en fusion. Procédé Douteur-Chantraine.) J. CHANTRAINE. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 95–102.

Proposal, with sketches from a patent, to avoid ingot molds and blooming mills by continuous casting of molten metal into a long bar of relatively small cross section, past moving chills. It was brought out in discussion that no apparatus had been constructed to test the idea though specific claims for saving 100 francs per ton were put forth. HWG(12b)

Unsoundness in Aluminium Sand-Castings. Part I. Pinholes: Their Causes and Prevention. Part II. The Effects of Using Metal Previously Subjected to Corrosive Conditions. D. HANSON & I. G. SLATER. *Institute of Metals, Advance Copy* No. 569, Sept. 1931, 29 pages; *Advance Copy* No. 570, Sept. 1931, 12 pages.

Part I. The presence of pinholes is probably caused by H absorbed in the molten alloy. The H probably results from the decomposition of water vapor by the molten Al. Pinholing was studied by casting in a tapered mold, sectioning the resulting casting and examining for unsoundness. Bubbling steam through molten Al and several Al alloys increased the unsoundness. Bubbling dry N through the alloys improved the soundness, but the effects of commercial gas, containing water, were deleterious. Cl in some cases improved soundness. A mixture of dry N and Cl was quite effective in laboratory experiments and in 60 lb. commercial melts. In 200–300 lb. melts, however, the treatment was not effective because it was necessary to heat the alloys to too high a temperature in order to permit the pouring of the entire melt. Treatment with $TiCl_4$ improved some alloys, but much fume was liberated when using this liquid. Additions of S, Se and Te in quantities up to 1% were studied. S increased the porosity. Se and Te in some alloys effected a slight improvement, but adversely affected the physical properties. Heating an alloy containing Zn to 950° C. and cooling to 750° C. before casting increased the soundness. A similar treatment of alloys containing up to 1% Cd did not produce a similar improvement. Contains 13 references.

Part II. Virgin Al and Al alloys that had been exposed to corrosive conditions were sand cast and examined for soundness. It was found that the unsoundness increased as the severity of corrosion increased. Storage in a dry room prior to casting produced but little unsoundness. Pickling and electrolytic treatment prior to melting also increased the unsoundness, but not as greatly as outdoor corrosion. It is suggested that the unsoundness results from the absorption of nascent H formed during corrosion. JLG(12b)

Practical Method to Avoid Pipes in Die Casting of Certain Pieces. (Procédé pratique p ur éviter les retassures dans la coulée en presse de certaines piéces.) J. CHARTIER. *Revue de Fonderie Moderne*, Vol. 25, July 10, 1931, page 241.

By arranging the single pieces in the mold vertically one above the other and casting from the bottom so that the metal rises from the lowest to the highest, no pipes will be formed if the metal is soft and has at least 3.3–3.5% Si. Ha(12b)

Contributions to the Question of Primary Crystallization. I, II. (Beiträge zur Frage der Primärkristallisation. I, II.) W. CLAUS & R. HENSEL. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 15, 1931, pages 399–408; May 29, 1931, pages 437–442; June 5, 1931, pages 459–464; June 12, 1931, pages 476–482; June 19, 1931, pages 499–502.

It has been recognized that besides the determination of the microstructure of a casting, the macrostructure is also of importance. The structure of a steel block cast in an ingot mold consists of a marginal zone of small crystallites, a transcrystallization zone of columnar crystals and a core or equiaxed range. The mechanical properties of the marginal zone and the core are considerably better than those of the transcrystallization zone which, for this reason, is an undesirable condition. The authors set out to determine the orientation of the primary crystallites for which 5 methods are discussed and described. The following conclusions were drawn: the marginal zone of a steel ingot is irregular. The transcrystallization zone is directed with one axis vertical to the cooling surface and columnar crystals are formed. The core is irregular. A crystallographic relation between core and transcrystallization zone could not be discovered but between transcrystallization and marginal zone a connection exists as the former grows out of the last layer of the irregular crystals. The second part deals with attempts to find the laws for the formation of the peculiar structure in steel ingots treated in part one. Of the very exhaustive discussions and descriptions of testing methods, the following review can be given in brief: It could be stated that under-cooling does not occur in cast metals; this cannot, therefore, originate the primary structure. Between 2 points of a melt in a metal mold, no temperature difference (except in the first moment) occurs The temperature of the cast melt after pouring drops immediately to the melting temperature and remains constant until solidification. To explain the crystallization by thermal reasons, it was assumed that an irregular structure is due either to a too fast heat conduction (effect of the mold) or to a too slow heat conduction (heat accumulation). From numerous experiments to determine the character of the structure as dependent on pouring temperature and mold conditions, it could be stated quite generally that all structural changes can well be explained by thermal conditions. 45 references supplement the paper. Ha(12b)

Large Steel Ingots for Forging. HERBERT H. ASHDOWN. *Iron Age*, Vol. 127, June 1931, pages 1888–1890.

Based on paper read at the Chicago meeting of the American Society for Steel Treating. Includes discussion. Rotating molds for forging ingots during casting accelerates solidification, thereby arresting segregation and insuring uniform analysis. See "Steel Ingots," *Metals & Alloys*, Vol. 2, July 1931, page 135. VSP(12b)

Prevent Losses with Proper Gates and Risers. PAT DWYER. *Foundry*, Vol. 59, Jan. 1, 1931, pages 56–60; Aug. 15, 1931, pages 35–37, 41.

Lack of practical knowledge on such points as gating, risers, shrink heads and suitable pressure for light or heavy castings is still a cause of a great number of defective castings. In some instances the size, shape and position of the gate are of major importance. Clean castings are secured by pouring the Fe through a multiplicity of small pop gates on the top. Experienced molder should devise the most suitable method of gating and heading each casting. Pressure is important factor in securing solid castings. Porous and spongy castings are caused by too many risers and shrink heads. The fifteenth of the series deals with the various types of gates and risers used in the foundry industry. A feature of roll pouring methods might be adopted in the production of many other castings. The pouring basin is set at a height that will insure its complete evacuation by the time the metal has risen to the top of the mold. The only scrap iron produced is the metal remaining in sprue, gate and sink head. On large castings, it is customary to introduce the first metal at the bottom of the mold, then pouring remainder down through pop gates at the top. VSP(12b)

Cast Aluminum Bronzes. III. Shrinkage Phenomena. IV. Theory of Shrinking. V. Mechanical-Technological Properties. (Gegossene Aluminiumbronzen. III. Schwindungserscheinungen. IV. Theorie der Schwindung. V. Mechanisch-technologische Eigenschaften.) W. CLAUS & F. GOEDERITZ. *Die Giesserei mit Giesserei-Zeitung*, Vol. 17, Oct. 17, 1930, pages 1017–1023; Vol. 18, Apr. 17, 1931, pages 319–326; Apr. 24, 1931, pages 340–346.

In studying the macrostructure of cast Al bronzes, castings of 4.5, 7 and 10% Al, and a Si-Al bronze are made in dry and moist sand and in chill molds, pouring at 1250°. Shrinkage pipe is present in the core of the 7 and 10% Al bronzes when cast in either the dry or the moist molds. The 4.5% Al bronze shows small defects in the bottom of the casting, but no shrinkage pipe in the head. This bronze when cast in a chill mold gives a dense casting. Shrinkage pipe is shown by the 4.5, 7 and 10% bronzes when cast in chill molds. The Si-Al bronze shows slag defects in the foot when cast in the sand molds and a central porosity when cast in the chill mold. Lower pouring temperatures (1050°) do not affect the shrinkage pipe in the 10% Al bronze when cast in the dry sand mold. The comparative discussion of shrinking of Al and Sn bronzes shows that the linear shrinkage measures do not give a critical value. The values of cubical shrinking and the reduction to linear shrinking do not give a correct measure, either. The extraordinary difference between the 2 kinds of bronzes seems to point to an absolutely different distribution of the same total shrinkage to the liquid and solid phase, respectively. Macro-formation of pipes can take place at unfavorable solidification velocity. In all binary Al bronzes, intercrystalline micro-formation of pipes takes place besides the macroformation. Dry casting of binary Al bronzes in vertical molds has throughout given poor qualities of mechanical strength which, under certain conditions, may be improved by casting in horizontal dry molds. Metal mold casts always produced a technically excellent material. Binary Al bronzes cannot be cast in sand. The test results for tensile and bending and hardness, etc. are tabulated; 25 references and a list of publications are cited. Ha(12b)

On the Formation of Graphite in Cast Iron. (Ueber die Graphitbildung im Gusseisen.) H. HANEMANN. *Stahl und Eisen*, Vol. 51, July 30, 1931, pages 966–967.

It is shown by microscopic examinations of water-quenched cast iron specimens (C, 4.15%; Si, 0.09%; Mn, 0.18%) that the graphite is formed even during the solidification directly in the melt and not by disintegration of cementite. GN(12b)

Rolling (12c)

Theoretical and Practical Power Consumption during Rolling. (Theoretischer und praktischer Arbeitsbedarf beim Walzen.) A. GELEGI. *Stahl und Eisen*, Vol. 51, July 9, 1931, pages 886–887.

Abstract of a paper presented before the Hungarian Society of Engineers and Architects, Feb. 15, 1930. A simple formula has been developed to calculate the power consumption in rolling common shapes. GN(12c)

Determination of the Neutral Line of a Pass. (Beitrag zur Bestimmung der neutralen Linie eines Kalibers.) W. DAHL. *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 633–635.

Report No. 85 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. A new method for determining the line of rolling mill passes is described. It is shown by examples that the new method gives the same results as Tafel's method, but it is simpler and can also be used for intricate shapes where Tafel's method fails. GN(12c)

Chilled Cast-Iron Rolls, Their Failure and Its Causes. (Hartgusswalzen, ihre Fehler und deren Ursachen.) W. BREITENBACH. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 6, 1931, pages 206–209.

It is contented that most failures of rolls which are ascribed to defective materials are, in reality, due to faulty treatment in the rolling mill. A few failures which occur more frequently such as breaking of pinions, cracks in the roll surface, etc., are discussed. Their causes are explained and suggestions are made for coöperation with the foundry. Ha(12c)

Sheet and Tinplate Rolls. An Investigation into the Roll Loads, Stresses and the Causes of Roll Breakage. J. SELWYN CASWELL. *Proceedings South Wales Institution of Engineers*, Vol. 46, Aug. 22, 1930, pages 311–452; *Sheet Metal Industries*, Vo. 4, Oct. 1930, pages 429–434; Nov. 1930, pages 523–531.

After discussing the manufacture of sheet and Sn-plate rolls, the author presents data gathered over a year's time in 29 sheet and 28 Sn-plate mills. On roll breakage, temperature variations in the mills, loads carried by sheet and Sn-plate rolls, torsional loads, physical properties of gray and chilled roll Fe, the magnitude and variation of the stresses in the rolls set up (1) in the foundry, (2) by the mill loads, (3) by thermal strains and (4) by other causes and hair-cracks and firemarks on the faces of fracture. The ratio of number of rolls broken annually to number of mills is approximately 1.8 for Sn-plate and 4.0 for sheet mills. Average life of rolls is 16 weeks and 8 weeks for Sn-plate and sheet mill rolls, respectively. In Sn-plate mills, life depends chiefly on the life of the chill; in sheet mills, on breakage. Greatest breakage is in winter. 82% broke through the body. Breakage is more frequent with large diameter rolls. Maximum loads in Sn-plate roughing mill = 500 tons; in finishing mill = 420 tons; in sheet mill = 1140 tons. Maximum torque is approximately 17,000 in.-ton. WHB+AWM(12c)

Rolling Alloys of Copper and Phosphorus. OWEN W. ELLIS. *Iron Age*, Vol. 127, June 4, 1931, page 1818; *Engineering*, Vol. 131, Mar. 13, 1931, page 376; abstracted in *Engineer*, Vol. 151, Apr. 3, 1931, page 374.

Abstract of a paper read before the Institute of Metals, Mar. 1931. Discusses results of rolling experiments on alloys of Cu with 2–6% P, with and without the addition of 5, 10 or 15% Mn or Ni. Discussed in *Engineering*, Vol. 131, Mar. 27, 1931, page 411. See *Metals & Alloys*, Vol. 2, July 1931, page 135. LFM(12c)

Continuous Billet and Bar Mill of the Trinec Mining and Steel Company. (Kontinuierliches Knüppel- und Platinenwalzwerk der Berg- und Hüttenwerksgesellschaft, Eisenwerk Trinec.) W. BRUNS. *Stahl und Eisen*, Vol. 51, Apr. 30, 1931, pages 547–554.

The article gives a detailed and illustrated description of a continuous billet and bar mill built by the Demag Company at the above steel mill in 1930. The new mills are distinguished by the variety of the rolling program and the possibility of easily and rapidly changing the schedule. The article gives information on rolling schedule, operation, capacity and the crew of the mills. GN(12c)

New Separation Machine for Sheets. (Neue Aufreissmaschine für Feinbleche.) F. CHRIST. *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 648–649.

Since the sticking together of rolled double sheets causes loss of time and since the separating of these sheets is done only by hand at present, the Demag Company, Duisburg, has built a special machine for this purpose. An illustrated description of the new machine is given. GN(12c)

High Production Cooling Beds. (Hochleistungs-Kühlbetten.) E. KÄSTEL. *Stahl und Eisen*, Vol. 51, June 18, 1931, pages 764–767.

The article gives an illustrated description of new constructions of high production cooling beds by Krupp. The constructions are described in detail. GN(12c)

Machining (12g)

Latest Developments of Faster Milling. FRANK W. CURTIS. *Western Machinery World*, Vol. 22, June 1931, pages 242–244; July 1931, pages 291–294; Aug. 1931, pages 342–343.

The first of a series of articles regarding the use and application of tungsten and tantalum carbide cutters. Milling with carbide has not kept abreast with its application to other forms of metal cutting operations, largely because early experiments failed to show comparable results. The cost involved was not justified because no guarantee of performance was offered. It has only been within the past few months that manufacturers have come to realize the importance attached to the application of tungsten carbide to milling cutters. The article is more or less introductory. The design of a milling cutter as applied to the application of tungsten carbide is presented. In the second of a series of articles on this subject, a chart is given showing horsepower against table feed in inches per minute, for 5 inch diameter face milling cutters on cast iron, with 0.125 in. depth of cut and $4^1/_4$ inches width of cut. Curves are given for high speed steel at 76 ft./min., stellite at 130 ft./min., tungsten carbide at 250, 300 and 375 ft./min., the horsepower required increases in that order. A diagram is given showing a typical cutter designed for the machining of soft or medium cast iron. The third of this series of articles dealing with the use and application of tungsten and tantalum carbide milling cutters describes and illustrates the set-up used in milling of complicated cast iron shapes. WAT(12g)

Milling with Tungsten and Tantalum Carbide Cutters. FRANK W. CURTIS. *American Machinist*, Vol. 74, Jan. 29, 1931, pages 211–213; *Carboloy*, Vol. 4, May-July 1931, pages 5–15; *S. A. E. Journal*, Vol. 29, Sept. 1931, pages 232–235.

Application of tungsten carbide to milling is said to have lagged because results did not seem to justify the cost until modified cutter design was developed. Cutter angles that have proved satisfactory are given, and designs of cutters are shown. Rigidity in cutter, machine and fixture is emphasized as an important requirement and numerous examples of speeds and feeds are cited. Successful use of tantalum carbide for milling steel is reported and the paper concludes with a list of suggestions for the successful introduction of milling with these 2 cutting materials. Drawing & Stamping (12h)

Fabrication of Aircraft Stampings. T. WATSON DOWNES. *Metal Stampings*, Vol. 3, Aug. 1930, pages 731–732.

Abstract of paper read before the American Society for Testing Materials. See "Metal Joints in Aircraft Construction," *Metals & Alloys*, Vol. 1, Nov. 1930, page 850. MS(12h)

Standard Die Parts. ELLSWORTH E. CLARK. *Metal Stampings*, Vol. 3. Nov. 1930, pages 991–994; Dec. 1930, pages 1095–1098.

Discusses developments in standardization of die parts and advantages thereof. Gives practical illustrations of the application of standard parts and methods in the construction of metal-stamping dies. MS(12h)

Standard Brake Dies of Simple Design. GLENN A. BARTH. *Metal Stampings*, Vol. 3, Nov. 1930, pages 1007–1008.

Deals with development of ridge-roll and corrugation-forming dies for press brakes. MS(12h)

Applications of Sealing Metal in Die Construction. ELLSWORTH E. CLARK (Westinghouse Elec. & Mfg. Co.). *Metal Stampings*, Vol. 4, Mar. 1931, pages 225–228.

The specifications and requirements for a suitable sealing metal alloy are defined. The design of a complicated compound die and its construction with the aid of sealing metal is described in detail. The advantages of this method of die construction and some of the precautions to be observed in its utilization are cited. JN(12h)

The Application of Welding to Die Construction. ELLSWORTH E. CLARK (Westinghouse Elec. & Mfg. Co.). *Metal Stampings*, Vol. 4, Feb. 1931, pages 113–117.

Gives new method developed by the author for fabricating dies by the arc welding process. As an illustration, he describes the complete manufacture of a die set from machine steel plates for forming a shallow drawn shell. Also gives examples of correct and incorrect designs of various welded joints. Claims cost reductions in both labor and materials and urges that die builders look into this method. JN(12h)

Aluminum Sheet for Stamping and Drawing. R. J. ANDERSON. *Metal Stampings*, Vol. 3, Dec. 1930, pages 1087–1089; Vol. 4, Feb. 1931, pages 137–140.

Aluminum sheet increases in both hardness and tensile strength up to a certain limit when cold worked. The percentage elongation, however, decreases rapidly to a fixed low value as the hardness increases. The author gives a table of temper designations, tensile strengths and percentage elongations for 16-gage 2S and 3S aluminum sheet of various degrees of hardness from dead soft to full hard. The elongation is a measure of the drawability of the sheet and an indication of its purity. The temper is usually determined by means of the Shore scleroscope. The bending test, which consists in bending a narrow strip of sheet upon itself, is a useful indication of workability. The most reliable test for drawability is the cupping or ductility test, which closely simulates draw-press action. This is performed on either the Olsen or the Erichsen machine. The cupping test value depends on the temper, thickness, composition, grain size and general quality of the sheet and readily identifies unsuitable material. Coiled aluminum sheet is usually supplied in widths from 1 to 21 in. and from 10 to 36 gage. These coils weigh 40 to 60 lbs. Coil circles are made in almost any practical width from 4 in. to 20 in. and down to 30 gage. Flat sheet varies from 1 in. to 60 in. in width and runs up to 180 in. in length. Bright flat sheet ranges from 10 to 36 gage while gray plate is usually not made lighter than 20 gage. The second part discusses range of sizes, grades and qualities available. Bulk of sheet for drawing purposes is made in the dead-soft temper. 2 grades (2S and 3S) are generally used in the manufacture of drawn and stamped shapes. Commercially pure Al sheet is known as 2S; 3S contains 1.25% Mn and the remainder Al. Great bulk of material used by the stamper is in the form of coils and coil circles, gray-plate strips being used in lesser quantity. Includes table giving Brown and Sharpe gage, thickness in inches and weight in lbs./ft.^{2} of Al sheet ranging from 10–36 gage, the usual range employed in the stamping trades. JN(12h)

Tests on the Properties of Drawn Wire and Power Consumption during the Drawing Process. (Versuche über die Eigenschaften gezogener Drähte und den Kraftbedarf beim Drahtziehen.) W. LINICUS. *Zeitschrift für Metallkunde*, Vol. 23, July 1931, pages 205–210.

The paper discusses the following: properties of drawn brass wires as dependent on the conditions of drawing, comparison between drawn wires and those stretched by pulling; effect of uneven flow of material during the drawing process upon the properties; additional strain hardening and internal stresses due to stretching; hardening of the edge; power consumption during drawing; loss in friction and true share of pulling strength required for the plastic deformation; influence of uneven material flow upon power consumption; checking of theoretical considerations concerning the power consumption with particular reference to the total power required in addition to the pulling stress; influence of die material and influence of the qualities of the rolling material upon properties of the rolled material and upon the power consumption; utilization of laws found on other materials. EF(12h)

Internal Stresses in Brass Tubes. (Innenspannungen in Messingröhren.) A. KRECEK. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, pages 178–185.

The occurrence of large and uneven internal stresses in brass tubes (62–65% Cu) which were drawn with small reductions in diameter and wall thickness precipitated the present investigation. Any influence on the side of varying Cu contents and of micro-structural differences could not be proved whereas there is an important influence due to method of diameter and wall-thickness reductions, form of dies, lubrication and kind of straightening devices. The author furthermore revealed the role which the dimensions of samples submitted to the determination of internal stresses and the accomplishment of the mercury nitrate submersion test are playing. Fundamental principles involved in the evaluation of tension reduction free from stresses are considered. EF(12h)

Forming of Large Stampings for Aircraft. R. E. JOHNSTON. *Metal Stampings*, Vol. 4, Feb. 1931, pages 159–160.

Aluminum alloy sheet is now widely used in airplane construction. The sheet metal department employs a large variety of presses, shears, rolls, saws, etc. A 700-ton hydraulic press with platen 129 in. × 60 in. is used to form large parts for the tail assembly, cowling, fuel tanks, seats, flooring, etc. The required dies are made of reënforced hard maple or of cast steel. This press shapes parts from duralumin, alclad, aluminum, brass, copper and steel. The sheet metal ranges from $^1/_{100}$ to $^1/_8$ in. in thickness. JN(12h)

Machines and Tools for Forming. (Werkzeugmaschinen und Werkzeuge der spanlosen Formgebung.) H. HAAKE. *Maschinenbau*, Vol. 10, June 4, 1931, pages 387–391.

Hot- and cold-working by hammering and in forging machine; rolling out into sheets by cutting, turning, bending; shaping stamping tools as an important new development; progress in construction of special stamping tools; hydraulic and mechanically operated stamping machines; preference for simple crank and eccentric presses for use of pneumatically tested tools; measurement of the power in working machines; the variety (multiplicity) of couplings; increasing safety and load by automatic feeding and removal of tool pieces; special machines. MAB(12h)

The Drawing of Non-ferrous Wires. E. L. FRANCIS & F. C. THOMPSON (Victoria University of Manchester). *Institute of Metals, Advance Copy* No. 568, Sept. 1931, 25 pages.

Tests showed that the tension required to pull a wire through a die is independent of the speed, at least for speeds between 0.0001 and 600 ft./min. The pull is directly proportional to the original tensile strength of the wire. The tension is also proportional to the reduction of area effected. Experiments with various die angles indicated that the smallest tension was required when the semi-angle was between $5^1/_2°$ and 6°. This was for a 20 and a 35% reduction. The best lubricant was a Na soap, but wires of better appearance were obtained with liquid lubricants. A mixture of graphite and oil, "oil-dag," was found to be the best non-solid lubricant. The friction in tungsten carbide dies was less than that in steel dies. This was attributed to the better lubrication of the former due to the inhomogeneity of the microstructure. With liquid lubricants the friction was less in diamond dies than in tungsten carbide dies. Greater tension was required to pull wire through bell-shaped dies than through conical dies. 12 references. JLG(12h)

Accurate Stamping of Dials and High-Grade Nameplates. FRANK V. FAULHABER. *Metal Stampings*, Vol. 3, Dec. 1930, pages 1075–1078.

Gives suggestions for overcoming delays, improving the product, and lessening waste of material and spoilage in the punching of holes, blanking out and other stamping operations where great accuracy is required. MS(12h)

Flow Phenomena in Deep Drawing of Sheet Metal. I. FETSCHENKO-TSCHOPIWIKI & M. OPALKO. *Metal Stampings*, Vol. 3, Nov. 1930, pages 1027–1029; Dec. 1930, pages 1115–1116, 1125.

Translated from *Zeitschrift des Oberschlesischen Berg- und Hüttenmännischen Vereins*, Vol. 69, Dec. 1930, pages 652–658. Sheet-metal normally shows indications of cold working in the form of flow figures on the surface. These flow lines influence the stamping qualities of the metal and the direction of cracks in the Erichsen test. A compression test in which deep drawing takes place at an angle of 30–35° is useful in determining the suitability of steel sheets for deep drawing purposes. Good sheets yield a smooth, straight surface after the stamping. Coarse, crystalline material will always produce cracks, as well as a coarse surface. Good stamping properties can be attained if the C content is 0.09–0.11% and Mn, 0.40–0.50%. Thermal treatment has marked influence on deep drawing properties. Annealing in a temperature range between Ar_3 and Ar_1 favors formation of free cementite at expense of pearlite. As a result, the material becomes very brittle, and in deep stamping, cracks and a coarse surface occurs. Long annealing at temperatures below the allotropic transformation improves drawing properties but produces a certain degree of brittleness. Erichsen test, under such conditions, shows satisfactory results, whereas the deep stamping test causes a rupture. It follows, therefore, that it is necessary to anneal deep drawing stock at temperatures above the allotropic transformations and to cool rapidly, so as to attain a fine crystalline structure and to prevent accumulation of free cementite at the grain boundaries. MS(12h)

Maintenance of Stamping Plant Equipment. L. B. HORNBERGER. *Metal Stampings*, Vol. 3, Nov. 1930, pages 981–984.

Discusses some important maintenance problems encountered with heavy stamping equipment. Points out that a special maintenance department provides systematic inspection and servicing. MS(12h)

Important Considerations in the Checking of Punch and Die Work. ROBERT A. HEYDEN. *Metal Stampings*, Vol. 3, Dec. 1930, pages 1101–1102.

List of questions regarding important points of design. Applicable to blanking and perforating and blanking punches and dies. MS(12h)

The Construction and Uses of Typical Dies. Parts II, III. EDWARD HELLER. *Metal Stampings*, Vol. 4, Feb. 1931, pages 153–154, 166; Mar. 1931, pages 233–234, 242.

Part II. A discussion of 3 types of combination dies. These are all made by adding a piercing operation to a blanking die. The most common type combines the piercing and blanking operations in sequence. A second type, the "compound die" blanks and pierces in one operation, while the third type, which requires a sequence of motions, must be used when the piercing operation is performed close to the edge of the blank. Part III. The design and detailed construction of 3 types of dies with their applications and methods of operation are described. The piercing, cutting and forming type of die makes a small channel in a stamping. The simple forming die bends up small pieces of sheet metal into various shapes. The forming die with a collapsible punch permits the punch to collapse on the up-stroke of the press so as to facilitate the removal of the finished piece. JN(12h)

Pickling (12i)

The Pickling and Cleaning of Metals. II and III. Some Considerations of the Chemical Reactions Involved. DAVID BROWNLIE. *Sheet Metal Industries*, Vol. 4, Oct. 1930, pages 425–427; Nov. 1930, pages 519–520.

The author elaborates on his statement in Part I that corrosion is due to electrical as well as chemical action. He points out the theories of corrosion resulting from electrolytic action and sets forth the relation between theory and practice in the case of pickling where it is desired to remove only the scale. By placing a boiler under definite potential through dynamo connections it has been found that corrosion can be made to cease immediately, even when using salt water, and existing scale comes off. It is suggested that this could be applied to an improved pickling practice. Part III discusses, generally, inhibitors and restrainers used and available for pickling baths. AWM(12i)

Acid Inhibitors in the Pickling of Metals. (Les Economiseurs d'acide dans le d'capage.) GEORGES BATTA & EDM. LECLERC. *Chimie et Industrie*, Vol. 25, Special Number, Mar. 1931, pages 475–483.

The results obtained by adding various inhibitors (gelatin, CH_2O, flour, Na_2AsO_3, anthracene oil from coke ovens and commercial products) to a 20% HCl bath and a 10% H_2SO_4 bath are described. The method used consisted in measuring the volume of H evolved on immersing cleaned sheets of the metal for a given time in the pickling bath, and was found quite satisfactory for comparative purposes. The cleaning of the metal surface before the test considerably affects the results, a much greater evolution of H being obtained by polishing the surface than by cleaning with acid, H_2O and ether, which is attributed to some of the H remaining occluded to the surface of the acid-cleaned metal. In every case, the addition of inhibitor reduced the surface tension of the bath. The value of an acid inhibitor can be determined to a satisfactory degree of approximation by the following tests: (1) determining retardation in the solution of the metal by (a) comparing the losses in weight of identical samples of metal to be treated under the same conditions, in presence and absence of the required amount of inhibitor or (b) by comparing the volume of H evolved; (2) pickling tests consisting in immersing weighed unpickled samples in baths with and without inhibitor and comparing (a) loss in weight, (b) time required for pickling, (c) number of samples which can be pickled in a given volume of bath, (d) appearance of the pickled metal; (3) resistance of the inhibitor to the action of hot concentrated solutions, by heating the bath 6–12 hrs. and then determining the volume of H evolved with a standard sample of the metal. Cold Working (12j)

Why Cold-Working Changes Properties of Metal. E. V. CRANE. *Iron Age*, Vol. 128, Sept. 3, 1931, pages 626–630.

This is the third installment of a series of 4 articles on strain hardening. Explains why physical properties of metal change in the process of cold working with or without intermediate annealing. VSP (12j)

On the Cold-Working of Iron. (Sur l'écrouissage du fer.) W. BRONIEWSKI & J. KRÓL. *Comptes Rendus*, Vol. 193, July 6, 1931, pages 38–40.

The authors describe a series of experiments conducted on Armco iron of French manufacture, containing less than 0.15% total impurities. The article is accompanied by 2 diagrams showing (1) the effect of drawing this material upon the elastic limit, tensile strength, percentage elongation and Brinell hardness; (2) the effect of annealing on the hardness and the crystal size of the material; and (3) the effect of various annealing times on the hardness. OWE(12j)

Cold Roll Forming of Metals. Pt. X-XI. D. A. JOHNSTON. *Metal Stampings*, Vol. 3, Nov. 1930, pages 987–990; Dec. 1930, pages 1081–1084.

Discusses factors involved in the design of rolls and accessories necessary to form a special tube-like section with hemmed edge, and the principles of construction and application of combination rolls in the forming of sheet-metal sections. MS(12j)

DEFECTS (13)

What a Heat Treater Should Know about Defects in Steel. GEORGE M. ENOS. *Fuels & Furnaces*, Vol. 8, Nov. 1930, pages 1485–1490, 1542; Dec. 1930, pages 1631–1636.

Outlines methods of examining defective steel and discusses failures due to inclusions, pipe, segregation, etc., in the steel; improper hot or cold work; improper design; faulty heat treating; poor machine-shop or fabricating processes; and use of part in service under stress conditions not originally contemplated. MS(13)

Detecting Defects by Radiography, Using Gamma Rays. CHARLES W. BRIGGS & ROY A. GEZELIUS. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, July 1931, pages 65–92

γ-rays from radium are used to detect internal defects in steel castings. The method is illustrated by a series of radiographs taken on several castings. Film records are correlated with defects found upon subsequent sectioning of the casting. CHL(13)

On Soldering Brittleness. (Ueber Lötbrüchigkeit.) K. KREITZ. *Stahl und Eisen*, Vol. 51, Sept. 3, 1931, pages 1118–1119.

Soldering brittleness is due to the penetration of the soldering metals into the steel and can be avoided when tension stresses are absent during soldering. GN(13)

The Investigation of Sand Inclusions in Steel by Means of the Polarization Microscope. (Die Untersuchung von Sandeinschlüssen im Stahl mit Hilfe des Polarisationsmikroskops.) F. HARTMANN. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 601–606.

Report 174 of the Committee on Materials of the Verein deutscher Eisenhüttenleute. Slags and inclusions of refractories in steel can be distinguished by examining thin sections in the polarization microscope. The origin of refractory inclusions can be detected in comparing the thin sections with those of refractory materials which were in contact with the steel during the process of making. This method offers a possibility of improving the quality of refractories in order to avoid inclusions in the future. GN(13)

The Decarburization on the Edge of Carbon Steels with Simultaneous Scaling. (Die Beurteilung der Randentkohlung von Kohlenstoffstählen bei gleichzeitiger Verzunderung.) E. H. KLEIN. *Stahl und Eisen*, Vol. 51, Aug. 20, 1931, page 1066.

It was found that, during the heat treatment of carbon steels, samples which scaled were less decarburized than those which did not scale. It is, therefore, advised in judging the decarburization of steels to consider, also, the loss due to scaling. GN(13)

Inclusions and their Effect on Impact of Steel. A. B. KINZEL & WALTER CRAFTS. *Iron Age*, Vol. 127, Mar. 5, 1931, pages 781–783.

Abstracts of a paper read before the A. I. M. E., Feb. 18, 1931. Includes discussion. See *Metals & Alloys*, Vol. 2, July, 1931, page 136. VSP(13)

Inclusions and Their Effect on Impact Strength of Steel. II. A. B. KINZEL & WALTER CRAFTS. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 436, Sept. 1931, 10 pages.

Samples from 19 commercial heats of steel were heat treated to give Rockwell B hardness values between 76 and 96. Inclusion counts and transverse tensile-impact tests were made by the methods described in Part I (*Metals & Alloys*, Vol. 2, July 1931, page 136). The tensile-impact test was found to be a satisfactory method for the determination of the dynamic properties, but inclusion count alone was not. It is claimed that the importance of unknown factors comprised in the term "body" as distinct from cleanliness has been demonstrated. Practical limits for transverse tensile-impact strength for steels having Rockwell hardness values between 76B and 96B are suggested. JLG(13)

Embrittlement of Structural Steel. Progress Report of Sub-Committee X of Committee A5, A. S. T. M. V. F. HAMMEL, Chairman. *Advance copy*, to appear in Vol. 31, Part I, *Proceedings American Society for Testing Materials*, 1931, 27 pages.

Includes selected bibliography by S. Epstein and B. N. Daniloff of 175 titles, on blue-heat phenomena, chemical composition and melting procedure, cold work and reheating, pickling, caustic embrittlement, embrittlement of malleable, effect of heat-treatment and embrittlement testing. In rare cases, galvanized structural steel has broken with a brittle fracture under impact. In all such cases, the material has been punched stock. Theories for the cause include hydrogen embrittlement due to pickling, work hardening due to punching, precipitation hardening at galvanizing temperatures, or the combination of several factors no one of which alone would impair the properties seriously. Chemical composition is important, Bessemer steel being inherently more brittle than open-hearth, and normally being excluded from use for heavy angles for transmission towers. Work hardening due to punching is a major factor in producing brittleness. Brittleness is more pronounced at low temperatures. Susceptibility to these embrittling factors varies in different types of steel and to some extent in different heats. Testing for brittleness is carried out by bending a full-sized punched angle to fracture, the "angle bend test." This is a rough test unless made in quantitative fashion. Tensile or bend tests of coupons containing a punched hole also differentiate steel as to degree of embrittlement. These tests and the temperatures at which they are made, need standardization. Preliminary work on this problem for the Utilities Research Commission and for the A.S.T.M. included 2000 tests from 50 heats of steel. Based on the preliminary results, a further research program is outlined to lead to an acceptable test method, to recommended practices for manufacture, pickling, galvanizing and method of making the rivet-holes and to a better understanding of the causes for embrittlement. This includes, among other things, the study of pickling variables, of duplex steel and of the possible effect of N. Material from many sources and in all stages from rolling to galvanizing, is being studied. The study is under the joint auspices of steel makers, galvanizers, fabricators, zinc producers and users of galvanized structural steel, especially public utilities. The steering committee for the co-operative project represents all these interests. The reasons for the inception of the work, a brief statement of the extent of present knowledge and a list of some of the points on which further tests are needed are given. Since the work is only partly complete, no attempt is made in this progress report to prove the correctness of any theory or to set up any specifications or recommended practices, pending completion of research. CHEMICAL ANALYSIS (14)

Oxidation of Ferrous Iron by Iodine in Presence of Phosphate and Non-Existence of a Ferriphosphate Complex. WALTER D. BONNER & HENDRICK ROMEYN, JR. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 85–87.

7 references. The oxidation of ferrous iron in presence of phosphate and of a moderate concentration of acid goes to completion but the reaction, even in almost neutral solutions, is too slow to be of analytical significance. MEH (14)

The Volumetric Determination of Barium by Direct Titration with Potassium Chromate. (Massanalytische Bestimmung von Barium durch direkte Titration mit Kaliumchromatlösung.) S. BALACHOWSKI. *Zeitschrift für analytische Chemie*, Vol. 82, No. 617, pages 206–210.

The neutral $Ba(NO_3)_2$ solution is titrated with K_2CrO_4 using bromothymol blue or phenol-red as indicator; to both of these reagents K_2CrO_4 reacts alkaline and, hence, a characteristic color change is observed when all the Ba is precipitated. This method is adapted for microchemical analysis. Ha(14)

Determination of Aluminum in Ferrochromium and Chromium Metal. THOS. R. CUNNINGHAM. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 103–104.

In this method, Fe is separated by means of cupferron while Cr is oxidized by evaporating the solution with perchloric acid, and Al is separated by precipitation with ammonia. MEH(14)

Determination of Zirconium in Plain Carbon and Alloy Steels. THOS. R. CUNNINGHAM & R. J. PRICE. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, January 15, 1931, pages 104–106.

Zr is separated from other elements as $ZrHPO_4$ which is converted to ZrP_2O_7 on ignition. A determination may be completed on steels free from W, Sn, Ta or Cb in not more than 2 hrs. The method described is designed to be applicable to any commercial steel. MEH(14)

The Application of the Potentiometric Volumetric Analysis in the Steel Plant Laboratory. Part I. The Determination of Manganese, Chromium and Vanadium Simultaneously. (Die Anwendung der potentiometrischen Massanalyse im Eisenhüttenlaboratorium. I. Die Bestimmung von Mangan, Chrom und Vanadin nebeneinander.) P. DICKENS & G. THANHEISER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 14, 1930, Report No. 158, pages 203–223.

The paper reports the results of investigations on the titration of Mn, Cr and V with solutions of titanium salts. Further experiments were carried on to determine how other elements such as Ni, Co, Mo, Cu and W affect the titration of the above mentioned metals. These metals do not disturb titration. The advantages of the potentiometric titration are rapidity and exactness. See *Metals & Alloys*, Vol. 2, July 1930, page 634. GN(14)

Sampling and Analysis of Red Brass and Other Alloys Having a Tendency to Segregation. (Zur Probenahme und Analyse von Rotguss und anderen zur Seigerung neigenden Legierungen.) O. BAUER & E. DEISS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 139–142.

It is noted that the great differences often met in analyses of the same composition of ingots can be traced to segregation. This contention was proved by analyzing an ingot of red brass which was divided into several parallel strips, which showed that the contents of Cu increases greatly from the outside to the interior at the sides and the bottom. Sn and, to a lesser extent Pb, are also accumulated greatly in the exterior layers and decrease toward the center. The contents of Zn were fairly constant in all layers. The usually low amount of Sb decreased from the exterior to the center. The amounts of other unimportant metals contained in the alloy do not differ greatly in the different zones. The arrangement of the tests and the results are described in detail and recommendations added how to take samples in order to obtain an average analysis. Ha(14)

Atomic Analysis by Optical Spectroscopy. C. E. EDDY. *Chemical Engineering & Mining Review*, Vol. 23, May 5, 1931, pages 309–312.

An abstract of a lecture delivered at Melbourne University, Apr. 14, 1931. Spectroscopic methods are briefly described, and a different method of plate analysis has been developed in the laboratory of the university. It gives good results for plates taken on a Hilger quartz spectrograph. It produces a spectrum covering a 10″ plate. The plate has been calibrated so that from the position of any line, measured from a fiducial mark on the plate, its wavelength can be instantly and accurately determined. To determine the elements present in an unknown sample, it is only necessary to look for the ultimate lines in certain known positions on the plate. Advantages and disadvantages of the optical method of analysis are listed. Of the 27 elements discovered since 1860, 15 have been discovered as a result of optical spectroscopy, 4 by X-ray spectroscopy, 2 by their radioactive properties and 6 by their chemical properties. It has been conclusively demonstrated that the optical method is particularly suitable for carrying out: (1) complete qualitative analyses of unknown quantities and (2) rapid and certain routine control analyses of both the raw ores and the finished product, particularly where the physical properties of the product are greatly affected by the inclusion of small amounts of impurities. WHB(14)

Rapid Colorimetric Method for Determination of Molybdenum in Plain Carbon and Alloy Steels. THOS R. CUNNINGHAM & H. L. HAMMER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 106–107.

An accurate colorimetric method for the determination of Mo in the presence of Ni, Cr, W and other elements, is given. It is best adapted to steels containing a maximum of 1% Mo. MEH(14)

Effect of Manganese and Aluminum Content of Steel on the Determination of Oxygen, Nitrogen and Hydrogen according to the Hot Extraction Method. (Ueber den Einfluss des Mangan- und Aluminiumgehaltes von Stahl auf die Sauerstoff-, Stickstoff- und Wasserstoff-Bestimmung nach dem Heissextraktionsverfahren.) W. EILENDER & H. DIERGARTEN. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 587–591; *Stahl und Eisen*, Vol. 51, July 23, 1931, pages 944–945.

Report 81 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. In using the apparatus described and in observing temperatures between 1550° and 1600° C. for aluminum bearing steels, there are no difficulties in determining O, N and H in steels containing less than 0.2% Al and 0.6% Mn. Within this concentration range, the values of O, N and H obtained are not remarkably affected. GN(14)

On the Electrolytic Deposition of Traces of Metals and Their Identification by Spectrographic Analysis. (Sur le dépot électrolytique de traces métalliques et leur carcartérisation par l'analyse spectrale.) E. BAYLE & L. AMY. *Bulletin Société Chimie*, France, Vol. 43, 1928, pages 604–624.

Working details are given for the deposition of traces of many of the common metals by electrolysis of appropriate solutions between a Pt anode and a Zn or Cu cathode. The limiting concentrations at which the metals can be deposited on a Cu cathode are as follows: Au 10^{-6}, Ag 10^{-5}, Pb 10^{-10}, Sb 10^{-4}, Co 10^{-5}, Ni 10^{-7}, Fe 10^{-7}, Cu 10^{-8}, Mn 10^{-10}, Zn 10^{-8}. On a Zn cathode Cu may be deposited from concentrations as low as 10^{-7} and Ag 10^{-6}. The original must be consulted for operating details and for the technique used in the spectrographic work. It is stated that rough quantitative results may be obtained by observing in the spectrograph the number and intensity of the lines of the trace of metal deposited. Ha(14)

Quantitative Determination and Separation of Lead and Bismuth by the Volumetric Filtration Method. (Ueber die quantitative Bestimmung und Trennung von Blei und Wismut mittels der Filtrationsmethode.) HANS TH. BUCHERER & F. W. MEIER. *Zeitschrift für analytische Chemie*, Vol. 83, 1931, pages 351–361.

The authors have shown the advantages of carrying out quantitative precipitations with measurement of the volume of reagent required to effect complete precipitation as detected by filtering the solution and testing with more reagent and also with a solution containing the ion to be precipitated. For determining Pb, precipitation as $PbSO_4$, as $Pb_3(PO_4)_2$, as $PbCrO_4$ and as $PbSeO_3$ was tested, and the last 2 methods proved suitable for this kind of analysis. For precipitation of Bi, a 0.015–0.02 *N* solution of H_2SeO_3 is suitable. The Bi-selenite is formed in 0.05–0.08 *N* HNO_3 solution but HNO_3 prevents the precipitation of the corresponding Pb salt. For the determination of Bi and Pb, therefore, make the solution 0.05–0.08 *N* in HNO_3 (0.15 g. Bi or less) and the volume of solution about 100 cc. Heat to 70° and add the H_2SeO_3 solution with shaking. Toward the end of the reaction, heat to boiling. After the determination of the Bi, add an excess of NaOAc, heat to 80–90° and precipitate the Pb (0.1 g. or less) with the same H_2SeO_3 solution or with $K_2Cr_2O_7$ solution. The results obtained in 8 analyses all agreed within 0.23 mg. (1.5% of the Pb content). 18 references. Ha(14)

Method for the Determination of Nitrogen in Steel and Iron Alloys. (Verfahren zur Bestimmung des Stickstoffs in Stahl und Eisenlegierungen.) P. KLINGER. *Archiv für Eisenhüttenwesen*, Vol. 5, July 1931, pages 29–33.

Report 82 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The paper critically surveys the methods which have been used up to the present time for the determination of N in steel and its alloys and the causes and reasons which cause a failure of the common solution method are noted. A new apparatus and method which makes it possible to determine the total amount of N in steel samples, independent of their solubility in acids have been developed and are described. GN(14)

The Estimation of Nickel in Cast Iron. H. W. KEEBLE. *Iron & Steel Industry & British Foundryman*, Vol. 4, Sept. 1931, pages 389–390.

Two methods of analysis are given; one to be used when Ni alone is determined, the other when the analyses of all elements are made. KCN in excess is added to a solution containing Ni. The excess is determined with $AgNO_3$ using KI as indicator. Repeated analyses agree within 0.02%. CHL(14)

Modern Organic Reagents used for the Detection and Determination of Metals. JULIUS GRANT. *Industrial Chemist*, Vol. 7, May 1931, pages 197–200; June 1931, pages 227–230.

In the first part a bibliography of 18 references is given. Methods employed in the use of organic reagents are (1) the use of selective precipitants for certain metals, (2) the use of reagents providing very sensitive and highly selective color tests for small traces of certain metals, (3) methods employing organic titrating reagents and (4) methods employing organic indicators. Gravimetric precipitation reagents discussed are dimethyl glyoxime, salts of xanthic acid, cupferron or copperon, pyridine thiocyanate, quinoline derivatives, cinchonine hydrochloride, etc. In the second part 30 references are given. The reagents are discussed as (1) solvents, (2) colorimetric reagents, (3) volumetric reagents and (4) indicators. The former is often auxiliary to the others. Among the colorimetric reagents briefly discussed are cupferron, Alack's "Alizarin Red S.," pyridine potassium iodide, etc. Among the indicators are the dyes used in acid-alkali titrations, organic indicators used to show the end point in oxidation reduction titrations, and finally, the turbidity, fluorescent and absorption indicators. RAW(14)

The Determination of Moisture in Bituminous Coals and Lignites. (Die Bestimmung der Feuchtigkeit in Stein- und Braunkohlen.) C. HOLTHAUS. *Archiv für Eisenhüttenwesen*, Vol. 5, Sept. 1931, pages 149–162.

Report 86 of the Chemical Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The following determination methods were checked in co-operation with several German steel mill laboratories. (1) Xylol method according to Erdmann. (2) Drying in drying oven at 105° C. (3) Drying in vacuum according to Thlow. (4) Drying at 105° C. and accumulating the water in a medium of absorption. (5) Method according to Kubierschky. (6) Method according to Dolch and Strube. (7) Method according to Zerewitinoff (8) Technical water determination by drying a large sample at 105° C. over night. The results are as follows: (1) The xylol method gives values within the admissible limits of error for any content of water practically to be found in bituminous coals and lignites. The advantage of the method is the direct measuring of the water and, therefore, is suited to determine the true water content of solid fuels. (2) Drying at 105° in drying ovens gives no correct values. It was proven that coals adsorb air during heating and cooling. Furthermore, according to the type of coal oxidation and giving off of volatile hydrocarbons takes place. (3) Drying in vacuum gives the best values of all indirect methods by determining the loss of weight. (4) Although the method gives reliable results, the method cannot be recommended due to its complicated procedure. (5) The Kubierschky method is applicable to coals of a high content of water. (6) The Dolch and Strube method gives results which are in accordance with the xylol method. The method has the advantage of performance in a shorter time. (7) The Zerewitinoff method does not give reliable results. (8) The common method of the practice of drying a sample at 105° C. over night fulfills all requirements. GN(14)

Modified Ford-Williams Method. D. H. JAMES. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 31–32.

The proposed method is applicable to the determination of Mn in high Cr-Ni alloys which are practically insoluble in nitric acid. MEH(14)

Determination of Copper in Dairy Products. H. T. GEBHARDT & H. H. SOMMER. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 24–26.

A new method for the determination of Cu in foodstuffs and biological material has been devised. The method of Elvehjem and Lindow is shortened considerably, the separation of copper sulphide improved and the danger of losses in transfers minimized, by shaking out the precipitated copper sulphide with chloroform instead of separating it by filtering. The ashing temperature should not exceed 565° C. and the time of ashing should be from 3 to 4 hours. Detailed directions are given. 9 references. MEH(14)

Method for Electrolytic Extraction of MnO, MnS, FeS and SiO_2 Inclusions from Plain Carbon Steels. G. R. FITTERER. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 440, Sept. 1931, 15 pages.

Sufficient details are given for the installation of the equipment and for analyzing the residues. The method and results will be fully described in a Bureau of Mines paper now being prepared. Contains 2 references. JLG(14)

Study of Nitrogen in Steels. (Étude de l'azote dans les aciers.) B. GETZOV. *Chimie & Industrie*, Vol. 25, Special Number, Mar. 1931, pages 458–463.

Previous work on the form in which N is present in steel and its effects on the properties of steel are briefly reviewed. Steel parts which had failed in service and which had practically the same composition (P, Mn, C, S, Si) as others which had proved satisfactory, were found to have a much higher N content (about 50–100% higher) than the latter, which proves the great influence of N on the brittleness, hardness and elongation of steel. The author has devised a method (accurate to the 4th decimal place) for determining N in steels consisting essentially in dissolving 10 g. in 50 cc. HCl (d. 1.19), adding 50–75 cc. H_2O, transferring to a 1 liter flask, adding granular Zn and 200 cc. of 15% NaOH, distilling through a Sn condenser into 0.01 *N* H_2SO_4, and titrating with 0.01 *N* NaOH in presence of methyl orange as indicator. The technic of the method is described in detail. WHB(14)

The Analysis of Nickel-Bronze. J. R. GORDON (Ontario Research Foundation). *Canadian Chemistry & Metallurgy*, Vol. 15, Sept. 1931, pages 252–253.

Ordinary methods for bronze analysis have not proven entirely satisfactory when applied to Ni-bronzes. Methods have been adopted whereby a single sample suffices for determining Pb, Cu, Sn, Fe and Ni. Pb is determined as $PbSO_4$, Cu electrolytically with rotating anodes and Ta gauze cathodes, Sn is precipitated as sulphide and weighed as SnO_2, the Ni precipitated with dimethylglyoxime, after oxidation of the Fe by $(NH_4)_2S_2O_8$ and precipitation as hydroxide. HISTORICAL & BIOGRAPHICAL (15)

Structural and Ornamental Iron Casting in the Last 50 Years. (Der Bau- und Ornament-Eisenguss in den letzten fünfzig Jahren.) TH. EHRHARDT. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Aug. 14, 1931, pages 649–653; Aug. 21, 1931, pages 667–672.

A thorough historical development of styles and types in cast iron ornaments with numerous photographs to illustrate columns, stairs, church decorations, etc. Economical as well as mechanical reasons for changes in styles are discussed. Ha(15)

An Investigation of the Microstructures of Fifteen Silver Greek Coins (500-300 B.C.) and Some Forgeries. C. F. ELAM. *Journal Institute of Metals*, Vol. 45, No. 1, 1931, pages 57–69 (with discussion); abstracted in *Engineer*, Vol. 151, Mar. 20, 1931, pages 327–328; *Engineering*, Vol. 131, Mar. 13, 1931, page 366.

Paper read before the Institute of Metals, Mar. 11, 1931. See *Metals & Alloys*, Vol. 2 Aug. 1931, page 148. LFM(15)

Working Methods of Ancient Coin Manufacture, Especially Counterfeit Coins. (Die Arbeitsmethoden der antiken Münztechnik, insbesondere der Falschmünzerei.) O. DAHL. *Metallwirtschaft*, Vol. 10, Aug. 21, 1931, pages 659–663.

Examination of ancient coins discloses that they were made either by casting in stone or clay or by pressing in bronze or iron dies. Greek coins were all pressed while the larger Roman coins were cast. The counterfeit coins consisted of copper centers with a coating of silver, instead of solid silver. One Roman and two Greek coins were given a thorough microscopic examination. In the Greek coins, the Ag covering was 0.18 mm. thick; in the Roman, only 0.04 mm. In the Greek coins, the center consisted of a cast Cu slug which was placed between two pieces of sheet Ag which overlapped at the edges. This was then heated and pressed in the die. At some points, Cu-Ag solid solution was formed between the pure Cu and pure Ag, at others the heat was high enough to form Ag-Cu eutectic. The structure of the pure Cu and pure Ag sections shows that the temperature was high enough to recrystallize the Cu and Ag, over 780° C. In no case was any solder discovered. In the Roman coin, the covering consisted entirely of Cu-Ag alloy. This could be due to a higher alloying temperature or to the use of a Ag covering alloyed with Cu instead of pure Ag. A reproduction of a coin by the Greek process was attempted and microscopic examination proved that it had the same structure. CEM(15)

The Evolution of Malleable Cast Iron in France. RAYMOND GAILLY. *Foundry Trade Journal*, Vol. 43, Oct. 9, 1930, pages 255, 256.

Abstract of paper read at the Pan-European Foundry Congress at Liege. Chiefly an historical review. In 1922, two 10-ton reverberatory furnaces were installed in France. Later on, the manufacture of black-heart in the cupola was started; on a test bar, this gave a strength of about 20.3 tons/in.^{2} and 8% elongation. In 1926–27, the reverberatory furnaces were modified, enlarged and changed to use pulverized fuel. Annealing furnaces followed a similar evolution. Transformation of melting methods and improvement of annealing control gave to malleable Fe homogeneity and regularity. Ni and NiCr additions are considered and physical properties of plain and Ni bearing malleable Fe are compared. VSP(15)

G. Tammann's Publications on the Chemical Properties of Metals and Alloys. (Arbeiten von G. Tammann über die chemische Eigenschaften von Metallen und Legierungen.) W. KÖSTER. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 142–146.

The fourth article concluding a set of historical reviews of Tammann's research work on the occasion of his 70th birthday celebration covers the following points: the chemical attack and its limitation, the n/8 law, atomistic interpretation and the colored surface films. EF(15)

Friction Bearing in the Last Five Years. (Das Gleitlager im letzten Jahrfünft.) S. KIESSKALT. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Aug. 8, 1931, pages 1025–1026.

An historical review of development of this type of bearing in the past 5 years. This development has taken place mainly in the direction of lubricants and the methods of classifying them. With regard to design, it now recognized that lubricating grooves in the surface should always be avoided. Ha(15)

Crystallization and Melting. A Valuation of G. Tammann's Work on the Nature of the Solid State. (Kristallisieren und Schmelzen. Eine Würdigung der Arbeiten von G. Tammann über das Wesen des festen Zustandes.) FR. KÖRBER. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 134–137.

An historical review of G. Tammann's contribution to the problems involved in melting and crystallizing and the significance of his findings with reference to metallurgy. EF(15)

Technical Organization of Metallurgical Establishments. (Sull'organizzazione tecnica degli stabilimente siderurgici.) A. CARLI. *La metallurgia Italiana*, Vol. 23, June 1931, pages 485–499.

Comments on the control, measurement and recording of every factor involved in heating processes in a metallurgical plant, in order to reduce cost of production. HWG(16)

Wire Mill Management. E. G. BROWN. *Wire & Wire Products*, Vol. 6, Aug. 1931, pages 325–327.

An efficient organization, plant investment and goods inventory are described and the results obtained in one case are cited. Ha(16)

General View of Coal Industry and Coking Plant Organization in the United States. (Vue d'ensemble sur l'industrie houillere et l'organisation des cokeries aux États-Units.) CH. BERTHELOT. *Revue de Métallurgie*, Vol. 28, July 1931, pages 391–404.

On account of its high quality, only 6.7% of total coal production in the U. S. is concentrated, and 85% of this by wet methods. The general trend of coking plant construction is to reduce to a minimum the first cost of the installation without affecting in any way its efficiency. In small plants, like that at Sterling, Ill., continuous vertical regenerator ovens are used, in larger ones Becker ovens predominate. By using a definite ratio between lumps and fines, rapidly heating the charge after introduction and introducing a quenching chamber at the exit, hangovers are entirely prevented and a remarkable efficiency is obtained at Sterling. Becker ovens have an efficiency about 5 times greater than French installations made before 1926 on account of using silica brick permitting a much higher temperature and simplicity of design of the gas passages. Most of them are being heated by blast furnace gas. Close grading of coal by size is strictly observed. "Pennsylvania crusher" installations observed appear to be decidedly better than any European plant of the same type. Surface condensers for tar removal always used in Europe are replaced here with scrubbers followed by Cottrells while ammonia liquor from the former passes through tubular coolers. Perfect cleaning and continuous operation prevail, the shutdowns occuring only once in 2 years or so instead of one every 2 months as in Europe. The layout of sulphate plants is much better, uniting many installations under the same roof with a great efficiency rather than locating them in different buildings as in continental practice. Thermal control is remarkably good. JDG(16)

Electrochemical and Electrometallurgical Industries of Norway. (Les industries electrochimiques et electrometallurgiques de la Norvege.) KNUDSEN. *Journal du Four Electrique*, Vol. 40, June 1931, pages 210–211.

Abundance of water power led Norway to a rapid expansion of industries requiring it. At present more than 120,000 horse power are developed of which more than 80,000 are used in electrometallurgical plants. An historical sketch of the development is given. JDG(16)

Bauxite and Aluminum in 1929. C. E. JULIHN. *Mineral Resources of the United States*, 1929, Part 1, May 20, 1931, pages 485–506, *United States Bureau of Mines.*

Al was produced in 1929 in only North America and Europe; 132,000 metric tons by the former and 129,900 by the latter, a total increase of about 8% over 1928. The U. S. produced 38.98%, Germany 12.03%, Canada 11.42%, France 11.07%, Norway 10.39%, Switzerland 8.40% and England, Italy, Austria and Spain together 7.71%. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Utah in 1929. C. N. GERRY. *Mineral Resources of the United States*, 1929, Part 1, June 12, 1931, pages 581–635, *United States Bureau of Mines.*

The output in 1929 of Au, Ag, Cu, Pb and Zn from Utah mines increased 21% over 1928 to a value of $95,985,201. Au output increased 13%, Ag 3% in quantity (decrease in value), Cu 9% in quantity and 33% in value, Pb 2% in quantity, and 10% in value, and Zn 9% in quantity and 16% in value. Utah was the leading Ag producer, second for Cu and Pb and fifth in Zn. AHE(16)

Gold, Silver, Copper, Lead, and Zinc in Montana in 1929. C. N. GERRY & T. H. MILLER. *Mineral Resources of the United States*, 1929, Part 1, pages 831–876, July 27, 1931, *United States Bureau of Mines.*

The mine production of Au, Ag, Cu, Pb and Zn in Montana in 1929 was $71,779,547, nearly 30% increase over 1928, largely due to the increase in Cu output from 248,262,027 lb. ($35,749,732) to 297,725,973 lb. ($52,399,771). There were also increases in the output of Ag (17%) and Pb (16%), but decreases in Au (6%) and Zn (18%), the latter more than 29,000,000 lb. Production of Au was 54,758.03 oz., Ag 12,716,977 oz., Pb 39,213,707 lb. and Zn 136,351,734 lb. The state ranked 2nd in Ag production, 3rd in Cu and 4th in Zn. AHE(16)

Iron Ore Mining in Chile and Prospects of a Native Steel Industry. (Der Eisenerzbergbau in Chile und Aussichten einer heimischen Eisenhüttenindustrie.) C. H. FRITZSCHE. *Stahl und Eisen*, Vol. 51, Apr. 30, 1931, pages 541–547.

Report No. 26, of the Committee on Ores of the Verein deutscher Eisenhüttenleute. Chile possesses 2 large iron ore deposits in the desert of Atacama, Algarrobo and Tofo, beside some medium deposits and numerous small deposits which cannot be considered for mining economically. At present, mining by the Bethlehem Steel Company takes place only at Tofo, with a yearly output of about $1^1/_2$ million tons of ore. Approximately $1^1/_3$ million tons of coal are mined in Middle Chile. This coal can be successfully coked in high temperature silica coke ovens. Furthermore, large amounts of charcoal are available; charcoal production, however, is expensive because of the difficult transportation and the high percentage of waste in the raw wood. Large water powers are available all over the country. The steel consumption of Chile amounts approximately to 150,000–200,000 tons/yr. In spite of the premium paid by the government of Chile for the home production of steel (35 M/ton), the project of the building of a steel industry has not yet materialized. The most comprehensive project is the construction of a plant in the Valdivia district which was intended to utilize the power of the Huilo-Huilo River. Although this project has been abandoned, new projects have been made. The cokeability of the Chile coal will play an important role in these projects. GN(16)

Gold, Silver, Copper and Lead in Texas in 1929. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1929, Part 1, pages 761–764, July 23, 1931, *United States Bureau of Mines.*

The gross value of Au, Ag, Cu and Pb produced in Texas in 1929 was $683,920, a decrease from $899,204 in 1928. Au output increased from $10,115 to $26,439 and Pb from 695,570 lb. to 849,683 lb. Ag decreased from 1,340,622 to 1,020,5 16 oz. and Cu from 447,792 to 341,000 lb. AHE(16)

Gold, Silver, Copper, Lead and Zinc in New Mexico in 1929. CHAS. W. HENDERSON. *Mineral Resources of the United States*, 1929, Part 1, pages 729–759, July 23, 1931, *United States Bureau of Mines.*

The gross value of the recoverable Au, Ag, Cu Pb and Zn from the 121 producing mines of New Mexico in 1929 was $24,473,675, an increase of 30% over 1928. Output of all the metals increased in amount and value. Production was: Au 35,176.46 oz., Ag 1,121,546 oz., Cu 97,717,262 lb., Pb 22,260,811 lb. and Zn 68,910,000 lb. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Nevada in 1929. V. C. HEIKES. *Mineral Resources of the United States*, 1929, Part 1, July 3 1931, pages 637–673, *United States Bureau of Mines.*

In 1929 the total value of mine production of Au, Ag, Cu, Pb and Zn in Nevada was $33,030,237 or 6% more than in 1928. The quantity and value of Au (6.5%) and Ag (10 and 18%) decreased; the quantity of Cu decreased 12%, but the value increased 8%; and the quantity and value of both Pb (25 and 35%) and Zn (150 and 170%) showed substantial increase over 1928. Outputs were: Au 163,711.22 oz., Ag 4,923,526 oz. Cu 140,138,809 lb. Pb 19,692,568 lb. and Zn 16,920,083 lb. AHE(16)

The Potentialities of South American Markets of Cast-Iron Pipes. R. E. FLINN. *Foundry Trade Journal*, Vol. 45, Aug. 20, 1931, page 118.

A brief summary of business prospects in the more important South American countries. Reference is made to the fact that during 1928 and 1929, only 2 of the South American republics (the Argentine and Uruguay) purchased cast iron pipes from the United Kingdom in any considerable quantity. OWE(16)

Use of Electron Metal Spreads Rapidly in Europe. PAUL FIDRMUC. *Canadian Foundryman*, Vol. 22, July 1931, page 17.

A brief statement, accompanied by 2 photographs, regarding the increasing use of the magnesium-base alloy "Electron," the annual production of which in Germany reaches approximately 6000 tons. OWE(16)

Saving in Costs from New Plant Arrangement. BURNHAM FINNEY. *Iron Age*, Vol. 128, August 6, 1931, pages 366–369.

Describes rearrangement of production facilities and installation of new equipment at the plant of Dodge Brothers, Inc., Detroit. Efficiency in manufacturing trucks has increased 30%. Relocation of final assembly line has saved 60% in handling parts VSP(16)

Rationalization. (Rationelles Arbeiten.) GEISSEL. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 13, 1931, pages 137–142.

Several methods and molding machines are discussed with the object of economizing and rationalizing the molding process. Diagrammatic sketches show the individual stages of molding a piece for quantity production and methods are suggested for supervising the production. Ha(16)

PLANTS & LABORATORIES (17)

North German Refinery. (Norddeutsche Raffinerie.) E. VAN ERCKELENS. *Engineering & Mining Review*, Vol. 132, Aug. 24, 1931, pages 160–164.

Electrolytic Cu, Pb, Ag, Au, Sb, Ni and Cd are the chief products of the refinery. Several illustrations are included, with the description of plant operations. WHB(17)

The Electrical Plant of the Erftwerk A. G. (Die elektrischen Anlagen der Erftwerk A. G.) DUNKER. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July–Aug. 1931, pages 293–295.

The electrical energy for the electrolysis of Al is supplied under 100,000 V. and reduced, in 2 transformers of 30,000 kva. each, to 5,000 V. They have Al windings. The necessary direct current is generated in 15 motor-generator-sets of 3780 kw. each at 250–270 V. Al is extensively used for cables, bus bars, etc. The transformers with Al windings have not had any failure in the 13 yrs. of their operation. Ha(17)

Weighing and Counting Devices for Materials Handling. A. B. JACOBUS. *Iron Age*, Vol. 127, Apr. 9, 1931, pages 1154–1157.

Abstract of paper read at Cleveland before the American Society of Mechanical Engineers. Gives a number of illustrations, together with brief descriptions of appliances such as cupola charging scales, hopper batching scales, scales for weighing hot metal and railroad tracks, etc. VSP(18)

Pulverized Coal Experiences in a Malleable Iron Foundry. C. F. HERRINGTON. *Iron Age*, Vol. 127, June 11, 1931, pages 1896–1901.

Describes the pulverized coal installation for the Erie Malleable Iron Co., Erie, Pa., that has been in operation since 1924. The erection and placing in operation was done by Heyl and Patterson, Inc., Pittsburgh, Pa. VSP(18)

Correct Power Application in Pressed Steel Plants. O. H. HENSCHEL. *Metal Stampings*, Vol. 3, Sept. 1930, pages 821–824, 832; Oct. 1930, pages 905–908.

Discusses installation of motors for driving presses, to reduce power consumption and improve power factor. Deals with the economic effects and savings resulting therefrom. MS(18)

Electrical Drive of Band-Conveyor Installations. (Elektrischer Antrieb von Band-Förderanlagen.) W. HERBECK. *A. E. G.-Mitteilungen*, Sept. 1931, pages 549–552.

Description of the electrical installation for conveying of 260–300 tons lignite/hr. over a distance of about 570 ft. at a grade of 20 degrees. Ha(18)

Electrical Equipment of a Reversible Blooming Mill in the Steel Plant Esch on the Alz of the Société des Aciéries Réunis de Burbach-Eich-Dudelange. (Equipement électrique d'un blooming reversible installé aux usines d'Esch-s.Alz de la Société des Acieries Réunis de Burbach-Eich-Dudelange.) M. BOUTON. *Revue Technique Luxembourgeoise*, Vol. 23, Mar.-Apr. 1931, pages 49–61.

This mill is for rolling steel ingots of 5 tons; its hourly capacity is 100 tons. In 23–25 passes, the ingot is rolled to sheets. The electrical equipment consists of a reversible d.c. motor of 8000 HP continuous at 59–140 r. p. m. and a maximum torque of 280 meter-tons; maximum output, 23,000 HP at 59 r. p. m. It is supplied by an Ilgner motor-generator-set consisting of an asynchronous 3-phase motor, 3000 volts, 42.5 periods, 4500 HP, driving 2 DC generators each of 3375 KW, 625 volts, 500 r. p. m. or 2700 KW, 500 volts, 400 r. p. m. The maximum output is 10,000 KW. The flywheel runs with a peripheral speed of 117.5 m./sec. and has a flywheel effect of 540 tonmeter.[2] It works with 20% speed drop. The starting machine, excitor group, control boards, diagram of connections and operation is described in detail. Ha(18)

MISCELLANEOUS (20)

Building Reliability Into the Pressure Vessel. F. O. LEITZELL. *Chemical & Metallurgical Engineering*, Vol. 37, Sept. 1930, pages 566–567.
Factors which must be considered in design of pressure vessels are safety, simplicity, expansion and contraction, metal composition and ease of fabrication, safety in operation being the prime requisite. Adequate testing is imperative. MS(20)

Scrap Control in Implement Manufacture. GEO. LAIDLER. *Canadian Foundryman*, Vol. 22, July 1931, pages 14–16.
A description of the organized procedure followed by one firm in its endeavor to control the wastage of iron and steel in the manufacture of agricultural implements. The article is accompanied by a diagram which might be described as a flow sheet of the various materials entering the works. OWE(20)

Caution in the Changing of Cleaning Agents of Acetylene-Generators. (Vorsicht beim Auswechseln der Azetylenentwickler.) FREYTAG. *Oberflächentechnik*, Vol. 8, Sept. 1, 1931, page 189.
Two very grave accidents occurred in a locomotive factory where the workmen were exchanging the cleaning agents in acetylene generators. Both suffered a complete paralysis of the sensorial system of the face and mouth. This was attributed to poisonous vapors rising from the cleaning mass which had not been changed early enough. Both cases seem incurable. Ha(20)

Progress in Coking Practice in 1930. (Fortschritte im Kokereiwesen in Jahre 1930.) W. HECKEL. *Stahl und Eisen*, Vol. 51, June 25, 1931, page 794.
The author briefly reviews 11 different important papers dealing with the recent progress in coking practice. GN(20)

The Magnetization of Permanent Magnets with a High Current Dynamo. (Das Magnetisieren permanenter Magnete mittels Hochstromdynamo.) R. A. HAMANN. *Automobiltechnische Zeitschrift*, Vol. 34, Sept. 10, 1931, pages 559–560.
A detailed calculation of an electromagnet fed by a dynamo for the magnetization of permanent magnets. Ha(20)

Empirical Control of a Simple Equation for Actual Gases. (Empirische Kontrolle einer Gleichung für reale Gase.) E. J. M. HONIGMANN. *Forschung auf dem Gebeite des Ingenieurwesens*, Vol. 2, July 1931, pages 261–266.
The actual gas equation is defined. The determination of its value for various materials by means of tests and tables is explained. MAB(20)

Conservation Through Baling Bulky Scrap. HENRY JACOBSON. *Iron Age*, Vol. 128, Aug. 6, 1931, pages 374–375.
Sheet scrap baling can be divided into 3 groups: (1) sheet and tin plate mills which bale trimmings from sheets they manufacture; (2) manufacturing plants producing stampings; and (3) scrap yards, which bale accumulation of new scrap. The value of scrap lies in the conservation of Fe ore. VSP(20)

Recovery of Tin-Bearing Wastes. V. FROELICHER. *Textile World*, Vol. 80, Sept. 19, 1931, page 35.
The Sn contained in the water used for washing weighted silks is recovered in modern plants by neutralizing the Sn-bearing wastes by the addition of a milk of lime slurry, continuously added from an agitating tank controlled by routine chemical analysis of the final discharge to the river. The rate of flow of the Sn-bearing water is about 1600 gal./min. It contains about 90 mg./liter of Sn salts with a value of $150.00/day. These figures are from the recovery plant of the Hawthorne Works of Textile Dyeing and Printing. Ha(20)

The Running Properties of Light Metal on Nitrided Steel. (Ueber die Laufeigenschaften von Leichmetall auf Nitrierstahl.) LEON GUILLET. *Automobiltechnische Zeitschrift*, Vol. 34, Aug. 20, 1931, pages 528–529; *Genie Civil*, Vol. 51, 1931, pages 489–495.
Experiments made with piston rods of the Al alloy, "Alugir" of the composition Cu, 3.5–4%; Ni, 0.5–0.9%; Mg, 0.5–1%; Si,0.3–0.75% are described. These rods were running without a bearing metal directly on the crankshaft and piston pin. Since the light metal has about twice the expansion coefficient of steel, very careful measurements of the holes and diameters of the individual parts were made at different temperatures from −10° to +150° C. In spite of the comparatively great differences, no practical difficulties were encountered; this is very likely due to the better heat conductivity of the piston rod which remains colder and expands less. The saving in weight and mass in the piston rod is considerable, although the section has to be larger. Ha(20)

The Development of an Electron Emitting Alloy. O. S. DUFFENDACK, R. A. WOLFE & D. W. RANDOLPH. *Metal Industry*, London, Vol. 38, May 22, 1931, pages 527–528.
Extended abstract of paper presented before the Electrochemical Society, April 1931. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 186. PRK(20)

Electrically Driven Rollers and Their Application. (Die Elektrorollen und ihre Anwendung.) W. ALBRECHT. *Stahl und Eisen*, Vol. 51, July 23, 1931, pages 929–935.
Report 86 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The article discusses the advantages and disadvantages of electrically driven rollers for various purposes, with special reference to new types of roller constructions as they are applied in rolling mills for the transportation of rolled material. GN(20)

The Superintendent's Point of View. J. R. BAUSCH. *Steel Founder*, Vol. 1, Nov. 1930, pages 14–15.
Relation between selling of steel casting and quality production; need of rigid inspection method. Ha(20)

A Noble Profession: Makers of Copper Boilers. (Une profession d'élite: La chaudronnerie en cuivre.) G. DUBOIS. *Cuivre et Laiton*, Vol. 4, Aug. 30, 1931, pages 379–382.
The importance of coppersmiths in former times is pointed out in a brief historical sketch. Belgium and Germany are especially referred to. The author advocates the extension of this art, especially to light metals now so widely used, notwithstanding the competition of steel. Ha(20)

Novel Pattern Methods Devised to Make Decorative Castings. JAMES BREAKEY. *Canadian Foundryman*, Vol. 22, July 1931, pages 7–9.
A description of some of the architectural metal work which is being produced at the foundries of the Architectural Bronze and Iron Co., Toronto, Ontario. The article is accompanied by 4 photographs. OWE(20)

Development and Installation of the Hawkesworth Detachable Bit. CHAUNCEY L. BERRIEN. *Transactions American Institute of Mining & Metallurgical Engineers*, 1930, pages 139–167.
Includes discussion. See *Metals & Alloys*, Vol. 1, May 1930, page 527. (20)

Related Class-Room Training for Foundry Apprentices. S. M. BRAH. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Sept. 1931, pages 312–335.
A survey of related instruction given foundry apprentices in plant and municipally conducted training courses. CHL(20)

USEFUL BOOKS

TIN

C. L. MANTELL — *A. C. S. Monograph No. 51*

353 Pages — Illustrated — $5.25

A comprehensive survey of the various phases of the production of tin from its ores to its commercial application. The history, physical and chemical properties, and the production, distribution, and consumption of the metal have been presented and discussed from the viewpoint of the chemist, the metallurgist, and the chemical engineer rather than from the viewpoint of the mining engineer or the mechanical engineer. Secondary tin and detinning of tin-plate scrap has been treated from the economic as well as from the metallurgical and chemical viewpoint.

BEARING METALS AND BEARINGS

W. M. CORSE — *A. C. S. Monograph No. 53*

383 Pages — Illustrated — $5.25

A survey of the fundamental principles and practices involved in the selection of bearings and bearing metals, together with a bibliography of reference literature from 1900-1928 inclusive.

SHEET STEEL AND TIN PLATE

R. W. SHANNON

285 Pages — Illustrated — $5.00

A practical work on the utilization of sheet steel and tin plate in the steel-fabricating arts. The essential facts concerning sheet steel and tin plate are clearly set forth in everyday language, enabling the layman to gain therefrom an insight into the possibilities and limitations of these important kinds of steel products, which will permit him to understand present day uses better, and possibly to visualize new uses, for these materials.

METALLOGRAPHY

GUSTAVE TAMMANN

Translated from the Third German Edition
By Reginald S. Dean and Leslie A. Swenson

388 Pages — Illustrated — $7.00

A textbook. A translation of the leading German treatise on this subject covering most completely the chemistry and physics of metals and their alloys. The author has involved a system of metallographic theory which is distinct from that of any other school of metallurgists.

The CHEMICAL CATALOG CO., *Inc.*
419 FOURTH AVENUE NEW YORK, U. S. A.

FOUNDRY PRACTICE & APPLIANCES (22)

Cheap Melting: The Merits of Modern Crucible Furnaces. G. S. WATSON. *Foundry Trade Journal*, Vol. 45, July 23, 1931, page 58.

A short article dealing with progress lately made in designs of crucible and open-flame furnaces, emphasizing the value of the former type of equipment from the viewpoint of flexibility and economy. OWE(22)

The Use of Refined Metals in the Foundry. D. R. TULLIS. *Foundry Trade Journal*, Vol. 44, May 7, 1931, pages 321–326, 328.

An article dealing with the chlorine refining process which involves the use of boron trichloride. The use of this refining material in connection with the manufacture of aluminum castings is discussed, the article being accompanied by 32 photographs showing, among other things, the changes in structure produced by modification as a result of the refining process. OWE(22)

To Hold Casting Boxes Down or to Clamp Them in Machine-Molding. (Kasten beschweren oder Kastenklammern in der Maschinenformerei.) H. TILLMANN. *Die Giesserei mit Gieserei-Zeitung*, Vol. 18, Jan. 9, 1931, pages 37–39.

The clamping together of casting boxes instead of loading them down can often relieve the workman of much additional heavy work. A few clamping methods are described. Ha(22)

Eliminating the Shell Defect in Ingot Molds. D. J. THOMAS. *Iron Age*, Vol. 128, July 30, 1931, pages 310–311.

Shell defect in ingot molds is a serious matter which demands constant care. The shell will be found to run the entire length of mold and situated always in the 4 angles. It never appears on flat surfaces of the mold. Serious trouble comes from defect when shell is found deeply embedded in 4 angles. Shell is due to segregation of phosphide eutectic. Rapid corner cooling for ingot molds is advocated to avoid shell defects. Emphasizes importance of using suitable sand. VSP(22)

Recent Investigations on Quality of Piston Rings in Relation to Manufacturing Process. (Neue Untersuchungen über den Gütgrad von Kolbenringen in Abhängigkeit vom Herstellungsverfahren.) N. STERN. *Automobiltechnische Zeitschrift*, Vol. 34, Feb. 16, 1931, pages 89–93.

Recent investigations on quality of piston rings in relation to casting method revealed that, although beyond certain limit of rings in single ring casting, the pot casting method is connected with less expense, nevertheless the latter yields a product of lower quality. According to the author's data, the tensile strength of single cast ring is about double that in ring cut out from bushing and bending strength 50% higher. By aid of micrographs shown in the paper, the author attributes the higher quality of singly cast ring to finer distribution of graphite and uniform structure throughout the cross section. Centrifugal casting may confer similar structure to piston ring, however, because, owing to the non-uniform rate of solidifying, the internal strains are set up. Various testing methods for roundness and distribution of stresses are discussed. ER(22)

X-Ray as Production Tool to Improve Quality of Aluminum Alloy Castings. E. M. GINGERICH & H. J. ROWE. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Aug. 1931, pages 174–196.

Detection of blow holes, porous spots and shrinkage are of value in improving methods of gating, feeding and pouring. Experience is necessary to properly interpret X-ray data. CHL(22)

Economy in the Operation of a Foundry. (Sparsame Wirtschaft im Giessereibetrieb.) FREYTAG. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Jan. 30, 1931, pages 93–94; Apr. 3, 1931, page 282; May 15, 1931, pages 408–409.

Patterns for a group of castings can often be replaced advantageously by templates and core boxes. The castings made in this manner differ less in dimensions than those made in molds from patterns. Examples of 2 molds—one from a pattern and one made with a template and cores—are used to illustrate the manner in which savings can frequently be realized by using the second method. Suggestions are given as to the manner of avoiding hollow spaces at the joint of core-parts so that no burner or seam is formed which must be removed by a time-consuming process, later. Ha(22)

A Method for Molding a Rope Pulley. ARTHUR GREENHALGH. *Foundry Trade Journal*, Vol. 45, July 30, 1931, page 70; *Canadian Foundryman*, Vol. 22, Aug. 1931, pages 17, 22.

An article accompanied by 2 diagrams, in which a method is described of making a rope pulley by means of which a well-balanced casting can be secured. OWE(22)

Investigation of Core-Binding Materials. (Kernbinderuntersuchung.) K. HUETTENES. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 6, 1931, pages 124–126.

A classification of the materials for binding cores and of the principal requirements which such materials must satisfy is given. Methods of testing cores are discussed. Ha(22)

The Task of the Foundry in the Operation of Steel Plants. (Die Aufgaben der Giesserei im Hüttenbetriebe.) K. HOFFMANN. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 27, 1931, pages 264–266.

The products of an iron works foundry are discussed in the relation they have to their field of application and the equipment required. It is emphasized that for an uninterrupted operation of the plant the foundry is absolutely essential but no other products except those required for the operation of the steel plants should be manufactured. Ha(22)

The Casting of Motor Pistons. (Etwas über das Giessen von Motorkolben.) R. FISCHER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 10, 1931, pages 301–303.

Describes a few novel features in modern manufacture of pistons. They are now usually made as die castings in a metal mold; the exact centering of the core is the subject of several patented arrangements. The material is usually an Al alloy which offers lightness with sufficient strength and low expansion. Several forms of molds are illustrated. Ha(22)

Crucibles for Melting Aluminum. (Kroezen Voor het Smelten van Aluminium.) A. JAESCHKE. *De Gieterij*, Vol. 5, July 1931, page 88.

Graphite crucibles with a binder of neutral loam are used for melting Al. Oxidation is kept down by covering the outside with 2 or 3 layers of waterglass. The adsorption of Si by the melt is minimized by coating the inside with a paste made of molasses and calcined magnesite. HSvK(22)

Experiments with Fuel Oil in the Cupola. J. R. HYDE. *Foundry Trade Journal*, Vol. 44, May 21, 1931, page 354.

Abstract of paper read before the Sheffield Branch of the Institute of British Foundrymen, in which a description is given of experiments made with a cupola of the usual type, fitted with 2 rows of tuyères, 3 in each row, the upper row being 8 in. above the lower. Fuel oil was sprayed into the cupola through the upper tuyères. The charges of coke were reduced by half the usual weight, reliance being placed upon the oil to supply the rest of the heat. Working conditions were modified as shown below:

All coke melting—2 cwts. coke.. 16 cwts. pig and scrap
Oil melting—1 cwt. coke 16 cwts. pig and scrap
6 gals. or 60 lb. oil 16 cwts. pig and scrap

The factors favoring the use of oil were found to be (1) slightly lower S content in the Fé, (2) hotter metal and (3) cleaner and less dump. Disadvantages of the process were, extra air service at 20 lb./in.^{2}, extra cost of fuel, extra trouble to regulate, and waste due to high percentage of CO in the escaping cupola gases. On the whole, there does not appear to be much advantage in the use of oil from an economic point of view. OWE(22)

DETROIT Rocking Electric FURNACES

Small (250 lb.) Detroit Electric Furnace Pouring Heat of Alloy Steel

These furnaces manufactured in capacities from 250 lbs. per hour to 6000 lbs. per hour, offer unusual economy in the production of grey iron, malleable iron, alloy steel, or non-ferrous castings showing the highest possible quality. The rocking action of the

DETROIT ELECTRIC FURNACE

insures complete homogeneity and uniformity, as well as physical characteristics of a highly superior character in the finished castings. Over 50 DETROIT ELECTRIC FURNACES are in use in melting or duplexing grey iron or alloy steel, and over 400 furnaces are in use in the non-ferrous foundries throughout the world.

We will be pleased to send you complete information regarding these remarkable furnaces.

DETROIT ELECTRIC FURNACE COMPANY

827 West Elizabeth St.

DETROIT MICHIGAN

Making of a Cast Iron Funnel with Two Connections in Four Parts with Loam Core. (Herstellung eines gusseisernen Trichters mit zwei Stutzen in vierteiliger Form mit Lehmkern.) R. LOEWER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 22, 1931, pages 422–424.

A few illustrations demonstrate the making of a 4 part mold with templates. The costs of the casting when templates are used are compared with the costs when using patterns and a complete wood pattern. The first method is cheaper. Ha(22)

Mould-handling Methods in Foundries. WILLIAM L. HARTLEY. *Iron & Steel Industry & British Foundryman*, Vol. 4, Aug. 1931, pages 361–365. General. CHL(22)

The Standardization of Core-Boxes of Wood. (Ueber Normung von Kernkasten aus Holz.) F. FREYTAG. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 698–703.

An attempt has been made to develop directions for the manufacture of core-boxes of wood considering kinds of wood, arrangement of the wood in the construction and the dimensions of the core-boxes. Standard core-boxes are illustrated; the outer dimensions have a definite relation to the profiles of the core and to the kind of wood (pine or alder). Ha(22)

New Apparatus for Determination of Moisture in Foundry Sands. (Nouvel appareil pour la détermination de l'humidité des sables de fonderie.) ANDRÉ GUEDRAS. *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Mar. 1931, pages 129–130.

With this apparatus, which was invented by Dr. Toedt, moisture content of foundry sands can be determined in a few seconds. It consists of 2 electrodes and a battery which generates the current. The relative moisture can be determined by hydrolysis through the water of the sand. GTM(22)

Molding and Casting a Foundation Plate. (Het Vormen en Gieten van een Fundatieplaat.) G. L. FRUITHOF. *De Gieterij*, Vol. 4, Nov. 1930, pages 184–187.

Design of a mold with directions for molding and casting a large foundation plate (5 × 3.5 × 1.5 m.). HSvK(22)

Molding Sand. (Over Vormzand.) G. HOFSTEDE KOOPMAN. *De Gieterij*, Vol. 5, July 1931, pages 90–91.

The requirements for good molding sand are briefly indicated. HSvK(22)

Furnaces for Melting Cast Iron, Particularly the Brackelsberg Furnace. (Over ijzersmeltovens, meer in het bijzonder den Brackelsbregoven.) G. HOFSTEDE KOOPMAN. *De Gieterij*, Vol. 5, Jan. 1931, pages 1–6.

Includes discussion. A general description of cupola furnaces and oil-fired furnaces is followed by an outline of the Brackelsberg furnace which uses powdered coal as fuel. This type of furnace, introduced in 1927, is now employed by several German and Dutch foundries. HSvK(22)

Acid-Proof Castings. (Zuurbestending gietwerk.) GUST. KREBS. *De Gieterij*, Vol. 5, Apr. 1931, pages 47–49.

Modern practice for making acid-proof castings favors the use of high Si alloys. This requires either a crucible, oil-fired or electric furnace in preference to a cupola furnace. Addition of Ni even in percentages as low as 0.5% is beneficial. High temperatures and quick melting are required. This is readily attained with oil-fired, drum-shaped, rotatory furnaces. HSvK(22)

Molding of a Hollow Base with Template. (Schablonenmässige Herstellung der Form zu einem schalenförmigen Untersatz.) R. LOEWER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, June 12, 1931, pages 482–483.

Detailed description of the molding process. Ha(22)

Progress in Foundry Practice in the First Half Year of 1930. (Fortschritte in Giessereiwesen im ersten Halbjahr 1930.) H. JUNGBLUTH & P. A. HELLER. *Stahl und Eisen*, Vol. 51, June 11, 1931, pages 772–775.

The article reviews the literature on the subject noted above, covering (1) structure and properties of cast iron, (2) melting practice, (3) molding and cleaning, (4) standards, testing, etc. GN(22)

Testing the Hardness of Chilled Castings. II. (Die Prüfung der Härte von Schalenhartguss.) O. KEUNE. *Krupp'sche Monatshefte*, Vol. 12, Jan. 1931, pages 9–16.

The article gives the results of comprehensive tests on the application of the Brinell test in testing chilled cast iron. The errors involved are due to: (1) the ball impressions being off-round, (2) the occurrence of cracks along the edges of the impressions, (3) the kind of ball used. It is shown, however, that a satisfactory accordance between various readings can be obtained; the deviation generally does not amount to more than 1% from the mean value. The Brinell test may, therefore, be used successfully in testing chilled castings. GN(22)

Melting in the Metal Foundry. (Die Schmelzerei in der Metallgiesserei.) A. KRETZLER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 31, 1931, pages 624–627.

Different methods of firing for melting metals are discussed and examples are given of the calculation of the cost of operation of a coke crucible, tilting gas crucible, oil-fired tilting furnace and an electric furnace. These methods are compared. The economy of the melting plant depends on the investment in the melting furnaces, their efficiency, the price of fuel and the daily melting capacity. The two last mentioned factors determine the selection of the most economical furnace. Ha(22)

The Determination of the Piece-Time in Foundries for the Production of Manually Molded Castings. (Die Stückzeitbestimmung in der Giesserien bei Herstellung von handgeformten Gussstücken.) GÉZA JANDL. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 20, 1931, pages 157–162.

The methods for determining the price per piece to be paid to the workman for a single and quantity production are discussed. A new, more exact, way is described which is based on volume, surface and peculiarities of the piece under consideration. Several examples illustrate the method which is being applied at present and a few results are given. Ha(22)

Aluminum Castings. (Het Gieten van Aluminium.) GUST KREBS. *De Gieterij*, Vol. 4, July 1930, pages 112–115.

Sand-cast Al should be poured into molds made with sand which is not packed too tightly. Porosity due to the presence of gases or shrinkage may be avoided by casting at higher temperature and by providing means for an even solidification. The best castings are obtained in properly vented iron molds. HSvK(22)

Some Notes on the Structure of the British Foundry Industry. VINCENT C. FAULKNER. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, June 1931, pages 1–19.

Review of the situation as to foundries in the various branches of industry. CHL(22)

Capacity Increase of Molding Machines by Suitable but Simple Means Using Existing Pattern-Plates and Molding Boxes. (Leistungssteigerung von Formmachinen durch zweckmässige aber einfache Hilfsmittel, unter Benutzung der vorhandenen Modellplatten und Formkästen.) W. GOETZE-CLAREN. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 20, 1931, pages 162–165.

The manner in which molding boxes of different sizes and pattern-plates of unequal heights can be made generally useful for pin-lifting machines is shown. The increase of capacity obtained does not require more wages nor investment of capital. Ha(22)

Castings of Automobile Pistons. (Het Gieten van Zuigers voor Automobielmotoren.) L. HELDER. *De Gieterij*, Vol. 5, June 1931, pages 79–81.

A brief description of modern practice of casting automobile pistons with an alloy containing 85% Al and 15% Cu in preheated cast iron molds. The alloy is poured at a temperature of 720–760° C. HSvK(22)

Molding Practice for Heat-Treated Aluminum Alloy Castings. LEWIS H. FAWCETT. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Sept. 1931, pages 297–311.

Methods and precautions necessary in the production of castings of Al with 4–5% Cu are outlined. Prevention of cracks and checks is considered from molding, core-making and design standpoints. CHL(22)

The Speed of Rotation in the Centrifugal-Casting Process. J. E. HURST. *Foundry Trade Journal*, Vol. 45, Sept. 3, 1931, pages 145–147.

The author considers mathematically the conditions governing the movement of liquids under the influence of centrifugal force when rotated in containers; he obtains equations by means of which values for a constant can be calculated. This constant can be employed in determining the relationship between peripheral velocity and diameter of casting. The article is accompanied by 5 figures and particulars are given in tables of the rotational speeds which have been used in various processes for the centrifugal casting of pipes, etc. OWE(22)

Note on the Influence of Superheating Molten Cast Iron. J. E. HURST. *Foundry Trade Journal*, Vol. 43, Nov. 20, 1930, page 351.

Gives results of experiments on the effect of superheating molten cast Fe on its physical and mechanical properties. Experiments made on castings produced by centrifugal process. The tensile strength, stiffness and Brinell hardness are slightly higher in superheated material. Superheated material is liable to extensive unsoundness. Loss in Si content is about 0.4%. Superheating produces a grayer Fe. VSP(22)

The Effect of the Treatment of the Melt on Gas Content and Shrinkage of White and Gray Cast Iron. (Einfluss der Schmelzbehandlung auf den Gasgehalt und die Schwindung von weissem und grauem Gusseisen.) P. BARDENHEUER & W. BOTTENBERG. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 11, 1931, Report 181, pages 149–159; *Stahl und Eisen*, Vol. 51, July 16, 1931, page 917.

Four white and 4 gray cast irons were tested. The effect of superheating the liquid iron on gas content and shrinkage, in particular on the expansion with beginning solidification, was studied. The total amount of gases, H and CO, were determined by the hot extraction method. A special instrument was designed to take shrinkage curves. The cast irons were superheated at various temperatures and cast in sand molds. With the white cast irons, shrinkage and gas content increase with superheating time and temperature. Gray cast iron expands more during the solidification, due to the formation of graphite so that the gas content has a less pronounced effect. Gas content and expansion also increase with the superheating temperature. In pouring into preheated molds (540° C.) gas content and expansion are smaller, since with slow cooling a large amount of the gases escapes before solidification. A gray cast iron, remelted several times and always heated at the same temperature, shows a gradual decrease of the gas content and a corresponding decrease of the expansion. The expansion during solidification has a bearing on the total shrinkage which may vary by 10% according to the treatment of the melt. GN(22)

Properties of Molding Sands. (Einiges über Eigenschaften der Formsande.) A. AULICH & W. LEWERENZ. *Giesserei*, Vol. 17, Sept. 5, 1930, pages 875–878.

In making the compression test on molding sands, a special device is fitted to the machine which shows the "yield point" that is, the load at which the sand test piece commences to bulge. If this value is plotted as a percentage of the final crushing load, it is found that the figure gives an indication of the clay content and grain size of the sand. Ha(22)

Removing Sand from Deep-Cored Pockets. J. J. BAUM. *Iron & Steel of Canada*, Vol. 14, May 1931, page 1.

Chemical methods that may be adopted for removing sand from pockets in castings are described and reference is made to materials which can be employed as inhibitors of metal attack. OWE(22)

Storage and Preparation of Molding Materials. (Lagerung und Aufbereitung von Formstoffen.) FR. BROBECK. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 6, 1931, pages 197–200.

The preparing plant of a foundry of medium size is described, taking into account delivery and storage of the raw materials. The preparation of the single materials takes place separately according to wet or dry casting with the use of simple machines. A lay-out of the plant and its equipment is given. Ha(22)

Investigation of Core-Oils. (Onderzoek van Kernolies.) W. BAUKHAGE. *De Gieterij*, Vol. 5, Aug. 1931, pages 97–103.

Using washed river sand between 60 and 100 mesh in the ratio of 10 portions of coarse to 3 parts of fine sand, the author made a number of determinations of tensile strengths with oil-sand cores. Comparative tests were performed with linseed oil, linseed oil varnish, core-oil 2, Smithco 2 and Kordek Corebinder, the last named containing potato starch as a binder. The following factors affecting the strength were studied: (1) percentage of oil, (2) period of drying and (3) temperature of drying. With 1% of oil and a drying period of 2 hrs., the highest tensile strengths were obtained for a drying temperature of about 200° C. With increasing percentage of oil, other factors being equal, the tensile strength increased but not regularly. In some cases, a decrease in tensile strength was noted when there was more than 3% oil. Among other factors which influence the results, the following are discussed: (1) the age of the core; (2) the method of mixing oil and core sand; (3) the preparation of the moist sand; (4) the temperature of the sand; (5) the air circulation in the drying oven; (6) the temperature of the cores when tested. Core binders containing flour should be dried at once for obvious reasons. A sample of "Quella," for instance, gave cores which were the weaker the longer they were left alone before being dried. HSvK(22)

Electric Process Iron for Cylinder and Cylinder-Head Castings. H. E. BROMER. *Iron & Steel Industry & British Foundryman*, Vol. 4, Sept. 1931, pages 399–402.

Both the duplexing and cold-melting process are used, depending on demands for castings. Electric process has the advantage of controlling C and Si contents of cast Fe. Uniformity in Brinell hardness is claimed for the superheated electric Fe. A general comparison of transverse tests on plain and alloyed cast irons is given. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. CHL(22)

Systematic Distribution of Overhead Expenses in the Foundry. (Die planmässige Unkostenbewirtschaft in der Giesserei.) W. BREMER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 3, 1931, pages 277–281.

Discussion of costs for labor and material. A systematic check-up of expenses of a foundry is shown in diagrams and tables. Ha(22)

Modern Practice in Non-Ferrous Foundries. (Neuzeitliche Arbeitswesen in der Metallgiesserei.) E. BECKER. *Zeitschrift für die Gesamte Giessereipraxis*, Vol. 51, Oct. 26, 1930, pages 173–174; Nov. 2, 1930, pages 177–178.

Treatment of scrap and secondary metal is discussed. Foundry cleaning methods are also considered. Ha(22)

Casting of a Bed Plate of a Large Lathe. (Exécution d'un bati de grosse machine outil.) M. CONSTANT. *Revue de Fonderie Moderne*, Vol. 25, July 25, 1931, pages 261–266; Aug. 10, 1931, pages 281–287.

Detailed discussion of methods of molding, arrangement of cores, casting, buoyancy forces on the cores, etc., for very large pieces. The advantages of molding in a trench or half-trench are compared. Ha(22)

A Comparison of Natural Bonded and Synthetic Molding Sands for the Steel Foundry. H. J. COLE. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Aug. 1931, pages 161–173.

See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. CHL(22)

Chemical Composition as Employed for Classifying Carbon and Alloy Steels for Castings. R. A. BULL. *Transactions & Bulletin, American Foundrymen's Association*, Vol. 2, Sept. 1931, pages 257–274; *Iron Age*, Vol. 128, July 16, 1931, pages 174–175, 207.

The present confusing state which exists with regard to designation of various grades of steel castings is discussed. A suggested classification consisting of 2 principal groups for castings is proposed. One group subdivided the steel castings to be considered into 9 divisions as being of the regular carbon grade; the other group or 3 divisions includes those steel castings that are considered as being of the special carbon grade. CHL+VSP(22)

Molding and Casting of Centrifugal Pumps. (Het Vormen en Gieten van een Centrifugalpomp.) M. BROSTRÖM. *De Gieterij*, Vol. 5, June 1931, pages 74–77.

Experience has taught that vertical molding of centrifugal pumps of large dimensions produces the best castings. A detailed description of the molding of a centrifugal pump weighing 130 tons is given. HSvK(22)

Bronze Pressure Castings. J. E. CROWN. *Metal Industry*, N. Y., Vol. 29, Aug 1931, pages 335–337.

Among the alloys used for pressure castings is Cu 87.25: Ni 0.75: Sn 9: Zn 3, twice melted and poured around 1950° F. Machine finish allowance should not be excessive for pressure castings. PRK(22)

"Ratching" of Molding Sand. (Het Bratsen van Vormzand.) J. DERLAGE. *De Gieterij*, Vol. 4, June–July 1930, pages 89–93, 107–111.

Includes discussion. The various ingredients of molding sand are discussed and an attempt is made to explain the formation of scabs on castings. Scabs are supposed to form largely as a result of incomplete escape of gases. Casting imperfections due to faulty casting can be avoided by suitable design of gates, sprues and runners. Insufficient porosity may be caused by (1) sand of non-uniform grain size, (2) sand with too much clay, (3) uneven distribution of coal and (or) clay, (4) too much coal, (5) too lean sand, (6) too hard packing and (7) incomplete drying. HSvK(22)

Principles of Molding for Steel Castings. (Etude sur le moulage de l'acier.) P. CROISET. Dunod, Paris, 1931. Paper, 7 × 10 inches, 206 pages. Price 64 Fr.

This is a somewhat contemplative discussion of steel molding practice from a broad point of view. The methods of avoidance of shrink holes, gas holes, warping and other defects are discussed with emphasis on their fundamental causes. The discussion is not very specific, and the book might be classed as dealing only in generalities. But as the treatment is thought-provoking, the book is valuable.

Considerable space is given to a discussion of the solubility of gases in steel, which raises many questions without answering them. Incidental comments on metallurgical phases of steel foundry practice and on the properties of molding sands are given too briefly to be very informative. It is stated that to obtain cast steel without blowholes, the most common practice is to use 0.4–0.8% Mn, 0.2–0.4% Si, and 0.1–0.15% Al, which would indicate that the French founder uses rather large doses of Al. Malleable Iron. H. H. EBERT. *Iron & Steel Industry & British Foundryman*, Vol. 4, June 1931, pages 293–294.

General. CHL(22)

Casting Operation in Iron and Steel Foundries. H. H. EBERT. *Iron & Steel Industry & British Foundryman*, Vol. 4, Oct. 1930, pages 3–4.

Discusses those tasks which must be done and measures which must be taken in the foundry to bring the liquid iron or steel from the melting furnace to the casting mold, treating particularly the overcoming of hydrostatic pressure, transporting of the metal, casting appliances, inclined castings and pouring temperatures. CHL(22)

Brass and Bronze Founding. H. C. DEWS. *Metal Industry*, London, Vol. 36, Jan. 17, 1930, pages 93–96.

Deals with some of the more important uses and with the technique of founding. The necessity of further research is considered. The products of brass and bronze foundry are divided into 2 groups: ingots and castings. Casting conditions are somewhat different in brass foundries than in bronze foundries. The several uses of bronze call for somewhat different compositions of alloys. The major production of bronze is of alloys of medium Sn content. Most brass alloys are readily mechanically worked and find their chief use in engineering. VSP(22)

Making a Bend Pipe Core in Oil Sand. THOMAS DAVIS. *Iron & Steel Industry & British Foundryman*, Vol. 4, Aug. 1931, pages 367, 370.

Descriptive. CHL(22)

Technical Control in Manufacture of Cast Iron Pipe. T. C. EARNILL. *Canadian Foundryman*, Vol. 22, Apr. 1931, pages 9–11.

Reference is made to the sand most suitable for pipe-casting, to the ideal core material and its preparation, to the condition of the iron most satisfactory for the production of pipes and of iron mixtures which have served satisfactorily in this connection. The article is accompanied by a photograph, showing the casting of a pipe in a sand-spun mold. OWE(22)

Plywood in the Pattern Shop. F. C. EDWARDS. *Foundry Trade Journal*, Vol. 45, Aug. 20, 1931, pages 119, 122.

An article accompanied by 5 figs. which assist in making clear the uses to which plywood may be put in the pattern shop. OWE(22)

The Use of Fluorspar in the Cupola Furnace. (Het Gebruik van Vloeispaat in dem Koepeloven.) F. B. M. DEURVORST. *De Gieterij*, Vol. 4, Aug. 1930, pages 125–134.

Contains 14 references (mostly German). Partial replacement of "hardstone" (a variety of limestone, containing 52.7% CaO, 2.1% Al_2O_3, 1.2% Fe_2O_3) by fluorspar does not affect the melting process. A slight attack of the furnace lining is, however, noticeable. The slag is free from fluorine. The harmful effect on the vegetation is unmistakable. HSvK(22)

Molding a Large Cushion Block. (Het Vormen van een groot Kussenblok.) L. DESMEDT. *De Gieterij*, Vol. 4, Aug. 1930, pages 130–132.

Full directions for molding a cushion block of 7500 kg. The importance of proper venting to avoid formation of scabs is particularly emphasized. HSvK(22)

Producing Hydraulic Cylinder Castings. E. LONGDEN. *Iron & Steel Industry & British Foundryman*, Vol. 4, Jan. 1931, pages 115–118.

The author has chosen the production of a single heavy casting 20 tons in weight (a hydraulic cylinder) which will serve to illustrate the craft of molding and the practical application of foundry metallurgy. Three methods for patternwork, molding and coremaking are discussed and compared. CHL(22)

FURNACES & FUELS (23)

Possibilities of the Electric Furnace. (Les possibilites du four electrique.) PAUL MARTHOUREY. *Revue de Métallurgie*. Vol. 28, Feb. 1931, pages 101–116; Nov. 1931, pages 139–150.

A review of the development of the electric furnace since its conception is given under the heading of different countries. Weak and strong points of it in connection with the industrial peculiarities of the countries are discussed. The present tendencies favor a 3-phase Heroult furnace on account of its simplicity, long life of lining and bottom. The power installed per ton doubled within the last 10 years. The voltage needed depends on the types of the operations to be conducted and the materials used. Higher voltages are to be preferred from economic considerations. Electrical equipment should be calculated to withstand an overloading 5–10 times higher than the normal load. The choice of the electrodes depends on many factors. A set of specifications both for furnace and transformer installations is given. Electric furnace offers particular advantages for deoxidation and production of clean steel by permitting control of time and temperature as well as slag. It is applicable to the manufacture of a number of alloys and steels a list of which is given. Starting with cold scrap and having the bath well deoxidized before Si addition, it is possible to produce uniformly transformer sheets with 3.5–4.0% Si having the losses between 1 and 1.3 watt for 10,000 gausses and 50 cycles in sheets 0.35 mm. thick. Electric cast irons give a much tougher product than the cupola, often 1.5–3 times as resistant to impact as the former. Electric irons are particularly suited for black heart malleable. For white heart a simple treatment as for the former cannot be applied and a proper adjustment of composition, quenching, the speed of annealing and the oxidizing medium must be considered. In the manufacture of rails the defects of all other steel making methods are emphasized. Segregations demand too high a rolling temperature. Insufficient deoxidation when the metal is still boiling in the ingot mold interferes with the proper pouring temperature and too fast a rolling accentuates the troubles. Rapid carburization leads to a coarse grain without having any strength at high temperatures. Carburization with anthracite should be avoided. Much better results are obtained when the steel is brought to the proper carbon content gradually. Electric furnace offers a very valuable tool for manufacture of rails, which have very good physical properties, thus justifying the extra cost. Steel castings made in an electric furnace have better physical properties than those made by any other process. As an example of the products which can be made in it is given a Ni-Cr steel with better properties for railroad work than 13% Mn steel. It was described previously (Paul Marthourey. "Les aciers speciaux resistant à l'usure pour appareils de voie." *Revue mensuelle de l'Industrie des Voies ferres et Transports automobiles*, Dec. 1929, Jan. 1930) and only results of physical testing are given here. A set of rules for economic operation of electric furnaces is offered. JDG(23)

Electric Gas Purification in a Gas Producer Plant. (Elektrische Gasreinigung im Gaserzeugerbetrieb.) H. KNICKENBERG. *Stahl und Eisen*, Vol. 51, Mar. 26, 1931, page 390.

The article briefly describes the two-step Cottrell electric gas purification unit installed at the Böhler steel plant at Düsseldorf-Oberkassel for the separation of tar and oil from producer gas generated with Rhenish bituminous coal. Data on the cost of operation, are given. GN(23)

More about Furnace Atmospheres and How to Make Them Behave. W. W. KEMP. *R-S Industrial Review*, No. 31, July 1931, page 6.

A few general remarks on producing and maintaining required atmospheres with gas burners and different arrangements for mixing gas and air. Ha(23)

The Transformation of Mixed Gas in the Open Hearth Furnace. (Die Umwandlung des Mischgases im Siemens-Martin-Ofen.) W. HEILIGENSTAEDT. *Stahl und Eisen*, Vol. 51, Aug. 20, 1931, pages 1045–1056.

Report 214 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. It is shown that the reactions of mixed gas in the open hearth furnace can be quantitatively studied by means of the equilibrium conditions of the water gas reaction and the CO_2–CO reaction, provided the constants of equilibrium of the water gas and the CO_2-CO reaction are known. These constants were determined in the special case of this investigation. The constants were used to study the effect of the water vapor content of the mixed gas upon the carbon separation and the heat consumption of the reactions. Up to a saturation temperature of 20° C., the effect of the vapor is of relatively minor importance but the carbon separation decreases with an increase of the vapor content of the gas, so that no free C appears at temperatures around 50° C. Simultaneously with increasing vapor content, the heat consumption of the reaction increases and, therefore, the preheating temperature can be decreased. The temperature relations and the heat transfer in the gas checkers and its effects upon the gas reactions in the furnace were also studied. GN(23)

The Rotating Furnace, Stein-Brackelsberg, for Melting Cast Iron Heated by Powdered Coal. (Le four rotatif Stein-Brackelsberg chauffé au charbon pulvérisé pour fusion de la fonte.) JOUANNO. *Revue Technique Luxembourgeoise*, Vol. 23, May–June 1931, pages 93–105.

This furnace can be moved in 2 directions in the vertical plane. It is used for making malleable iron and cast iron of high resistance. The advantages claimed for this type are: Heating with powdered coal allows complete combustion without excess of air and the possibility of obtaining high temperatures without oxidation of the metal. The slag on top of the melt protects the metal from action by air and combustion gases. The loss due to burning is very small, in contrast to the cupola process. The analysis of the melt differs very little from the analysis of the charge. Because of the rotating motion, the bath is heated not only at the surface, but the heat which is stored in the walls is recuperated. This accelerates melting and lengthens the life of the furnace lining. Temperatures of 1500° to 1550° C. can be obtained without fear of oxidation. The safety of the heating system against explosions assures regularity of production. The average time required for a melt in a 5 ton furnace is about 3 hrs. The paper is supplemented and illustrated with complete details of analyses of product and charge, performance of furnace, heat balance and micrographic examinations. Ha(23)

Two-Chamber Regenerative Gas Furnaces with Constant Flow. (Fours à deux chambres au gaz régénérateur et à courantgazeux continu.) HENRY FEY. *Revue Technique Luxembourgeoise*, Vol. 23, Jan.-Feb. 1931, pages 20–28.

A general description of the development of the furnace with a divided horseshoe flame is given and it is shown that the low thermal efficiency has prevented its wider application. A new improved construction is characterized by the division of the air current coming from one of the regenerative chambers. One part enters the furnace by pressure and by tube burners and passes on in a continuous flow. The other part is used for the combustion of the cold gas directed directly against the openings of the regenerative chamber; the flame serves for the direct heating of the regenerative air chamber. Three new models of this furnace are described. Test results are reproduced which showed an efficiency of the chambers of more than 85%. Ha(23)

Present Tendencies in Heat-Treating Furnaces. (Tendances actuelles des fours pour traitements thermiques.) M. FOURMANT. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 291–298.

General discussion of requirements and the methods by which they are met. Lists various types of continuous furnaces. HWG(23)

A Study of the Combustible Nature of Solid Fuels. R. V. Frost. *Heating, Piping & Air Conditioning*, Vol. 3, Sept. 1931, pages 771–777.

A number of charts are presented showing the relationship between draft and rate of combustion for samples of several different fuels. The fuel requiring the smallest amount of draft to maintain combustion is charcoal, producing 1.3% ash. The next on the list is coke, with 10.0% ash. Next come 2 types of anthracite producing 10.8 and 27.9% ash, respectively. A sample of Rhode Island graphitic anthracite, producing 22.4% ash, is next on the chart. This type of fuel offers so high a resistance to combustion that it is not offered for sale as a fuel. Yet this supposedly valueless anthracite apparently will burn much more readily than Pennsylvania anthracite, with 7.6% ash, the curve for which is last on the chart, requiring the greatest amount of draft to produce combustion. It is apparent that the usual tests of coal fail when applied to the determination of the combustible character of the coal. Neither appearance, density, chemical composition nor location can be used as an indicator. The only positive means of determining the combustible character of a coal before it is put to use is to make a specific test for that particular purpose. WAT(23)

Heating of Mixers with Blast Furnace Gas. (Le chauffage des mélangeurs par gaz de haut fourneaux.) Chas. D'Huart. *Revue Technique Luxembourgeoise*, Vol. 23, Mar.-Apr. 1931, pages 76–83.

Up to the present time, this method of heating has been used very little. A few installations which are operated experimentally and can, in an emergency, be switched over to other gas supplies are described. See also *Metals & Alloys*, Vol. 2, Apr. 1931, page 87. Ha(23)

Use of Blast Furnace Gas. (Quelques considérations sur l'utilization rationnelle du gaz de haut fourneau.) M. Gangler. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th Session Liege, June 1930, pages 55–71.

Describes practice at the Differdange plant. HWG(23)

Roasting and Heating in America. (Roste und Feuerungen in Amerika.) Hans Heitler. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 12, May 1931, pages 155–156.

Abridgment of article presented before the Prime Movers Committee of the National Electric Light Association, June 1929. MAB(23)

The Principles of Design of Cupola Furnaces, the Determination of Their Size and Their Mathematical Relations. (Die Rechnungsgrundlagen des Giessereischachtofens, ihre Grössenbestimmung und mathematische Gesetzmässigkeit.) A. Achenbach. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 13, 1931, pages 217–225; Mar. 20, 1931, pages 241–245.

The conditions and the principal factors of the performance of a cupola furnace are theoretically discussed and practical formulas developed which are later proved to hold good in actual tests. It can be stated that the principal factors, i. e., charge, amount of air, coke and volume of the cupola form fixed mathematical relations from which no deviations are admissable. The calculations are given in detail and 23 references are cited. Ha(23)

Operation of Buess Hocker-Type Rotary Furnace. (Die Arbeitsweise des Buess-Schankeldrehofens.) W. Buess. *Giesserei*, Vol. 17, Nov. 14, 1930, pages 1121–1122.

The advantages of an eccentrically arranged rocker furnace over the usual drum furnace are discussed and an example is given which shows better mixing in the bath. Ha(23)

Practical Applications of Heat in Metallurgy. Harry Dobrin. *Iron Age*, Vol. 128, July 16, 1931, pages 180–181, 208.

Abstract of a paper read before Association of Iron & Steel Electrical Engineers in Cleveland, June 17, 1931. In contrast to the high efficiencies in the boiler plant, general efficiencies in metallurgical heating hardly average 20% for most reheating processes. In sheet and tin mill industries, the general efficiencies are about 18%. The author discusses the method he uses in fuel economy and gives the results obtained. VSP(23)

Automatic Combustion Control Systems for Wire Furnaces. F. Aschner & H. Mayer-Witten. *Wire & Wire Products*, Vol. 6, July 1931, pages 292–294; Sept. 1931, pages 363–365.

Describes regulating systems developed in Germany, types of regulators, methods of operations and results of service. The importance of automatic furnace control, particularly in the manufacture of wire, is pointed out. Economy of the process and quality of the product depends largely on the furnaces. The second installment describes temperature control and pressure control apparatus used in German installations. Ha(23)

Experiences with Stationary and Tiltable Open-Hearth Furnaces with Mixed Gas Heating. (Erfahrungen und feststehenden und kippbaren Siemens-Martin-Oefen mit Mischgasbeheizung.) H. Bansen. *Stahl und Eisen*, Vol. 51, Aug. 6, 1931, pages 989–995.

Report 211 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The article describes the furnace operation with mixed gas heating, considers tests to suck larger quantities of waste gas through the gas checkers, studies the effect of the humidity of the gas and the gas composition by analysis and the effect of the furnace type upon the gas composition. GN(23)

Industrial Furnaces for Gas. IV. Heat Treating Pot Furnaces. V. Heat Treating Oven Furnaces. VI. Heat Treating. Muffled, Combination and Rotary Furnaces. VII. Special Furnaces for Heat Treating. VIII. Forging. Rivet Heaters. Lawrence E. Biemiller. *American Gas Journal*, Vol. 134, May 1931, pages 57–59; June 1931, pages 39–41; July 1931, pages 48–49; Aug. 1931, pages 47–48; Sept. 1931, pages 54–56.

IV. Defines the various terms used in heat treating Considers specifically the cyanide furnace, the lead hardening furnace, oil tempering furnaces and temperature control on pot furnaces. V. This article considers single deck low temperature oven furnaces, single deck high speed steel furnaces and double deck furnaces. VI. The difference between "standard" and "special" furnaces is defined: the former is made in definite sizes and is available from manufacturers' stock; the other is made to individual specification. The small combination furnace, permitting several kinds of heat treating on a small scale, the muffled oven furnaces, combination furnaces for general tool work and rotary carburizers are described. VII. The article considers 2 typical furnaces for hardening, one which can be used for either hardening or annealing, one annealing furnace with 2 conveyors operating in opposite directions, as well as one continuous normalizing furnace which gives a very specialized anneal. Each type is described and its particular advantages and applications evaluated. VIII. The different forging temperatures for different steels are given and discussed. The application of the forging operation in rivet heating is described and advantages explained. MAB(23)

Characteristic Properties of Foundry Coke. (Kennzeichnende Eigenschaften von Giessereikoks.) F. Brinckmann & A. Nehmitz. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, June 26, 1931, pages 515–516.

Besides limited moisture, ash and content of S, coke for cupola furnaces must also have a certain strength. A method by which an objective impression may be gained is described. It consists of a "drop-drum" test. A drum 1 m. in diameter and 1 m. long which rotates for 4 mins. with 25 r. p. m. is filled with 50 kg. of coke. After this, the coke is sorted by means of sieves; parts of more than 40 mm. are designated as strong; from 20 to 40 mm., as brittle; and the parts under 10 mm. as abrasive. The results of such a test are said to show great regularity. Ha(23)

Electric Reflection Furnace. (Elektrischer Reflexionsofen.) C. Benedicks & J. Haerdén. *Teknisk Tidskrift*, Vol. 61, 1931, pages 149–155.

The construction and operation of an electric reflecting arc furnace with an elliptical Cu mirror are described. It is particularly suitable for vacuum work. The principal advantage consists of the melting of substances of high melting temperature without bringing them in contact with foreign materials, especially crucible walls; moreover, in the short time of bringing the temperature up, 2000° C. can easily be reached. An efficiency of 25% of the total energy supplied to the electric arc has been obtained. Ha(23)

Oil or Gas as an Industrial Fuel. G. F. Beach. *R-S Industrial Heat Review*, No. 31, July 1931, pages 3–4.

A few general points of comparison for deciding upon the use of oil or gas. Ha(23)

A Study of Heat Regenerators. (Étude sur les appareils régénérateurs de chaleur a inversions.) Defrance & Sanger. *Revue de Métallurgie*, Vol. 28, June 1931, pages 305–323; July 1931, pages 367–374; Aug. 1931, pages 426–447.

The calculation and design of heat regenerators do not present any particular difficulties from the theoretical standpoint but the results obtained by different investigators are pronouncedly different. The present work is a comprehensive mathematical analysis of the methods used. JDG(23)

Fuel Impregnation by the Slag in the Hearth and Bosh of the Blast Furnace. C. D. Abell. *Foundry Trade Journal*, Vol. 43, Dec. 11, 1930, page 410.

The fuel in a cold blast furnace becomes impregnated with slag. The several types of impregnation products are: the amber slag which occurs as an interstitial mineral in association with coke in the hearth; the mineralized fuel, occurring with amber slag in central zone of hearth is essentially a silicified C, retaining fuel ash in chemical combination; and white slag, obtained by burning away of mineralized fuel and is low in Fe and Mn content. VSP(23)

Cost of Dry Methods of Gas Purification. (Étude du prix de revient des 1000 M³/hr de gaz épuré dans les épurations modernes pax voie sèche.) M. Derclaye. *Congrés International des Mines de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 9–24.

Includes discussion. Comparison of cost of bag filtration vs. electrostatic precipitation of dust from gas to be used for gas engines, etc. with the advantage usually in favor of the bag system. The discussors disagreed and preferred wet methods to either of the dry methods. HWG(23)

Determination of Time Required for Heating of Steel. T. J. Ess. *Iron & Steel Engineer*, Vol. 8, July 1931, pages 317–321.

Information from various sources is assembled and correlated. Variables are so numerous as to make each case an individual problem. Ten items are enumerated which must be considered. Certain rules for the determination of time required for heating steel are given. $Y = C(e)^{mx}$ relates time, Y in minutes, to x, temperature in ° F. desired in the stock where C and m are constants for the given furnace temperature and have values as follows:

Furnace Temp.	C	m.
2100° F.	1.75	.002025
2450	2.9	.00135
2680	3.25	.000965

Allowable temperature difference from center to outside limits the rapidity of heating. This factor is of greatest importance in heat treatments and of least importance in reheating operations. For a given shape the time for the surface to approach the furnace temperature is proportional to the thickness. Temperature difference in the stock is proportional to the thickness. With stock 4" thick diffusion is the controlling factor and on thin stock the surface absorption of heat controls the heating time. A factor called diffusivity is inversely proportional to the heating time and is composed of conductivity/(specific heat × density). Effects of furnace size and flame conditions are discussed. Qualifications to the rules for determining time of heating are tabulated. An equation to act as the basis for the construction of a chart for forge furnace heating is given by $t = a\,V^m/O^n$ where t is the time, V stock volume, O stock surface, a and m constants determined by test. Times for heating various sizes of stock 1" to 7" to temperatures of 1000–1800° F. with a furnace temperature 200° F. higher are tabulated. These data show the effect of recalescence which is important in heat treatments. The times determined by the five rules given are compared in a tabulation. Discrepancies and applications of the rules are discussed. Charts are shown which eliminate the necessity for mathematical skill in the application of two of the rules, one of which is most applicable to heat treatment operations. WLC(23)

REFRACTORIES & FURNACE MATERIALS (24)

Refractory Materials for the Induction Furnace. J. H. Chesters & W. J. Rees. *Iron & Steel Industry & British Foundryman*, Vol. 4, July 1931, pages 347–348; *Foundry Trade Journal*, Vol. 45, Aug. 13, 1931, pages 105–107; Aug. 20, 1931, pages 113–114.

Paper read at the annual meeting of the British Iron & Steel Institute in London, in which the authors discuss linings for horizontal ring-type and corcless-type induction furnaces. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 190. OWE+CHL(24)

A New Source of Raw Materials for High-Temperature Heat Insulation. J. Bryte Barnett & R. H. Heilman. *Proceedings Engineers' Society of Western Pennsylvania*, Vol. 47, July 1931, pages 349–371.

The bulk of refractory materials consists of but three chemical compounds, silica, alumina and combinations of these in the form of clays. Of these silica and clays have been extensively used in the production of heat insulating materials, but alumina has had but little application until recently. The following table gives the thermal conductivities of the powdered materials investigated:

Material	Conductivity B. t. u./ft.² hr./° F./inch 1000° F.	1600° F.	Loss on Ignition Percent
Monohydrated bauxite	0.713	0.935	16.3
Alumina (Bayer process)	2.010	2.820	1.0
Alumina (fusion process)	3.710	5.180	0
Alumina fume	0.750	1.175	1.8
Aluminum monohydrated	1.160	1.540	17.4
Aluminum trihydrated	2.400	3.240	34.7
Bauxite residue	0.650	0.870	16.3
Bauxite residue floated	0.420	0.650	12.9
Bauxite	2.680	3.410	30.3
Diatomite	0.864	1.134	5.0

The following table presents the thermal conductivities of the molded insulation investigated.

Molded Insulation	Recommended Temp. ° F.	Conductivity B. t. u./ft.² h./° F./inch 1000° F.	1600° F.
"Superex" block	1600	0.966	1.270
Natural "Sil-o cel" brick	1600	0.925	1.170
"Sil-o-cel" C22 brick	2000	1.750	2.220
"Sil-o-cel" C25 brick	2500	2.100	2.540
"Nonpareil" brick	1600	1.160	1.420
"Armstrong" brick	2500	1.920	2.620
Monohydrated bauxite brick	1900	0.710	0.910
Aluminum monohydrated brick	2500	1.950	2.500

GASES IN METALS (25)

Dissolved Nitrogen Embrittles Weld Metal. F. R. HENSEL & E. I. LARSEN. *Metal Progress*, Vol. 20, Sept. 1931, page 44–47.

Technique for the prevention of gas absorption during welding is described. Age hardening effects in metal deposited in welds without precautions for preventing the absorption of nitrogen are discussed. Microphotographs show the distribution and condition of the nitride after various treatments. If the Ni is held below 0.05%, age hardening effects are greatly reduced or eliminated. WLC(25)

Influence of the Atmosphere on the Scaling of Mild Steel. W. H. BLACKBURN & J. W. COBB. *Journal Society Chemical Industry*, Vol. 49, Nov. 28, 1930, pages 455T–462T; Dec. 5, 1930, pages 463T–466T.

Small specimens of mild steel were heated for 3 hrs. at 1000° in various atmospheres and the increase of weight was determined. The loss of metallic iron, when no excess of O was present, was found to be 0.43% with oil as fuel and 0.24% with coke. With 3% O in the atmosphere, the losses were 1.27% and 1.09%. The exclusion of O is of the greatest importance, if the scaling is to be minimized. The addition of 0.5% O results in rapid scale formation. The mixing of the fuel gas with O and the elimination of free O should be completed before the metal is reached. In the absence of free O scaling was definitely lessened by fuels which were rich in C and low in H. The use of high-temperature coke with a low moisture content is recommended. The influence of the addition of various reducing gases to the furnace atmosphere upon complete prevention of scaling and upon 50% reduction of scale formation was determined. The amount of reducing agent necessary to secure complete absence of scaling or even a reduction to 50% was much larger than could be used in ordinary practice, representing a quantity of potential heat of the same order as that of the primary fuel. H was the most effective agent for the complete prevention of scaling, involving the least thermal expenditure, while CO involved the greatest. Even with H as anti-scaling agent, however, the thermal expenditure amounted to 1.3 or 0.8 times the thermal value of the fuel, depending on whether oil or coke was used. The thermally stable methane was much less effective than either ethylene or acetylene, which are both readily decomposed by heat. The free C (soot), however, present in a smoky atmosphere, was found to have a negligible effect in preventing scale. A clear atmosphere, with the same reducing gases, CO and H, was found to be equally effective. In adding CO and H to the furnace atmosphere, the former was found to be more efficient up to the point where scale formation was reduced 43%. Beyond this, H was more efficient. There seems to be no ground for assuming that a smoky reducing flame from bituminous coal would be any more effective in minimizing scaling than a clear reducing flame from coke. The "neutral" atmosphere from coke would be definitely less scaling than that from coal on account of the lower content of water vapor. Ha(25)

INSPECTION (26)

Inspection on an 18-Story Welded Building. A. R. ELLIS. *Welding*, Vol. 2, July 1931, pages 440–443.

Over 13,000 lineal feet of welding were examined by the stethoscopic method. The construction was speeded up by a patented erection seat welded to one member whereby the number of guy lines could be reduced. Ha(26)

Welding Inspection. R. KRAUS. *Canadian Foundryman*, Vol. 22, Aug. 1931, pages 12–15.

Paper presented at a symposium on welding under the auspices of the A. W. S. and the A. S. T. M. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 152. OWE(26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Nickel in Cast Iron. W. T. GRIFFITHS. *Foundry Trade Journal*, Vol. 43, Nov. 27, 1930, pages 369, 370.

Includes discussion. Abstract of paper read before the Wales, Monmouth and West of England Branch of the Institute of British Foundrymen at Cardiff. Reviews various researches which have been carried out. Ni acted the same as Si in regard to graphitizing. Si should be lowered when adding Ni if best results are to be obtained. Ni is used to avoid porosity in castings. Use of Ni in cast Fe and also with Cr produces a wear-resisting material. VSP(27)

The Dependence of the Magnetic Induction of Structural Steels upon the Chemical Composition. (Die Abhängigkeit der magnetischen Induktion bei Baustahlen von der chemischen Zusammensetzung.) E. GEROLD. *Stahl und Eisen*, Vol. 51, May 14, 1931, pages 613–615.

Report from the Research Institute of the United Steel Works at Dortmund. Steels containing 0.03–0.10% C and not more than 2% of Al, Si, Cu, Ni, Mo, Mn and Cr were tested. The induction was determined for various field strengths and compared with that obtained by calculation. The measured and calculated data are in satisfactory agreement for higher field strengths above 7.7 ampere turns/cm. Therefore, the induction can be calculated from the chemical composition. GN(27)

Influence of Small Additions on the Softening of Copper. (Einfluss von kleinen Zusätzen auf die Enthärtung des Kupfers.) ARTHUR BURKHARDT. *Metallwirtschaft*, Vol. 10, Aug. 21, 1931, pages 657–659.

Contains 7 references. Alloys containing 0.1% and 0.5% of Ag, Si, Fe, Zn, Cd, Al, Ni, Cr, Mg, Sn, Mn and P with electrolytic Cu were cast, hot pressed at 900°. They were then reduced 50% by cold rolling, cut in several pieces, annealed for 2 hrs. at from 250° to 550° C. and tested for Brinell hardness. The results are given in tabular and graphic form. All additions raise the softening temperature somewhat, especially 0.5% additions of Ag, Fe, Cr, Mg, Mn and Sn. Mg and Sn have a distinct hardening effect on Cu. Fe and Cr alloys which were quenched from 900° before cold working have a higher softening temperature than those which were cooled slowly, due to formation of alloys affected by heat treatment. Some Modern Alloy Steel Developments. BASIL BARHAM. *Iron & Steel Industry & British Foundryman*. Vol. 4, Sept. 1931, page 411.

General. CHL(27)

Some Properties of Austenitic Gray Cast Iron. (Sur quelques propriétés des fontes grises austenitiques.) MARCEL BALLAY. *Comptes Rendus*, Vol. 193, July 6, 1931, pages 47–49.

The author describes the results of certain experiments on the effect of Cu, Al and Cr on the properties of gray cast irons having an austenitic structure. In particular, a mixture containing 2.71% total C, 1.45% Si, 1.30% Mn, 14.82% Ni, 1.40% Cr and 0.30% Cu was investigated. To this material Cu was added in such proportions as to give a series of alloys containing from 0.30 to 12.25% Cu. The author remarks that the solubility in the solid state of Cu in ordinary cast Fe is in the neighborhood of 5%, whereas the solubility of Cu in the austenitic material was in the neighborhood of 10%. The effect of introducing Cu was to increase the resistance of the material to attack in hydrochloric acid, and a table is given showing the relationship between the Cu content and the loss in weight of the series of alloys investigated in mg./dm.^{2}/day. The author also deals with the effect of Cr and Al on the corrosion of austenitic cast Fe in nitric acid and on the resistance of the material to oxidation at 800° C. Attention is also directed to the effects of Cu and Si on the hardness and the electrical resistivity of these materials OWE(27)

Influence of Phosphorus, Sulphur, Nickel and Chromium on the Growth of Cast Iron. (Der Einfluss von Phosphor, Schwefel, Nickel und Chrom auf das Wachstum des Gusseisens.) O. BAUER & K. SIPP. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 15–23; *Giesseri*, Vol. 17, Oct. 10, 1930, pages 989–995.

Other constituents being held quite constant in each series, the influence of the elements named was studied on a total of 30 compositions. Specimens were heated for 8 periods of 10 hours each at 650° C., and then for 8 more 10 hour periods at 850° C. The irons high in P (0.9–1.3%) gave poorest results in both series. At 650°, the 4 best irons studied were

C	*Si*	*Mn*	*P*	*S*	*Ni*	*Cr*
3.4	1	0.5	0.2	0.3	—	—
3.3	1	0.5	0.5	0.35	—	—
3.0	0.75	0.8	0.2	0.1	1.35	—
3.0	1.75	0.8	0.2	0.1	1.35	0.8, with 1.05–1.15%

growth, while the worst was

C	*Si*	*Mn*	*P*	*S*	*Ni*	
3.3	1.4	0.7	0.2	0.1	0.2	— With 2% at

850° C. the 4 best were

C	*Si*	*Mn*	*P*	*S*	*Ni*	*Cr*	*Growth %*
3.3	0.7	0.7	0.2	0.1	0.3	—	1.9
3.0	0.8	0.8	0.2	0.1	0.5	—	2.7
3.0	0.8	0.8	0.2	0.1	1.0	—	2.2
3.0	0.8	0.8	0.2	0.1	1.4	—	2.8, and

	C	*Si*	*Mn*	*P*	*S*			
the worst	3.0	1.5	0.5	1.2	0.2	—	—	with 6.3%.

The measurements are recorded at various stages of the test for the 30 irons. It is concluded that growth in the primary period, due to carbide decomposition, is hindered by Mn and Cr, aided by Si, P and Ni, with S and C neutral except that very high S retards growth. The second stage of growth is due to exterior conditions, i. e., oxidation. HWG+Ha(27)

The Influence of the Silicon Content and the Cooling Velocity on the Constitution of the Phosphide Eutectic in Cast Iron. (Der Einfluss des Siliziumgehaltes und der Abkühlungsgeschwindigkeit auf die Konstitution des Phosphideutektikums im Gusseisen.) P. BARDENHEUER & M. KÜNKELE. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 22, 1931, pages 417–422.

See *Metals & Alloys*, Vol. 2, Jan. 1931, page 18. Ha(27)

Nickel Addition Affects Bearing Wear Resistance. JAMES BRINN. *Foundry*, Vol. 59, Aug. 15, 1931, pages 40–41.

Alloys used in tests were the regular 80% Cu, 10% Sn and 10% Pb, and alloys which have been derived from these alloys by replacing 0.5, 1, 2 and 3% Sn with the same percentage of Ni. Addition of 2% Ni to an 80% Cu, 10% Sn and 10% Pb alloy prevents segregation of Pb but decreases resistance to wear. Ni addition also causes a tendency in the metal to oxidize both in the crucible and mold. Fine grain structure and greater hardness can be obtained by pouring metal into chill instead of sand molds. The author concludes that improvement in grain structure and Brinell hardness of bearing bronzes lessens wear resistance. VSP(27)

Influence of Small Quantities of Foreign Metals upon the Properties of Refined Zinc. (Einfluss geringer Mengen von Fremdmetallen auf die Eigenschaften von Raffinadezink.) O. BAUER & P. ZUNKER. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XVII, 1931, pages 24–34.

See *Metals & Alloys*, Vol. 2, Sept. 1931, page 190. (27)

The Influence of Silicon on Nickel Steel. R. HARRISON. *Iron & Steel Institute, Advance Copy* No. 10, Sept. 1931, 19 pages.

The properties of 4% Ni steels containing 0.4% C, 0.3–0.8% Mn and 0.05–0.87% Si were investigated. Si raises the transformation points found on both heating and cooling. As forged, rolled, normalized or hardened, the Si increased the hardness, but the increase was not marked. In the hardened condition, Si had very little effect on the properties. Si tends to reduce the mass effect, but Mn has a more pronounced influence. Si increases the tendency to temper brittleness. In general, it was found that in the type of steels studied up to 0.87% Si did not have much effect on the mechanical properties. Contains 6 references. JLG(27)

Investigation of the Effects of Impurities on Copper. Part VII. The Effect of Antimony on Copper. Part VIII. The Combined Effect of Antimony and Arsenic on Copper. S. L. ARCHBUTT & W. E. PRYTHERCH. *Journal Institute of Metals*, Vol. 45, No. 1, 1931, page 144 (with discussion); abstracted in *Engineer*, Vol. 151, Apr. 3, 1931, page 374; *Iron Age*, Vol. 127, June 4, 1931, page 1815; discussion in *Engineering*, Vol. 131, Mar. 27, 1931, page 410.

Influence of Molybdenum and Nickel on Cast Iron. J. CHALLONSONNET. *Iron Age*, Vol. 127, June 4, 1931, page 1901.

Abstract translation of article in *Revue de Métallurgie*, Dec. 1930. Discusses the properties of synthetic and commercial cast Fe as influenced by 0.25 to 0.5% Mo, with and without the addition of 1 to 2% Ni. See also *Metals & Alloys*, Vol. 2, Aug. 1931, page 153. VSP(27)

The Effect of Molybdenum on Medium-Carbon Steel Containing 1 to 2.5 Per Cent of Manganese. G. BURNS (Research Department, Woolwich). *Iron & Steel Institute, Advance Copy* No. 5, Sept. 1931, 16 pages.

The effects of several tenths of a percent Mo on the properties of heat treated steels containing 0.3% C with 1.2% Mn and the same quantity of C with 2.2% Mn were investigated. Cooling curves showed that 0.3% Mo lowered the Ar_1 point in the steel containing 1.2% Mn. The addition of 0.3% Mo did not greatly affect the properties of the normalized steels, but it had a beneficial effect on the quenched and tempered steels. The addition of 0.15–0.25% Mo practically eliminated the tendency to temper-brittleness, and reduced the mass effect. The properties of the Mn-Mo steel treated to give a Brinell hardness of 250 are found to approximate those of a Ni-Cr-Mo steel treated to give the same hardness. Tests on several steels treated to a Brinell hardness of 250 include tensile, torsion, impact and Sankey bend tests. The paper contains several tables giving tensile and impact values for the various steels after various heat treatments. Contains 6 references. JLG(27)

INSTRUMENTS & CONTROLLERS (28)

Heat Supervision of an Electric Gas Purification Plant. (Wärmetechnische Ueberwachung einer elektrischen Gichtgas-Reinigungsanlage.) S. HINRICHS. *Stahl und Eisen*, Vol. 51, June 25, 1931, pages 788–790.

Investigating Vibration Trouble in the Field. PETER DAVEY. *Iron Age* Vol. 127, Feb. 5, 1931, pages 452–455.

Describes the use of the vibrometer which utilizes the stroboscopic principle for checking both rotary and vibratory motions. It includes a "breaker head" by means of which light flashes may be regulated so that they occur once every revolution. It may be applied to high and low speed machinery. VSP(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Corrosion of Steels at High Temperatures. II, III. (Corrosione degli-acciai a temperatura elevata. II, III.) LUIGI LOSANA. *Industria Chimica*, Vol. 5, Mar. 1930, pages 288–291; May 1930, pages 565–571.

The corrosion of 8 samples of steels containing varying proportions of Ni, Cr, Mn, W, V, Mo, Si, P, S and C was measured between 600° and 1050° C., the presence of air, as well as of exhaust gases from gasoline motors. Results indicate that steels containing W, and Mo resist this corrosion much better than chrome steel (stainless). These steels show higher resistance to exhaust gases in comparison with ordinary steel than they do to air. The effect of Cr and Ni, as well as C, on the resistance of motor valves to corrosion at temperatures up to 1000° has been studied. In steel with 10% Cr, 4–10% Ni improves the resistance slightly, while 10–15% Ni gives a decided improvement. With 10–12% Ni steel, 10–11% Cr gives the best results. C has little effect, except to improve low Ni steels slightly. WHB(29)

On Ni-Cu-Alloys at Low Temperatures. (Ueber Ni-Cu-legierungen in tiefen Temperaturen.) KRUPKOWSKI & DEHAAS. *Zeitschrift für Metallkunde*, Vol. 23, July 1931, page 196.

Furnace Scale on Forging Heats. W. E. JOMINY & D. W. MURPHY. *Metal Progress*, Vol. 20, Sept. 1931, pages 48–53.

Paper presents data on scaling of C and alloy steels at forging heats in atmospheres resulting from the combustion of various proportions of air-gas mixture. The gas used was a coke oven-carburetted water gas of the following composition; CO_2, 4.0%; unsaturated hydrocarbons, 8.0%; O_2, 2.0%; CO, 20%; H_2, 45.0%; CH_4, 13.0%; and N_2, 9.0%. The effect of H_2 and CO in preventing scaling and of CO_2 and H_2O in the promotion of scaling are discussed. To reduce materially the scaling experienced when a neutral air-gas mixture is burned (CO, 0.0–0.5%), very large excess of gas is necessary resulting in 14.0% of CO in the products of combustion and to eliminate scale an excess resulting in 16.5% is necessary. Any excess of air on the other side of the neutral mixture results in considerable increase in scale. WLC(29)

The Surface Decarburization of Steel at Heat-Treating Temperatures. W. E. JOMINY. *Engineering Research Bulletin*, No. 18, *Department of Engineering Research*, University of Michigan, Ann Arbor, Mich., March 1931, 51 pages.

The surface decarburization of steel at heat-treating temperatures is influenced by a large number of factors, of which the more important are furnace atmospheres, pressures, temperatures, periods of exposure and scale on the steel. To make any predictions regarding the decarburizing action, the effect of the individual gases that may be present in the furnace atmospheres must be considered in relation to one another. It is often possible to use sufficiently short periods of exposure to minimize the decarburizing effects. These effects obtain in most steels, although steels of certain compositions may decarburize more rapidly than others. (29)

Heat-Resistant and Corrosion-Resistant Steels for Steam Boiler Construction. (Warmfeste und korrosionbeständige Stähle für den Dampfkesselbau.) H. JUNGBLUTH & H. MUELLER. *Krupp'sche Monatshefte*, Vol. 12, July 1931, pages 179–188.

Description of exhaustive tests which were made in the Krupp laboratories to develop heat-resistant and corrosion-resistant steels, especially for the construction of high pressure steam boilers. It was found that Cr-Mo or Cr-Si-Mo steels with about 1% Cr showed the desired qualities to a high degree up to temperatures of 600°–650° C.; another group of Cr-Si-Mo steels with about 6% Cr and 1.5% Si had a somewhat lower permanent strength but they were more resistant to corrosion up to 800° C. The authors, however, believe that, from the test results, the steels of the first class are preferable. The properties of the steels are discussed at great length. Ha(29)

Resistance of Ordinary Steel at High Temperatures. (Sur la résistance à chaud des aciers ordinaires.) LEON GUILLET, JEAN GALIBOURG & MICHEL SAMSOEN. *Comptes Rendus*, Vol. 192, Apr. 15, 1931, pages 861–863.

The authors describe an investigation involving the use of a modified Martin's extensometer designed by them (*Comptes Rendus*, Vol. 188, pages 1205–1208). In the present investigation, a series of boiler steels have been tested, and values for 2 mechanical characteristics of the steels at temperatures of 225°, 325°, 425° and 525°, respectively, are tabulated. The 2 characteristics referred to are known as (1) the limit of instantaneous extension proportional to load (when passing from one load to a higher, observations are made of the instantaneous extensions which, for loads between zero and a certain limiting value, are proportional to the excessive load which has just been applied, but are not proportional to the excessive load if and when loads exceeding this limit have been reached) and (2) the limit of instantaneous extension without a creep in relation to time (after the instantaneous extention has been measured, provided the load exceeds a certain limiting value and is continuously applied to the sample under test, the sample extends continuously with time, but ultimately extension reaches a limit at which it stops). The authors claim that the following generalization has been proved: Properly speaking, a true elastic limit does not exist, even for steels at ordinary temperatures, the apparent permanence of dimensions after a slight load has been applied being an illusion resulting from the imperfect sensitivity of our measuring instruments. WAT(29)

On the Magnetization of Single Crystals of Cobalt at High Temperatures. KOTARO HONDA & HAKAR MASUMOTO. *Science Reports of the Tohoku Imperial University*, Vol. 20, July 1931, pages 323–341.

Measurements of the magnetization of single crystals of Co at temperatures ranging from −190° to +390° C. were made by the ballistic method. The magnetization at ordinary temperatures in the direction of the 0001 axis rises at first rapidly and attains an asymptotic value in a comparatively weak field. As the temperature is raised, the intensity of magnetization in weak fields increases up to 230°, and then decreases. Magnetization in the directions of the 1010 and the 1120 axes at ordinary temperatures is very difficult, so that even in a field of 10,000 gausses the saturation value is not reached. As the temperature is raised, the magnetization in these directions becomes easier up to 300°, but above this temperature, it does not change appreciably. The saturation value of the magnetization of a cobalt crystal at absolute zero has been estimated to be 1446 C. G. S. units. WAT(29)

Higher Pressures and Temperatures as They Affect the Design, Installation and Maintenance of Piping. J. J. HARMAN. *Heating, Piping & Air Conditioning*. Vol. 1, Dec. 1930, page 785–991; Vol. 2, Jan. 1931, pages 20–29; Feb. 1931, pages 106–112.

A series of three articles on the general effect of temperature on the properties of metals used in pressure piping. A safe stress-temperature curve is given for a 0.30% C cast steel, to temperatures of 1000° F. Creep is discussed from a view point of design, installation and maintenance. Many illustrations and diagrams of pipe design are given which illustrate the subject. WAT(29)

Relation Between Temperature and Tensile Strength. E. KIEFT. *Iron Age*, Vol. 126, July 31, 1930, page 282.

Abstract of paper read before the Association of Iron & Steel Electrical Engineers at Buffalo. Knowledge of strength of steel at various temperatures is important in rolling mill analysis. Relation between temperatures and tensile strength of iron and steel.

Some short-time high-temperature tension tests. (Quelques résultats d'essais de traction à chaud.) P. HERMAN & R. MOSSOUX. *Congrès International des Mines, de la Métallurgie et la de Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June, 1930, pages 321–326.

Shows sketch of mirror extensometer. Steels for gasoline motor valves were tested at 750° C. The apparent elastic limit at 750° places the Cr, Cr Ni, Cr Co and Cr Ni W valve steels tested in about the same order as their lives in actual service. The sensitivity of the extensometer is not discussed. A steel of about 0.30% C, 11% Cr, 25½% Ni, 11½% W, 2½% Mn, ½ Si showed an apparent elastic limit at 750° C. of 44,000 lbs./in.², tensile strength of 54,000, these being considerably higher than for the other steels tested. Increase in Co content does not improve the high temperature properties of these steels as much as does an increase in Ni. HWG(29)

Flow of Steels at Elevated Temperatures. F. P. COFFIN & T. H. SWISHER. *Preprint, American Society Mechanical Engineers*, June 1931, 7 pages.

Flow tests of steels at elevated temperatures, as carried on in the Research Laboratory of the General Electric Company, are described. Various methods of testing are used. Some are for the purpose of obtaining a mass of information in the shortest possible time, here the rate of flow is measured for a series of successively increased temperatures. Others are designed to furnish more fundamental information regarding the nature of flow, here new specimens are subjected to constant stress at a constant temperature. A third is the constant-extension test where the stress is varied with time to maintain a constant total elongation (elastic plus plastic). The apparatus is described and pictured in some detail. Values for the stress producing 1% flow in 100,000 hours are given at 450° C. for 37 low alloy content Ni, Cr, Mo, V, W steels. Additional values are given in some cases for temperatures 400, 500 and 550° C. Time-elongation and stress-flow rate curves illustrated the results. WAT(29)

Steam Turbine Materials for High Temperatures. R. C. ALLEN. *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 meeting, *American Society for Testing Materials*, pages 550–556, 7 figures.

Past turbines mostly run below 750° F., present standard is around 850° F. and temperatures to 1000° F. are being considered. The high temperature end of a turbine must be designed to allow for creep, 0.01% per year being set as the limit, in planning for a life of 15 to 25 years. A 50" diameter cylinder, creeping at that rate, will increase 0.075" in 15 years, increasing clearance 75% and decreasing efficiency 7%. Tangential stress in the inner bore is 11,000 lbs./in.² Working stress in turbine blades may reach 20,000 lbs./in.² Cylinders are usually 0.30–0.35% carbon steel castings when operation is at 800° F. For 900° F. with tangential bore stress of nearly 7000 lbs./in.² a 0.30 C, 2.10 Ni, 0.80 Cr, 0.30 MO steel is used. Huge studs are required for such a cylinder, each one carrying 680,000 lb. load. Threads are copper or chromium plated to prevent galling. To prevent galling under the heads, case hardened or nitrided washers are used. The studs are 0.10 C, 12% Cr (Ni 0.60% maximum), quenched from 1700° F., drawn at 1200° F. It may be necessary to warm the studs at the same time that cylinder and spindle are warmed up in starting. The turbine spindle for 800° F., 3600 r. p. m. is 0.40 C steel, peripheral stress about 9700 lbs./in.² For higher temperatures a 0.38 C, 0.50 Cr, 2.50 Ni, 0.30 Mo steel is used. Turbine blades are commonly made of a stainless steel, same composition as given above for studs. This is the best available material. It can be stressed (0.01% creep per year) to 18,000 lbs./in.² at 875° F. or 5500 lbs./in.² at 1000° F. Better bolt steels and alloy steels for castings to serve at elevated temperatures are urgently needed. HWG(29)

The Wrought Austenitic Alloys (at High Temperatures). R. H. ABORN & E. C. BAIN. *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931 meeting, *American Society for Testing Materials*, pages 322–346; 4 figures, 10 tables, 53 references.

Clear statement of factors affecting corrosion resistance at room temperature and mechanical properties at high temperatures of wrought austenitic alloys varying from 0.05 to 0.20% C, 0.30 to 2¹/₂₅% Si, 7 to 30% Ni and 16 to 30% Cr. High temperature uses depend on the fundamental fact that austenite, γ-iron, has greater resistance to change of shape than has ferrite, α-iron, probably because of higher recrystallization temperature and lower recrystallization velocity. Addition of elements such as Cr, W and Mo to austenite aids in this. The austenitic structure may be imparted either by Ni or by Mn. All the high temperature data presented relate to that produced by Ni. Detailed data are tabulated. These alloys have but ⅓ the thermal conductivity of iron which may lead to local overheating. They have a high thermal expa ion, which may lead to buckling. Intelligent application is necessary. Cr tends to stabilize α Fe, Ni and C to stabilize γ-iron. Some combinations not in true equilibrium tend to be sluggish and remain in the γ-state. Cold work tends toward establishment of true equilibrium. Separation of (*a*) high temperature ferrite, (*b*) low temperature ferrite (*c*) carbide may occur in some compositions at some temperatures. These matters are shown by diagrams and discussed in relation to embrittlement of 18–8, add to variations in its composition. Intercrystalline weakness resulting from long sojourn at 1165–1380° F. is lessened by addition of W. Carbide precipitation is accompanied by depletion of Cr in the surrounding territory, since Cr goes out of solution to enter the carbide. Until this inhomogeneity is repaired by diffusion through heating to a sufficiently high temperature the depleted areas do not contain the proper amount of Cr. The depleted areas are susceptible to corrosion, including that by furnace gases. Carbide precipitation near welds has to be remedied by heat-treatment. Straight 18–8 has shown fine service in many applications under severe conditions to 1110° F. and modern low carbon material is usually applicable to 1250° F. In some cases carbide precipitation has been reported after very long exposure to 850° F. Much detailed data on short time tests, creep tests, mechanical properties at room temperature after prolonged heating, etc., are given in tables too extensive for abstracing. The article is of interest in many ways aside from its high temperature data. HWG(29)

Flow of Steel at High Temperatures. F. H. NORTON. *Preprint, American Society of Mechanical Engineers*, Oct. 1930, 5 pages.

Presented at the National Petroleum meeting of the American Society of Mechanical Engineers in Tulsa, Okla., October 6–8, 1930. In general there are three types of flow. The first is turbulent flow where the velocity is proportional to the square root of the stress. This type of flow is encountered in gases, and liquids of low viscosity. The second type is viscous flow where the velocity is proportional to the stress. The third type is plastic flow where no simple relation has previously been found to exist between stress and flow rate. It is this last type of flow that is of interest in dealing with steel at high temperatures. In general all solids are composed of rigid particles held together by a more viscous medium. In a single crystal, these particles are molecules held together by attractive forces; in a mass of wet clay, the particles are crystals of clay substance, often of colloidal size, held together by a film of water; and in steel, the particles may be molecules in a crystal, or the crystals themselves held in a comparatively viscous intergrain material. When a material of this kind is deformed, the friction between the particles must be overcome. The thicker and more fluid the interparticle film, the less will be the friction. The apparatus used was the same as was described in Norton's book (Creep of Steels at High Temperatures, McGraw-Hill Book Co., New York City, $3.00). Two steels were investigated, 0.05% C, 18–8 Cr-Ni, and 0.59% C, 28–23 Cr-Ni. The temperature and duration of tests were as follows: 650° F., 4100 hrs.; 1000° F., 4200 hrs. and 1350° F., 2300 hrs. It would appear from the limited data that all steels at temperatures above 650° F. have the same characteristics which may be expressed by: Rate of Flow = K (Stress)^5
That is, if the stress is doubled the rate of flow increases 32 times. There is no indication of a limit below which there will be no creep. Work is now in progress on a number of other plastic and viscous materials in order to correlate their flow characteristics. The preliminary results indicate that the fifth power relation holds for materials as widely different as steel and soft clay. The possibility is suggested of a new regime of flow at low rates, logically connected to viscous flow and turbulent flow at the higher rates. WAT(29)

Influence of Grain Size on the Properties and Corrosion Resistance of the 18–8 Iron-Chromium-Nickel Alloy for Elevated Temperature Service. H. D. NEWELL. *Preprint, American Society for Steel Treating*, Sept. 1931, 61 pages.

Preliminary experiments showing the influence of heat treatment on grain size, were made on 0.08% carbon, cold drawn 18–8 alloy and on 0.056% carbon, hot rolled 18–8 alloy. Data are presented on the short time ultimate strength and ductility of 0.05 and 0.14% carbon 18–8 alloy in conditions representing several grain sizes. These data cover both 1 and 150 hours heating in the range 800° to 1700° F. A discussion of the test results is given with reference to the effect of grain size on creep as found by other investigators. The grain size of the alloys is shown by photomicrographs for conditions representing hot-rolled and quenched from 1900, 2100 and 2300° F. The effect of reheating at 1200° F. on corrosion resistance, is shown by tests in dilute sulphuric acid and by susceptibility to attack in the Strauss solution. The distribution of carbides, precipitation by heating at 1200° F. is shown in photomicrographs of 0.05 and 0.14% carbon alloy in the hot-rolled condition and after quenching from 1900, 2100 and 2300° F. The following conclusions have been drawn from the results of this investigation: The ductility of both 0.05 and 0.14% carbon, 18–8 alloy, on rupture at elevated temperatures is greatly affected by the grain size of the metal. Fine-grained alloys show much more ductility than do coarse-grained ones at temperatures in the approximate range 1100° to 1700° F. The short time ultimate strength is also affected by grain size, but this is not considered of importance as other investigators have shown creep to be somewhat superior in coarse-grained 18–8 alloy at temperatures of 1180° F. The corrosion resistance of 0.05% carbon alloy is much less impaired by reheating within the fine carbide precipitation range than is the 0.14% carbon alloy. Susceptibility to intergranular attack after reheating is influenced by both carbon content and grain size. Fine-grained low carbon alloy is not susceptible to intergranular corrosion on reheating, but may become so if the grain size is sufficiently large. This is due to the amount or extent of grain boundaries available to the precipitated carbides. The higher carbon alloy (0.14% C) is susceptible even in a fine-grained condition by reason of the greater amount of carbon available for precipitation. Low carbon alloy having a fine-grain size is to be preferred for elevated temperature service involving corrosion because of its greater ductility and non-susceptibility to intergranular attack. Restriction of the carbon content and of the grain size of the 18–8 alloy produces the most satisfactory condition for ductility at elevated temperatures and for maintenance of corrosion resistance properties at or after heating to a temperature sufficient for carbide precipitation. WAT(29)

The Behavior of Steel at High Temperatures. V. B. HARLEY MASON. *Engineer*, Vol. 152, July 31, 1931, pages 115.

No new data. A discussion of the creep test from the early developments to the present. Dickinson's early work is discussed and compared with Hatfield's "time-yield." The work of Lea, Batson and Tapsell and Norton is also reviewed. The disadvantage of the long time required to make satisfactory creep tests is emphasized. Hatfield's "time-yield" test for this reason, according to the author, has many advantages. The article is entirely a résumé of the developments, advantages and disadvantages of the creep test. WAT(29)

Program for Work of the French Committee for Study of the Resistance of Metals at High Temperatures. (Mise en route des travaux du Comité pour l'etude de la resistance des Métaux à chaud.) J. GALIBOURG. *Revue de Métallurgie*, Vol. 28, May 1931, page 259.

At the suggestion of the French Association for Testing Materials, this committee has been formed, representing 12 steel producers, 10 fabricators and 12 users. The work of the committee will be the exclusive property of those supporting the work. The program includes the formation of subcommittees on definitions and terminology; on technique of testing methods, to compare tests on wires and bars by tension, torsional creep, the method of oscillations, etc.; on apparatus for temperature control, and measurement of creep; on summarizing the literature; on procurement of materials to be tested; on survey of metals used and properties needed; on forgeability of metals. HWG(29)

Strength of Materials Subjected to Shear at High Temperatures. *Preprint, American Society Mechanical Engineers*, June 1931, 13 pages.

The paper relates to an experimental program which is basically fundamental in the study of creep. Uniformly pure shear is produced in a thin tubular specimen submitted to twist, whereas the usual method employs a solid bar in tension. The material tested was an 0.34% carbon seamless steel tubing. The paper includes physical properties in torsion and tension at room temperature, results on the effect of different rates of loading on "short-time" tests on the modulus of elasticity and ultimate strength in shear at temperatures up to 500° C, "long-time" tests in shear at 400° and 500° C. An accelerated method for making creep tests is described. Building vibrations and jars increase the rate of creep, although not in all cases. A mathematical formula is derived whereby the effect of temperature fluctuations may be calculated for the rate of creep in shear. The apparatus and specimen used are described in detail. The results are illustrated with numerous curves. WAT(29)

Impact Characteristics of Steel Rails at Low Temperatures. J. F. CUNNINGHAM & J. GILCHRIST. *Preprint American Society for Steel Treating*, Sept. 1931, 13 pages.

In the specimens of rails tested, and in 0.92% C, 0.42% C steels and open-hearth iron, there is a gradual decrease in impact resistance down to temperatures of −28° to −29° C. (−18° to −20° F.). From this point the resistance to impact has reversals at fairly definite temperatures. Uncertain results may be expected to shock resistance below a temperature of −29° C. (−20° F.). The only material tested and showing these reversals is the 0.10% C rivet steel which does not suffer from reduced temperatures until −40° F. is reached. Ferrite grains from small to medium sizes will resist the lower temperature effects better than larger grains. Medium grains of medium pearlite with a slight excess of ferrite are more resistant to impact at low temperatures than either coarse or fine pearlite. Any excessive amount of free ferrite at grain boundaries is especially susceptible to impact at low temperatures. The following conclusions are submitted for consideration. The orientation of the pearlite lamellae in relation to the direction of the impact stress will be found to have a considerable effect upon resultant values. Different components (cementite, ferrite, etc.) having different coefficients of contraction due to lowering of temperature, may cause minute strains in the structure which reach a maximum near a temperature of −28° to −29° C. (−18° to −20° F.). These coefficients may be constant down to −18° to −20° F. but not below that temperature. There is a vital need for more information concerning the behavior of metals at low temperatures. For the sake of economy the factors of safety in design must be lowered, and with airplane, automobile and railroad transportation demanding the utmost resistance in the severe winter in many parts of the continent, there is an important field of investigation in the low temperature, as well as the high temperature field. WAT(29)

Values and Boiler Fittings for 1900 Lb. and 900°. BRUNO BELOHLAVEK & ARTHUR J. HERSCHMANN. *Power*, Vol. 73, June 30, 1931, pages 1028–1031.

The authors are, engineer in charge and U. S. representative, respectively, of the Vitkovice Steel Works, Czechoslovakia. The article describes the values and boiler fittings for the steam pressure indicated, from a viewpoint of design rather than the material used. The analysis of steel was not given other than "Vitko" S. O. having a tensile strength of 78,000–92,000 lbs./in.^{2} and being rustless. Diagrams of the various valves and fittings are given. WAT(29)

Variations of the Resilience of Steel as a Function of the Temperature. J. DESSENT. *Revue Universal des Mines*, Series 8, Vol. 5, Feb. 1931, pages 97–99.

In hypoeutectoid carbon steels, the resilience increases with the temperature and reaches a maximum at or near ordinary temperatures, depending upon the carbon content. It then decreases to a minimum in the vicinity of 500° and then increases again very rapidly. The variation of the resilience with temperature is greater when the carbon content is lower. Pearlite and ferrite behave differently on heating and the resilience of a steel is the resultant of their change and depends on the proportion of these constituents present. In hypoeutectoid steels the resilience varies only slightly as a function of the temperature. WAT(29)

Zinc Alloys for High and Low Temperature Service. H. A. ANDERSON. *Preprint* for A. S. T. M.-A. S. M. E. Joint Research Committee Symposium on Effect of Temperature on Properties of Metals, June 1931, meeting *American Society for Testing Materials*, pages 179–197, 14 figures, 32 references.

Since zinc melts at 787° F., its alloys are not ordinarily considered in discussions of high temperature properties. Zinc and many of its alloys are weaker and more brittle below room temperature. The strength also falls at higher temperatures.—Ductility usually first falls, then rises to a maximum about 150° C., hence zinc is rolled at about that temperature. Zinc base die castings made from impure zinc or of improper compositions grow warp and become brittle in moist air at elevated temperatures. The present die casting alloy, made from 99.99% pure zinc and containing 4% Al, 3% Cu and 0.1% Mg is, however, very stable. Hitherto unpublished data on this alloy are plotted, the tensile strength falling in almost a straight line from about 50,000 lbs./in.^{2} at 32° F. to a bit under 6000 at 500° F. Elongation rises from 1½% to 35%. HWG(29)

Time Deformation—the Nature of "Creep Tests." G. R. BROPHY. *Metal Progress*, Vol. 20, Aug. 1931, pages 54–57.

Advance information on a paper to be presented before the American Society for Steel Treating Convention in Boston, September 1931. The purpose of the present paper is to present a study of the fundamentals of deformation and to suggest a possible short time method for consideration. The apparatus used and methods followed are essentially those described by Prof. Albert Sauveur in the Campbell Memorial Lecture before the American Society for Steel Treating in 1930. The type of test is essentially a torsional-creep test and temperatures between room and 485° C. were investigated. It was found, among the steels investigated, that three types could be recognized as having load-deformation curves of different characteristics. Type (1) has a stepped diagram up to some temperature, and above that temperature, a smooth curve. As the temperature of testing increases, the number of steps decreases, but each step increases in magnitude and, of course, the so-called plastic portion of the curve is displaced downward. This type of action is characteristic of annealed simple low carbon steel. Type (2) is characteristic of quenched, and quenched and drawn simple steels and of some alloy steels. Smooth deformation curves are obtained at room temperature and at higher temperatures, but at intermediate temperatures steps are found as before. It was found that those steels which show a stepped load-deformation diagram (types 1 and 2) lose the steps at some elevated temperature and that this temperature varies from 375° C. to 475° C. for the steels tested. The (3) type shows smooth load-deformation curves from room temperature up. As stated by Sauveur, this curve is characteristic of austenitic steels. WLC + WAT(29)

Cast Alloys for High Temperature Service. D. HANSON. *Foundry Trade Journal*, Vol. 44, June 4, 1931, pages 387–390.

The article is entirely a general discussion and review of the subject. Mechanical strength and chemical resistivity are the two chief factors to be considered in selecting materials for high temperature service. The type of service to which the material is to be subjected must be considered in the selection of the material to meet that service. The work of Pfeil on oxidation is discussed. Thermal expansion must be considered for in many cases it is the oxide layer that increases the chemical resistivity and this protective coating must be kept intact. Most heat resisting alloys are of the solid solution type. The futility of accelerated tests is discussed. In determining the strength characteristics actual service must be duplicated as nearly as possible. Castings in many cases are more serviceable for elevated temperature service than wrought materials. The author discusses the "available alloys" among which commercial cast irons, alloyed cast irons, alloys of copper and alloys of nickel-chromium-iron are included. WAT+OWE(29)

Heat Resisting Steels. H. N. Bassett. *Industrial Chemist*, Vol. 7, Aug. 1931, pages 318–319.

Cast iron can be used where temperatures do not exceed about 600° C. A 13% Cr steel may be used up to 800° C. with satisfaction. The latter, however, is not suitable for the valves of internal-combustion engines and for such purposes an alloy is used which contains 8 to 9% Cr and some 3 to 3½% Si. In Diesel engines and high-powered internal-combustion engines, Ni, Cr, W steels are employed because they have higher mechanical properties. Thus ERA/ATV steel (a Ni-Cr-W alloy) has a tensile strength of about 16 tons/in.² at 900° C. The remainder of this article discusses the work done by Bullens, Hadfield and Matthews to which references are made. RAW(29)

The Determination of Corrosion Resistance of Metallic Materials at Elevated Temperatures. (Ueber die Bestimmung der Korrosionsbeständigkeit metallischer Werkstoffe bei hohen Temperaturen.) J. Fritz & F. Borneffeld. *Krupp'sche Monatshefte*, Vol. 12, Aug.-Sept. 1931, pages 237–241.

The method used by Krupp determines the loss of metal under heating of from 120 to 240 hrs. at 500–1300° C. The furnace and procedure used is described and directions for the proper evaluation of the test results are given. Ha(29)

The Effect of Low Temperature on the Shock-Resisting Properties of New Wrought-Iron Chain. H. J. Gough & A. J. Murphy. *Proceedings Institution of Mechanical Engineers*, British, No. 5, Dec. 1930, pages 1159–1223.

The general results of the investigation may be summarized as follows: Best quality chain does not develop any brittleness in the absence of notches within the temperature range investigated, 17° to −78° C. The notched bar valve of best quality chain iron decreases but slightly as the temperature falls from 200° C. to air temperature. Notch brittleness commences at air temperatures and becomes increasingly evident as the temperature is further reduced, the rate of decrease of energy with falling temperature is greatest at a temperature intermediate between air temperature and 0° C. The shock-absorbing value of new ¾ inch wrought-iron chain, of high-quality material and manufacture, falls only slightly as the temperature of test is lowered from air temperature to −30° C. It falls at a very rapid rate as the temperature is further decreased to −78° C. This temperature brittleness is in most cases attributable to the welded scarf of the link, the end of which acts as an effective notch and causes failure on account of the notch brittleness to which chain iron has been shown to be subject. In several cases, however, evidence has been obtained which shows that a defective link (imperfect weld, accidental surface injury, etc.) may behave in a brittle manner at much higher temperatures (−10° C. in present tests). The brittleness associated with wrought iron at moderately low temperatures is not a persisting effect and disappears when normal temperatures are again attained. WAT(29)

Some Developments in High-Temperature Alloys in the Nickel–Cobalt–Iron System. C. R. Austin & G. P. Halliwell. *American Institute of Mining & Metallurgical Engineers, Technical Publication* No. 430, Sept. 1931, 21 pages.

Small melts of Ni-Co-Fe (Konel) alloys were made in an induction furnace, forged to bars and the short-time tensile properties at 600° C. obtained. Most of the alloys contained Ti, usually 2.5%. Samples were tested after annealing and after aging at 650° C. High proportional limit values shown by some of the alloys indicate the probability of high creep limits. Proportional limits at 600° C. between 50,000 and 70,000 lb./in.² were observed. An alloy containing 46.1% Ni, 24.86% Co, 7.02% Fe, 2.19% Ti and 18.74% Cr had the following properties at 600° C.: 57,000 lb./in.² proportional limit, 21% elongation and 21% reduction of area. This is markedly superior to the properties of a 70–30 Ni-Cr alloy. Many of the alloys were age hardenable. Although Ti appeared to be a necessary constituent of age-hardenable alloys, the compound responsible for the phenomenon was not determined. Data obtained by a special bend test for temperatures up to 800° C. are given. Contains 8 references. JLG(29)

An Instable State Found in an Fe-Ni-Alloy Which Cannot Be Eliminated at Even 1000° C. (Beispiel eines instabilen Zustandes in Legierungen, der sich auch bei 1000° C. nicht zur Reaktion bringen lässt. Fe-Ni-Legierungen.) L. Anastasiadis & W. Guertler. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, pages 189–190.

The paper presented before the Deutsche Gesellschaft für Metallkunde, Berlin, 1930 pertains to a phenomenon met with in pure Fe-Ni alloys: the impossibility of eliminating the super-cooling and super-heating of the $(\alpha + \beta)$ γ-transformation which was checked by electric resistance measurements. The instable state cannot be eliminated at even 1000° C. EF(29)

Temperature Coefficient of the Modulus of Rigidity of Aircraft Instrument Diaphragm and Spring Materials. W. G. Brombacher & E. R. Melton. *Review of Scientific Instruments*, Vol. 1, Nov. 1930, page 697.

Abstract of the Report No. 358, National Advisory Committee for Aeronautics, 1930. Al, duralumin, Monel Metal, brass, coin silver, Ni-Cu-Zn alloy, 3 carbon steels and 3 alloy steels (composition not stated in abstract). Effects of heat treatment on the temperature coefficient was determined for some of the materials. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 51. Ha(29)

Influence of Heat Treatment on the Electric Conductivity of Carbon Steels. (Einfluss der Wärmebehandlung auf die Leitfähigkeit von Kohlenstoffstählen.) M. Boussat. *Recherches et Inventions*, Vol. 12, Feb. 1931, pages 33–49; *Chemisches Zentralblatt*, Vol. 102, Apr. 29, 1931, pages 2663–2664.

The measuring methods to determine the electrical conductivity are described and possible errors discussed. Tests on steels with 0.10, 0.42 and 0.61% C show that electric conductivity and the temperature coefficient decrease with increasing content of C. It is further stated that between 0 and 200° C., the conductivity changes linearly with the temperature. Quenching increases the resistance of C steels while subsequent tempering reduces the resistance again to the resistance before hardening. Ha(29)

The Behavior of Various Light Metals at Low Temperatures. (Über das Verhalten verschiedener Leichtmetalle in der Kälte.) Franz Bollenrath & Joan Nemes. *Metallwirtschaft*, Vol. 10, July 31, 1931, pages 609–613; Aug. 7, 1931, pages 625–630.

Contains 7 references. The modulus of elasticity, modulus of deformation, elastic limit at 0.01 and 0.03% permanent elongation, yield point, tensile strength, elongation and reduction of area in static tension tests, and the specific impact energy, elongation and reduction of area in dynamic tensile tests were determined for 7 Al forging alloys and 2 Mg forging alloys in the range of +80 to −190° C. A special apparatus was used with ice, ice-salt mixtures, solid CO_2 and acetone and liquid air as cooling media. The static tensile properties of all alloys examined rise considerably with lowering temperature, while the elongation and reduction do not change as much. The Mg alloys become very brittle at low temperatures. Silumin and Lautal behave differently from the other Al alloys. The increase in tensile strength at low temperatures is accompanied by a drop in yield point and elastic limit. In the dynamic tests the specific impact energy is highest at moderately low temperatures for most of the alloys, while the elongation is practically constant except with the Mg alloys. Lowering of the temperature does not have as much effect on the dynamic properties as on the static properties and the Mg alloys are not as brittle in the dynamic tests. The results of the tests are given in tabular and graphic form. The conclusion reached is that all the alloys tested can be used at temperatures down to −190° C. CEM(29)

Possible Resistance Anomalies at Low Temperatures. (Sur des anomalies de la résistance aux basses températures.) S. Choubine. *Comptes Rendus*, Vol. 192, Apr. 27, 1931, pages 1020.

An anomalous low-temperature conductivity is to be expected in the case of metals having a number of conductivity-electron pairs, providing the smallest energy of the second zone of the electronic moment space is larger than the highest energy of the first zone. On the basis of Fermi's repartition function, there must be zero resistance in the above metals, even at temperatures above zero absolute, until T reaches a certain value at which the resistance becomes normal. The connection between this abnormal resistance and supraconductivity is discussed. WAT(29)

Recent Metallurgical Research in Relation to Marine Engineering. S. L. Archbutt. *Transactions Institute Marine Engineers*, Vol. 42, 1930, pages 295–346.

The limiting creep stress should be considered for design purposes at elevated temperatures. The nature of the atmosphere seems to influence the rate of creep and the mode of deformation. Intercrystalline fracture was found in some creep tests. A graph showing the relation between temperature, tensile strength, limiting creep stress and limit of proportionality for 0.17% C steel is given. Higher pressures and degrees of super-heat require a material superior to C steel. Creep characteristics are given for various alloys. Ni-Cr alloys and their derivatives are most suitable for temperature ranges of 600–1000° C. Limiting creep stress at the highest temperature increases with increasing Cr content. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 1. WHB(29)

The Oxidation of Some Copper Alloys. John Stanley Dunn (British Non-Ferrous Metals Research Association). *Institute of Metals, Advance Copy* No. 567, Sept. 1931, 24 pages.

The oxidation of Cu-Zn alloys containing as much as 40% Zn was studied. In a pure metal, the rate of oxidation at elevated temperatures is defined by the equation $W^2 = Kt$, where W is the weight of O_2 absorbed, K a constant and t the time. This equation would be expected to hold for some solid solutions. Experimental data proved that it holds for alloys containing from 0 to 12 and from 20 to 40% Zn. The high Zn alloys are oxidized at about 1/8 the rate of the high Cu alloys. The alloys containing less than 80% Cu all oxidize at about the same rate, and give rise to a coating that is almost pure ZnO. Those with more than 86% Cu oxidize at the same rate, and the oxide formed contains the metals in the same ratio as the original alloy. The oxidation of alloys between these 2 fields cannot be expressed by a simple equation. Cl compounds accelerate the rate of oxidation. Small quantities of As and Ni are without influence on the rate of oxidation, but even 0.1% Al has a protective effect. An alloy containing 1.9% Al was almost immune to oxidation at temperatures up to 800° C. Three Cu-Si alloys were studied. As much as 4.58% Si had little effect on the oxidation. Contains 10 references. JLG(29)

LEACHING (30)

Note on the Extraction of Copper from Oxidized Ores by Cyanide Solution. E. T. Dunstan. *Journal of the Chemical, Metallurgical & Mining Society of South Africa*, Vol. 31, May, 1931, page 294.

Discussion of the article abstracted in *Metals & Alloys*, Vol. 2, Aug. 1931, page 155. AHE(30)

The Recovery of Gold and Silver from the Ore of the Gem Lake Mine, East Central Manitoba. A. K. Anderson. *Canada Department of Mines, Mines Branch Report* No. 720, 1931, pages 58–64.

This quartz ore contained 3.5 oz. Au and 0.35 oz. Ag/t. with no As, Sb, Bi or Cu. Best recoveries were obtained by cyanidation and amalgamation, 98.5% of the Au and 97.3% of the Ag. Results are given of amalgamation, cyanidation and concentration alone and in combination. AHE(30)

The Recovery of Gold from the Ore of the Belledat-Goudreau Mine, Goudreau, Ontario. A. K. Anderson. *Canada Department of Mines, Mines Branch Report* 720, 1931, pages 71–81.

The ore consisted of quartz gangue carrying small amounts of iron sulphides and graphite and little PbS. It assayed Au 1.92 and Ag 0.82 oz./t. C is responsible for low recoveries by cyanidation. Amalgamation recovers 80% of the Au; followed by concentration a total recovery of 98.9% is obtained. In continuous operation, graphite coats the plates prohibitively. Floating an alkaline pulp with pine oil removes the graphite in a concentrate containing 22.56 oz. Au and 25.2 oz. Ag/t. This could be smelted. The tailing was easily cyanided to give 99% recovery of Au, a total of 98.9% by the 2 steps. AHE(30)

Report on the Treatment of Mixed (Bulk) Concentrate from Base Metal Sulphide Ore. W. E. Harris, R. J. Traill & H. C. Mabee. *Canada Department of Mines, Mines Branch Report* No. 720, 1931, pages 192–199.

A bulk concentrate analyzing Zn 29.89%, Cu 5.53%, Pb 3.44%, C 4.65%, Fe 19.39%, Au 0.16 oz. per ton and Ag 7.4 oz. per ton was roasted and leached. The liquors were neutralized to remove Fe, filtered, purified and electrolyzed. The residues were retreated by the Waelz process for volatilization of Zn and Pb. The residue from this step was a smelter product for the recovery of Cu, Ag and Au. Detailed data of each step are given. AHE(30)

REDUCTION METALLURGY (31)

New Facts on Blast Furnace Coke. (Neue Erkenntnisse zur Beurteilung von Hochofenskoks.) A. Killing. *Stahl und Eisen*, Vol. 51, July 16, 1931, pages 901–908.

Report 120 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. By tests running over several months, it was found that the use of coke made from finely ground coal (90% had a grain size of 0 to 3 mm.) decreases the fuel consumption in producing Thomas pig iron. This coke possessed a high porosity and it is assumed that any type of blast furnace coke should have a high porosity, provided it also has proper strength. GN(31)

Composition of Gas at Different Zones in the Blast Furnace, and the Theory of Mathesius. (La composition des gaz aux différentes zones du haut fourneau et la théorie de Mathésius.) A. Lefebvre. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 25–28.

Samples of gas were taken a few centimeters from the wall of a 250-ton blast furnace at 4 different heights. Two samples at each station were analyzed and the results averaged. The total $CO + CO_2$ remained practically constant but the ratio CO_2: CO increased steadily from tuyères to throat. A constant amount of 0.40% O_2 was found in all samples. HWG(31)

Modern American Metallurgical Practice. W. D. Jones. *Bulletin Institution of Mining & Metallurgy* No. 322, July 1931, 9 pages.

Brief notes are given on the East Helena, Mont., plant of the Anaconda Copper Mining Co., the Kellogg, Id., plant of the Bunker Hill and Sullivan Co., the Garfield, Utah and Omaha, Neb., plants of the American Smelting and Refining Co., and the Tooele, Utah, plant of the International Smelting Co. Sintering Minnesota Iron Ore at the Evergreen Plant. A. H. Hubbell. *Engineering & Mining Journal*, Vol. 132, Sept. 28, 1931, pages 244–247.

Technical details incidental to the design and operation of the largest sintering machine in the world, at Crosby, Minn., are given. The flowsheet for the plant is shown. WHB(31)

The Reduction Characteristic of Some Iron Ores. (Reduktionscharakteristik einiger Eisenerze.) J. KLARDING. *Archiv für Eisenhüttenwesen*, Vol. 5, Sept. 1931, pages 129–138.

The reduction of chemically pure iron oxide, various magnetites, siderites, minettes, limonites, purple ore and other iron ores was studied. After heating the finely powdered ores to 900° C. in vacuum, measured volumes of CO gradually reacted with the ores at that temperature. After the equilibrium had been established, the CO_2 content of the gas determined and the Fe-O content of the residue was calculated. The results were plotted in O_2 concentration curves in dependence on the CO_2 content of the gases after the test. In comparing these curves with the reduction curve of pure Fe_2O_3, conclusions can be reached as to the type and quantity of the impurities of the ores. Since the iron oxides form slags with the gangue present, the equilibrium lines of the ores must, of necessity, deviate from the equilibrium curve of the pure iron oxide. In relating the amount of the reduced Fe to the total Fe content of the ore, conclusions can be drawn as to the reduction capacity of the ores. The reduction curves show that the effect of the admixtures upon the reduction of the oxides of the ore is in part annulled. This finding will probably become of importance in the theory of burdening. The physico-chemical investigation of the O_2-reduction was completed by microscopic examinations. Such examination shows that, during the progress of reduction, new compounds or solid solutions are formed in solid state that can be studied qualitatively and quantitatively. GN(31)

Suggested Improvements in Fire Refining of Copper. H. H. ALEXANDER. *Engineering & Mining World*, Vol. 2, May 1931, pages 287–290.

See *Metals & Alloys*, Vol. 2, July 1931, page 138. (31)

The New Greenawaldt Sintering Plant at Kladno. (Die neue Greenawaldt-Sinteranlage in Kladno.) E. BAUMGARTNER. *Stahl und Eisen*, Vol. 51, Aug. 13, 1931, pages 1017–1021.

After dealing with the reasons for the installation of a Greenawaldt sintering plant at the Kladno iron works of the Prager Eisen-Industrie-Gesellschaft, the plant is described in detail and the practical results on capacity and costs are considered. GN(31)

The Flotation of Gold Ore. JOHN AGNEW. *Canadian Mining Journal*, Vol. 52, Aug. 1931, pages 710–711.

A description of the plant of Lake View and Star, Ltd., at Kalgoorlie, W. A. A flowsheet is included. WHB(31)

Retaining Dust in the Blast Furnace by Means of the Eichenberg Method. (Zurückhaltung des Gichtstaubs im Hochofen nach dem Eichenberg-Verfahren.) P. GEIMER, A. WAPENHEUSCH & A. SPONHEUER. *Stahl und Eisen*, Vol. 51, Aug. 27, 1931, pages 1073–1077.

The Eichenberg method injects gas and water through nozzles arranged around the throat of the blast furnace. By this method, the dust cannot escape and is deposited upon the burden. The gas temperature and its velocity is decreased through the evaporation of the water, thus also decreasing the amount of dust near the throat. Tests at the Hagen Blast Furnace Plant of the Klöckner Works indicate that it is not necessary to inject gas; however, the arrangement and the shape of the nozzles is of extreme importance. The amount of dust in the escaping gas could be decreased by 50% without affecting the operation of the furnace and the quality of the pig iron and the coke consumption unfavorably. Certain relations were found between the composition of the burden, the amount of dust and the effect of the Eichenberg method upon the fine dust content of the raw gas. GN(31)

Some Comments on the Height of Blast Furnaces. (Considérations sur la hauter des hauts-fourneaux.) E. COTEL. *Revue de Métallurgie*, Vol. 28, July 1931, pages 375–378.

The contemporary literature on blast furnace construction does not give a single fully justified reason for the necessity of an excessive height of the furnace. The increase of production can be controlled by the increase of the hearth diameter. The present height of the stack apparently does not bring any advantages but introduces many inconveniences caused by the depth of the burden and crushing of coke. Much information is available at present, both from theoretical considerations and furnace study, showing that the usual vertical dimensions of the blast furnaces can be reduced very considerably with beneficial results. JDG(31)

On the Reduction of Fe_2O_3 and FeO in Vacuum by Solid Carbon. (Ueber den Sauerstoffabbau des Eisenoxyds und des Eisenoxyduls mit festem Kohlenstoff im Vakuum.) W. BANKLOH & R. DURRER. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 455–460; *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 644–645.

Two conditions must be fulfilled in reducing iron oxides with solid C: (1) the mixture of reaction should not come in contact with air (O) since, in that case, CO is formed which is much more active than solid C; (2) the gases of reaction must be carried away as quickly as possible. In order to guarantee these 2 factors, the experiments were made in vacuum. Acheson and Bohemian graphite were used; other types could not be used because they always contained gases. In determining the O content of the reduced mixtures, the degree of reduction is established. Since previous investigators did not consider the phenomena of diffusion, this problem was particularly emphasized in this investigation. It is actually shown that the reduction of iron oxides by solid C is a simple reaction of diffusion, provided that the temperature of reaction is above 700° C. The formation of metallic iron starts at 700° C. Whereas FeO shows practically no reduction below 700° C. Fe_2O_3 reacts at still lower temperatures, down to 300°C., but no metallic iron is formed. It is possible that, in reducing Fe_2O_3 at the temperature range between 300 and 700° C., only Fe_3O_4 is formed up to a certain temperature and that above this temperature only FeO is formed. The Bohemian graphite reacted more readily than the Acheson graphite. GN(31)

Progress in Large Blast Furnace Construction. (Progrès techniques réalisés dans la construction des hauts fourneaux a grande production.) M. DERCLAYE. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th Session, Liege, June 1930, pages 29–48.

Includes discussion. Description and 14 illustrations of blast furnace details and accessories. HWG(31)

The Problem of Ore Dust Entrained by the Gases at the Throat of a Blast Furnace. (Quelques considérations au sujet des pousiéres de minerais entrainées per les gaz au guelard des Hauts fourneaux.) A. COUSIN. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June, 1930, pages 5–8.

Includes discussion. General comment on blast furnace design for work on ores that decrepitate. The dust ejected increases in parabolic relation to the velocity of the throat gases. A larger diameter and a different profile, for which reference should be made to the illustrations in the original article, are suggested to reduce gas velocity and separate the dust from the gases. HWG(31)

Lead Refining at the Bunker Hill Smelter of the Bunker Hill & Sullivan Mining & Concentrating Co. ALFRED F. BEASLEY. *Transactions American Institute Mining & Metallurgical Engineers*, 1930, pages 265–274

Includes discussion. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 51 (31)

Improvements in the Metallurgy of Quicksilver. L. H. DUSCHAK. *Transactions American Institute Mining & Metallurgical Engineers*, 1930, pages 283–298.

Includes discussion. See *Metals & Alloys*, Vol. 2, July 1931, page 139. (31)

Tin Industry of Yunnan, China. MARSHALL D. DRAPER. *Mining & Metallurgy*, Vol. 12, Apr. 1931, pages 178–186; May 1931, pages 242–247; *Mining Journal*, London, Vol. 173, May 23, 1931, page 415; May 30, 1931, pages 430–431; June 6, 1931, pages 452–453; June 13, 1931, page 472; June 20, 1931, pages 494–495; June 27, 1931, pages 509–510.

The occurrence of the ore, its mineralogy, concentration and smelting are described in detail. AHE(31)

Possibility of Improvement of the Blast Furnace. (Le possibilité de l'evolution du haut forneau.) V. DEFAYS. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th Session, Liege, June 1930, pages 49–54; *Chimie et Industrie*, Special Number, Mar. 1931, pages 504–510.

Speculations on possible improvements. HWG(31)

The Electric Blast Furnace Gas Purification Plant, System Lurgi, at the Lübeck Blast Furnace Plant. (Die elektrische Hochofengas-Reinigung, Bauart Lurgi, auf dem Hochofenwerk Lübeck.) J. DREHER. *Stahl und Eisen*, Vol. 51, May 7, 1931, pages 577–587.

Report No. 118 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. Construction, operation and practical results are considered. The purification plant is built for a capacity of 40,000 m.³/hr. and purifies the blast furnace gas in 2 steps. The dust is deposited partly in the pre-purifier and partly in the post-purifier which also acts as dryer. A gas cooler is installed between the 2 purifiers. This arrangement guarantees an economical purification and drying of the gas independent of the working of the blast furnace and its charge and also independent of the electrical, chemical and physical properties of the dust. The cost of this purification method is somewhat higher than that of other methods but is balanced by the better quality of the gas. In the discussion, the economics of the method were doubted by some speakers. GN(31)

The Dressing of the Copper Spar Products of the Mine Eisernhardter Tiefbau and the Additional Flotation. (Die Aufbereitung der Spatkupferprodukte der Grube Eisernhardter Tiefbau und ihre Ergängung durch die Flotation.) E. BIERBRAUER & H. GLEICHWURM. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 8, 1931, Report 178, pages 121–129; *Stahl und Eisen*, Vol. 51, July 16, 1931, page 917.

Since the previous dressing methods of the spathic ore mined by the above mentioned mine proved insufficient to fully separate its Cu content, a new additional flotation process was developed by this investigation. The ore contains Fe, 31.4%; Mn, 5.7%; Cu, 0.45%; residue, 18.7%. The new method which was developed gave excellent results. GN(31)

Mesothorium. G. MALCOLM DYSON. *Industrial Chemist*, Vol. 7, June 1931, pages 231–232.

Bibliography of 15 references given. There are 2 processes for the extraction of Th from the minerals which contain it, namely, the production of Th from "Th rich" minerals, in which the thorianite or similar mineral is powdered after hand sorting, heating to dryness with sulphuric acid, and the Th extracted with very dilute nitric acid; and the process for "Th poor" ores, which comprise the monazite sand series. A method for the latter is given in considerable detail. A brief discussion of the luminosity of mesothorium and the use of mesothorium in medicine is given. RAW(31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Application of Decorative Finishes to Crown Caps. F. J. GAVIN. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1057–1059.

Tin-plate and black-plate are the most widely used metals in this field; the metal generally is of the 65–107 lb. variety. The plate is cleaned and coated with a sanitary lacquer of gilsonite-China wood oil color varnish, which is baked in the automatic oven at 375–420° F. for 20–22 min. All outside coatings or lithographs must be water- and heat-resistant. Coatings for crown caps do not require a great degree of elasticity, so that the finish can be harder, thus increasing resistance to abrasion and pasteurization. MS(32)

Screw Cap Coatings. F. J. GAVIN. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 965–968.

Confined to caps for sealing foodstuffs and medicinals. Enamels used are usually combinations of TiO_2 or ZnO pigments ground in China wood or linseed oil containing resins. Lacquers consisting of gilsonite, resin, China wood oil mixtures are widely used. The sheet metal is thoroughly cleaned, and is then coated by means of a coating machine. For best results, thickness of individual films should not be more than 0.00035 in. Tests have shown that a finished coating 0.001 in. thick is 50 times more resistant to attack if this thickness is built up in 3 well baked coats of 0.00033 in. each than if applied in 1 coat. Enameling practice generally consists of applying 1 to 6 coats, depending upon severity of attack of material to be sealed. Baking temperatures for each coat vary from 150° F. for 1 hr. to 350-450° F. for 20–45 min. Baking is generally done in automatic ovens. The caps are then stamped and threaded from the coated sheets. The threading operation subjects the coating to severe stresses, thus often resulting in fracture and abrasion of the coating. This is true particularly of coatings on small diameter caps. Number of outside coats should be limited to as few as are necessary, as failures during threading are most often directly proportional to the number of outside coats. MS(32)

Economies in Lacquer Finishing. CARL E. BRETNEY. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 973–974.

Economies can be effected in the finishing of metal surfaces with lacquers through the use of colored lacquers which hide small defects in the metal surface, by using suitable drawing lubricant which is easily removed, and by the selection of suitable finishing equipment. MS(32)

Bituminous Pipe Coatings. RUSSELL R. BRANDT. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 799–801.

Natural asphalts, petroleum pitch, and coal-tar pitch are basic materials used in coatings for steel pipe to prevent corrosion. Coal tar primers are applied most satisfactorily by spraying. Bituminous coatings other than primer coats are usually applied by dipping into molten asphalt. Such coats are used to prevent soil corrosion. Pipe is also coated by wrapping with a felt cloth impregnated with bitumen. Asphalt emulsions are also finding application. MS(32)

Methods of Coating Steel Pipe to Prevent Corrosion. RUSSELL R. BRANDT. *Metal Cleaning & Finishing*, Vol. 2, Oct. 1930, pages 873–876.

Discusses commonly used methods of applying oil coatings to prevent corrosion. MS(32)

The Effect of Smelter Atmospheres on the Quality of Dry Process Enamels for Cast Iron. ANDREW I. ANDREWS & H. WILBUR ALEXANDER. *University of Illinois Bulletin* No. 227, May 19, 1931, 18 pages.

Except for the leadless Sn enamel, reducing atmospheres in the smelter were deleterious to all enamels tested. Metallic oxides are reduced, there is a loss of opacity and black spots appear on burning. Reducing atmospheres in the presence of high percentages of SO_2 were deleterious to all enamels tested. High lead enamels are least resistant. CHL(20)

PATENT DEPARTMENT

An arrangement with Mr. W. M. Corse, Metallurgical Engineer, Washington, D. C., who operates an Engineering Information Service, enables us to publish a list of important patents from the United States, Canada, England, Germany, France, Switzerland, Denmark, Holland, Sweden, Norway and Italy.

Copies of patents and translations will be supplied at reasonable cost. Patent searches made at minimum rates. Estimates cheerfully given.

Information about this service may be secured by writing to the Patent Department, METALS & ALLOYS, 810 Eighteenth Street, Washington, D. C.

United States Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process of treating ores of titanium containing chromium and recovering the sulphuric acid. N. Specht, 1,827,691, 4/6/29; Germany 4/14/28.
Torch. J. L. Anderson, 1,827,697, 10/5/29.
Mold lining. J. B. Grenagle, 1,827,742, 9/26/29.
Reduction of metallic compounds and production of arsenates. G. N. Kirsebom, 1,827,754, 7/18/28.
Treatment of cadmium-bearing material. G. N. Kirsebom, 1,827,755, 6/28/30.
Means for igniting ore. A. F. Beasley, 1,827,773, 10/21/29.
Ore sintering car. O. A. Oesterle, 1,827,799, 6/12/30.
Treatment of metals and/or their compounds. G. N. Kirsebom, 1,827,820, 5/29/29.
Process of making products with welded faces of stable surface alloy. P. A. E. Armstrong, 1,826,860, 1/16/24.
Proofing of metal against corrosion and particularly of iron and steel against rust. W. H. Cole, 1,826,866, 2/24/30; Great Britain 12/10/29.
Method of purifying ferrous metals. C. T. Hennig, 1,826,880, 8/22/28.
Purification of steel in the Bessemer process. C. T. Hennig, 1,826,881, 8/16/29.
Method of purifying steel in the open-hearth process. C. T. Hennig, 1,826,882, 8/16/29.
Process for the preparation of alumina. W. J. Müller, *et al.*, 1,826,895, 10/4/29; Austria 9/21/27.
Process of treating ores in the manufacture of rustless steel. C. Hart, 1,826,932, 9/26/30.
Electric soldering iron. R. R. Hazlett, *et al.*, 1,826,933, 3/12/30.
Apparatus for normalizing steel sheets. F. W. Pitts, 1,827,038, 1/28/29.
Furnace. F. A. Fahrenwald, 1,827,079, 9/16/27.
Process for the treatment of aluminum. M. K. de Trairup, 1,827,142, 12/4/29; Great Britain 9/3/29.
Methods of melting oxidizable material. C. Tama, 1,827,174, 6/10/29; Germany 6/16/28.
Tempering furnace. W. Grothe, 1,827,194, 8/27/28.
Method of protecting metal surfaces. S. R. Mason, 1,827,204, 10/18/27.
Method of welding. C. T. Siebs, 1,827,210, 12/4/28.
Treatment of iron and steel. C. M. Dennis, 1,827,223, 2/2/28.
Electric induction furnace. D. Willcox, 1,827,274, 8/13/28. Great Britain 9/8/27.
Reduction of metal compounds. G. N. Kirsebom, 1,827,821, 6/9/29; Sweden 5/14/29.
Rotatable furnace. R. C. Benner, *et al.*, 1,827,833, 12/7/28.
Apparatus for feeding electric furnace electrodes. J. G. Marshall, 1,827,852, 3/31/30.
Fine edged blade. (*Made of nitralloy.*) T. H. Frost, 1,827,870, 5/24/30.
Fine edged blade. T. H. Frost, 1,827,871, 11/10/30; 1,827,872, 11/14/30.
Process for the extraction of mercury from mercury-bearing ores or products. S. Croasdale, 1,827,971, 7/9/29.
Electrolytic cell curtain. L. E. Ward, 1,828,004, 6/10/29.
Curtain for electrolytic cells. L. E. Ward, 1,828,005, 7/29/29; 1,828,006, 7/29/29.
Process of heat treating. F. A. Fahrenwald, 1,828,036, 6/25/28.
Torch. A. J. Fausek, *et al.*, 1,828,135, 6/5/29.
Ingot mold and method of making same. J. E. Perry, 1,828,200, 12/16/26.
Press for sheet metal. C. J. Rhodes, 1,828,201, 4/30/29; Great Britain 2/15/29.
Blende sintering process. L. Boscheron, 1,828,241, 2/21/30; Belgium 3/9/29.
Method of making gears. (*By casting.*) E. E. Arnold, 1,828,271, 4/11/29.
Electric induction furnace. E. F. Northrup, 1,828,291, 11/23/29.
Process for the manufacture of rails with hardened heads. H. Kurz, 1,828,325, 7/7/28; Germany 8/22/27.
Centrifugal casting method. W. H. Millspaugh, 1,828,335, 4/26/29.
Manufacture of iron carbonyl. M. Müller-Cunradi, 1,828,376, 8/10/25; Germany 8/11/24.
Rolling mill installation. M. A. McCreary, 1,828,426, 4/14/30.
Roller spun metal manufacture. W. R. Harrison, 1,828,464, 5/19/28.
Method and machine for forming sheets. E. B. Carns, 1,828,489, 4/22/29.
Casting. W. G. Goodwin, 1,828,495, 9/10/28.
Shaft for heat-treating furnaces. J. Sammon, 1,828,510, 12/17/27.
Soldering cup. R. L. Bruce, 1,828,520, 11/2/29.
Manipulator for ingots, blooms and the like. J. D. Pugh, 1,828,619, 9/16/26.
Method of improving metals, and products thereof. E. S. Fisher, 1,828,701, 6/25/24.
Rotary kiln. (*For treating ores.*) J. Andrews, 1,828,727, 5/24/28.
Method of making partially lined bearings. J. Brincil, 1,828,731, 1/21/29, original 3/26/28.
Desulphurizing nickel-containing matte. A. S. Shoffstall, *et al.*, 1,828,752, 5/3/28.
Process for the refining of chromium ores. P. Weise, *et al.*, 1,828,756, 3/30/28, Germany 4/16/27.
Process of glazing refractory articles. G. S. Diamond, 1,828,767, 10/3/28.
Metallurgical furnace. F. A. Fahrenwald, 1,828,836, 6/17/29.
Heat-treatment chamber. W. A. Morton, *et al.*, 1,828,904, 2/5/28.
Wire drawing capstan. W. E. Carroll, 1,828,922, 7/13/29.
Method of annealing fusion welds. S. W. Miller, 1,828,977, 10/5/28.
Mold for casting refractories. F. W. Schroeder, 1,829,114, 7/9/20.
Process for the coating of metals upon cement surfaces. S. Seailles, *et al.*, 1,829,116, 9/25/24; France 9/29/23.
Process for making steel insensible to the action of hot gases and vapors. B. Strauss, 1,829,118, 11/18/26; Germany 4/1/26.
Metallurgical process. L. A. Wilson, 1,829,124, 11/11/27.
Rolling mill. E. G. Budd, 1,829,126, 2/23/28.
Metallurgical apparatus. A. P. Roux, 1,829,158, 6/28/29.
Metal concrete for hearth plates and the like. H. H. Harris, 1,829,218, 5/9/28, original (abandoned) 7/9/24.
Electric kiln. J. L. Merrill, 1,829,290, 6/5/29.
Means for charging blast furnaces and the like. C. M. Rutter, 1,829,300, 10/2/29.
Crucible furnace lining. H. E. White, 1,829,320, 1/3/29.
Process of rolling metal. M. C. Corrigan, *et al.*, 1,829,339, 7/17/29.

Tuyère. G. H. Hughes, 1,829,356, 7/15/30.
Control of temperature in electric furnaces and the like. A. G. Lobley, 1,829,-416, 9/22/26; Great Britain 10/1/25.
Reduction of ores, oxides and the like. H. E. Coley, 1,829,438, 1/5/31.
Electric soldering means. W. Schmidt, 1,829,457, 5/27/29.
Ingot turning machine. F. L. Sabin, 1,829,573, 9/18/26.
Blowpipe apparatus. F. C. Hasse, 1,829,592, 6/1/29.
Method and apparatus for cleaning sheet metal. H. E. McCrery, 1,829,599, 12/15/27.
Process of treating metals. (*Corrosion prevention.*) J. G. E. Wright, 1,829,-623, 11/16/29.
Method of making alloys. W. P. Davey, 1,829,635, 5/28/29.
Electrically welded jarred steel. A. G. Egler, 1,829,638, 1/13/31.
Aluminum alloy. W. Morrill, 1,829,668, 2/4/31.
Furnace. (*Furnace closure.*) N. R. Stansel, 1,829,684, 8/21/29.
Caustic bath. (*For removing enamel.*) M. W. Ward, 1,829,693, 9/29/30.
Prevention of corrosion in oil wells. J. C. Walker, 1,829,705, 3/12/25.
Carburizing and annealing furnace. A. D. Dauch, *et al.*, 1,829,710, 12/11/28.

Austrian Patents

Subject of Invention, Patentee, Patent No. and Date of Beginning of Term of Patent.

Method of removing blast-furnace throat dust from gas mains. Vereinigte Stahlwerke Akt.-Ges., 124,701, 5/15/31.
Process for producing pure iron. H. J. Van Royen, 124,687, 5/15/31.
Means for producing pipeless ingots. E. Bornand, *et al.*, 124,702, 5/15/31.
Contact elements for leading current into wire, strip, etc., which is being annealed. F. Krupp Akt.-Ges., 124,713, 5/15/31.
Process for electrolytically reducing the oxide layer of metal oxide rectifiers. Siemens-Schuckertwerke Akt.-Ges., 124,635, 5/15/31.
Device for lifting and depositing molds, particularly for interchangeable molds on casting machines. Soc. An. des Hauts-Fourneaux et Fonderies de Pont-à-Mousson, 124,769, 5/15/31.
Process for making chromium-aluminum alloys, using chromium-rich pre-alloys of aluminum. H. T. Tillquist, 124,697, 5/15/31.
Process for producing metallic magnesium by reduction of magnesium compounds with carbon in the electric arc. Oesterreichische-Amerikanische Magnesit Akt.-Ges., 124,696, 5/15/31.
Continuous process for pickling and annealing sheets. Copperized Steel Ltd., 124,685, 5/15/31.
Process for joining metal parts by soldering or welding. N. V. Philips' Gloeilampenfabrieken, 124,707, 5/15/31.
Process for treating rolled material, particularly wire or rod, prior to drawing. R. W. Moll, *et al.*, 124,710, 5/15/31.
Double-barreled lead press. Felten & Guilleaume Karlswerke Akt.-Ges., 124,681, 5/15/31.

British Patents

Subject of invention, Patentee, Patent No. and Filing Date.

Note: When the date given differs from that at which the application was lodged at the British Patent Office, the former date is given, followed by *.

Extrusion apparatus. Western Electric Co., Ltd., 356,758, 6/11/30*.
Testing of electrical and/or magnetic characteristics of metal sheets. Ferranti, Ltd., *et al.*, 356,690, 3/4/30.
Handling of furnace residues. T. G. Coghlan, 356,733, 4/22/29*.
Extrusion presses for metal rods, tubes and the like. Scovill Mfg. Co., 356,779, 4/7/30.
Manufacture of bent pipes or tubes. Stewarts & Lloyds, Ltd., *et al.*, 356,781, 4/14/30.
Cast iron article and method of manufacturing same. Ford Motor Co., Ltd., 356,795, 6/21/29*.
Production of a material more particularly for building and street structural purposes. Aluminiumerz Bergbau und Industrie Akt.-Ges., 356,797, 6/10/29*.
Lead calcium alloys for sheathing cables. Standard Telephones & Cables, Ltd., 356,801, 10/30/29*.
Apparatus for straightening rolled metal plates. W. Sykes, 356,842, 6/23/30.
Presses for drawing sheet metal and the like. Marquette Tool & Mfg. Co., 356,858, 7/8/30; 357,328, 7/29/30.
Feeding-device for delivering metal to the pots of type-casting and like machines. C. W. Hartmann, 356,863, 7/11/30.
Electric induction furnaces. Associated Electrical Industries, Ltd., 356,903, 8/14/29*.
Metal-working presses. F. J. Rode, 356,910, 8/18/30.
Device for feeding used stereotype plates into the melting-pot of a stereotype-casting machine. Machinenfabrik Winkler, Fallert, & Co., Akt.-Ges., 356,965, 10/24/29*.
Method of rolling sections having transverse ribs. H. Seiferth, 356,968, 12/19/29*.
Manufacture of tubes. A. Vollmer, 357,005, 2/8/30*.
Apparatus for taking samples of metal ingots slabs, or the like. United States Metals Refining Co., 357,025, 12/18/29*.
Crucibles for electrolysis of fused electrolytes. Siemens & Halske Akt.-Ges., 357,032, 12/23/30.
Furnace electrodes. Vereinigte Aluminium-Werke Akt.-Ges., 357,047, 1/23/30*.
Electric arc-welding. International General Electric Co., Inc., 357,062, 2/18/30*.
Cushioning device for sheet-metal drawing-presses. Marquette Tool & Mfg. Co., 357,182, 6/18/30.
Treatment of chromium-nickel-iron-carbon alloys. F. Krupp Akt.-Ges., 357,254, 6/24/29*.
Direct electric current arc-welding apparatus. J. B. Hansell, *et al.*, 357,308, 7/8/30; 358,138, 7/8/30.
Recovery of cobalt or compounds thereof. E. A. A. Grönwall, 357,366, 9/16/29*.
Mold for casting stereotype plates. C. Winkler, *et al.*, 357,382, 10/6/30.
Pickling of metals and the like processes. Imperial Chemical Industries, Ltd., 357,387, 10/9/29*.
Brass-melting apparatus. A. W. Machlet, 357,410, 11/10/30.
Process for protecting magnesium and magnesium alloys from attack by hot baths of saline melts. I. G. Farbenindustrie Akt.-Ges., 357,428, 12/11/29*.
Method of and weld-rod for electric arc-welding. A. O. Smith Corp., 357,512, 4/22/30.

Principles of Patent Law

for the chemical and metallurgical industries

By
A. W. Deller
Counsellor at Law
Patent Attorney
Chemical Engineer

About 500 Pages

Prepared as a practical working basis for the chemist and metallurgist to use in handling patent matters.

IN this book the author has filled a long felt need for an informative and authoritative work on patent law for those associated with the chemical and metallurgical industries and to explain complex legal doctrines of patent law in terms understandable to the technical man.

Metallurgists, Chemists, Research Directors, Managers and Executives of Metallurgical and Chemical enterprises will find in this book a a wealth of constructive and useful information and an abundance of detailed explanations of every phase of patent law, sufficient to meet their technical needs without being burdened with fine spun legal theories.

Some Subjects Dealt With

Classes of Patentable Inventions; Theory and Nature of Patents; Persons Entitled to Letters Patent; Principles of Patentability; Acquisition and Termination of Letters Patent; Remedy of Defective Patents; Form and Construction of Patents; Infringement of Letters Patent; Suits for Infringement; Incidents of Ownership of Patents; Commercial Phases of Patents; Foreign Patents.

Ready December 15th

$6.00

The* CHEMICAL CATALOG CO., *Inc.

419 Fourth Ave. New York, U. S. A.

Ingo strippers. E. J. George, *et al.*, 357,529, 4/23/30.
Process and method of manufacturing corrugated sheets. H. Syrowy, 357,559, 5/16/30.
Method of and means for the heat-treatment of metal. Wellman Smith Owen Engineering Corp., Ltd., *et al.*, 357,575, 5/21/30.
Manufacture of refractory articles. F. J. Tone, 357,611, 5/27/30.
Apparatus for electric arc-welding. G. Benedetto, 357,615, 5/28/30.
Salt bath for annealing metal articles. E. Fahrlander, 357,538, 6/19/30.
Manufacture of metals and alloys. May & Baker, Ltd., *et al.*, 357,539, & 357,540, 6/19/30.
Forging machines. Maschinenfabrik Hasenclever Akt.-Ges., *et al.*, 357,659, 7/2/30.
Alloys. Associated Electrical Industries, Ltd., 357,665, 7/5/29*.
Furnaces, crucibles and like heating appliances. Deutsche Gold-und Silber-Scheideanstalt Vorm. Roessler, 357,668, 7/8/29*.
Process for densifying the surface of cylindrical chill castings. J. Kleinewefers, *et al.*, 357,672, 7/15/29*.
Presses for drawing sheet metal and the like. F. J. Rode, 357,702, 7/29/30.
Die-casting machine. T. L. Allison, *et al.*, 357,711, 8/6/30.
Flask-handling devices for casting-machines. Sand Spun Patents Corp., 357,714, 8/8/30.
Method of manufacturing T-irons. O. Grave, 357,789, 9/29/30.
Aluminum alloys. H. W. Clarke, *et al.*, 357,800 & 357,805, 10/8/30 & 10/13/30.
Electric welding-machines. D. Sciaky, 357,852, 11/22/29*.
Method of and a machine for casting and forging. Ford Motor Co., Ltd., 357,855, 11/20/29*.
Method of treating cadmium-plated goods. C. T. Neal, 357,887, 12/23/30.
Method of producing mechanical autogenously-welded chains, rings or the like. F. Schull, *et al.*, 357,934, 3/17/30.
Three-high rolling mills. F. Krupp Grusonwerk Akt.-Ges., 357,939, 5/31/30*.
Magnetic materials. Deutsch-Atlantische Telegraphenges., 357,947, 3/24/30.
Alloy steels. Brown Bayley's Steel Works, 358,063, 3/27/30.
Electrical heating elements. G. Bray & Co., Ltd., *et al.*, 357,969 (Addition to 221,180), 4/30/30.
Process and apparatus for purifying zinc ore. O. Gerlach, 358,039, 5/27/30.
Anodes. Udylite Process Co., 357,977, 2/20/30*.
Apparatus for casting and trimming curved stereotype printing plates. H. Brown, 357,981, 6/30/30.
Valves for regenerative furnaces, heating apparatus and the like. S. Wohlfahrt, 358,257, 9/23/30.
Cupola furnaces. W. G. Gass, 358,267, 9/30/30.
Rolling mills for rolling metals. Emery Bros., Ltd., *et al.*, 358,291, 10/15/30.
Rotary drum furnaces. Firma: J. D. Brackelsberg, 358,352, 11/29/30.
Methods and devices for forming grids for accumulator plates by casting. Etablissements G. Briere, 358,357, 12/2/29*.
Method of and apparatus for casting metals and ceramic masses and other suitable materials by the centrifugal process. P. C. Fritzsche, 358,363, 12/9/30.
Casting molds for use in the manufacture of cast-iron socket pipes by centrifugal casting. F. Krupp Akt.-Ges., 358,365, 12/13/29*.
Manufacture of piping by extrusion. C. O. Evans, 358,379, 3/5/30*.

Canadian Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Furnace linings. (*Particles of silica in copper oxides.*) The American Smelting & Refining Co., 315,629, 5/28/30.
Furnace for roasting sulphide ore. The Complex Ores Recoveries Co., 315,661, 6/4/29.
Method of drawing hollow articles from sheets of magnesium and alloys. I. G. Farbenindustrie Akt.-Ges., 315,672, 9/27/29.
High grade magnesium alloy. Same patentee, 315,675 & 315,676, 11/11/30.
Process of forming iron alloy articles. The General Reduction Co., 315,700, 6/26/30.
Ore slag processing. La Soc. An. pour le Traitement des Minerais Alumino-Potassiques, 315,748, 1/13/31.
Process and apparatus for electrically forging iron and steel bars. La Soc. Holding de Brevets et Procèdès Giacchino pour l'Ebauchage Electrique S. A., 315,750, 8/18/28.
Magnetic structure. The Western Electric Co., 315,757, 4/22/29.
Alloy. (*Silver nodule material from electrolytic copper refining.*) H. M. Frederikssen, 315,801, 9/8/30.
Molding machine. E. Leyóndre, 315,810, 8/26/29.
Process of treating metallic oxides by hydrocarbons. A. Moreschi, 315,812, 5/3/28.
Die casting machine. The A. C. Spark Plug Co., 315,844, 3/14/29.
Process of making self-baking electrodes. Det Norske A/S for elektrokemisk Industri of Norway, 315,898, 12/6/28.
Stain resisting wrought article. (*Fe-Cr-Mn-C.*) The Electro Metallurgical Co. of Canada, Ltd., 315,911, 9/26/30.
Stain resisting wrought article. (*Fe-Cr-Mn-Cu-C.*) Same patentee, 315,912, 9/26/30.
Stain resisting cobalt alloy. (*Fe-Cr-Mn-Co-C.*) Same patentee, 315,913, 9/26/30.
Corrosion resistant article. (*Resistant to hot sulphurous gases.*) Same patentee, 315,914, 9/26/30.
Alloy. (*Fe-Cr-Mn-Mo.*) Same patentee, 315,915, 9/26/30.
Method of shaping metallic bodies. The Firth-Sterling Steel Co , 315,923, 5/16/30.
Carbon-free metal. (*Castings containing nickel.*) The International Nickel Co., Inc., 315,941, 11/10/27.
Zinciferrous material reduction. The New Jersey Zinc Co., 315,951, 12/15/30.
Electric resistance (Zr base). The Radio Corp. of America, 315,963, 12/9/29.
Light metal alloy. (*Al-Mg-Mn.*) P. Pritchard, *et al.*, 315,992, 1/24/31.
Annealing furnace. J. R. Garner, *et al.*, 316,010, 10/31/30.
Process of treating ores. E. J. Kohlmeyer, *et al.*, 316,014, 12/11/30.
Process of tempering metals. S. Marciniak, 316,062, 10/8/30.
Machine for pressing nuts from balls. W. Nussbaum, 316,068, 2/11/30.
Alloys for the manufacture of edge tools. (*Fe-Cr-Mn-C.*) A. E. G. T. von Vegesack, 316,081, 6/5/30.
Alloy. (*Cr group metals, nitrides thereof & lower melting metal.*) R. R. Walter, 316,084, 5/12/28.
Metal composition. (*Tungsten nitride, Co and Cr-group metal.*) R. R. Walter, 316,085, 8/25/28.
Tin recovery from scrap tinned metal. The African Tin Recovery Co., Ltd., 316,087, 12/26/30.
Copper melting furnace. The American Metal Co., Ltd., 316,088, 7/9/30.
Chain casting and repairing apparatus. The Moline Malleable Iron Co., 316,134, 11/28/30.

Danish Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Process and machine for casting molten metal under pressure. R. H. V. Christensen, *et al.*, 44,494, 1/7/30.
Metallic mold for die- or pressure-casting. Same patentees, 44,494, 4/7/30.
Refining cupola. P. Marx, 44,498 (2nd addition to 42,576), 12/22/30.
Metal tubing and other objects for high-temperature service. H. G. A. von Kantzow, 44,525, 9/16/30.

French Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Electric salt bath furnace. A. G. E. Hultgren, 712,063, 2/25/31.
Nickel alloy. Siemens & Halske Akt.-Ges., 712,076, 2/25/31.
Process for making iron and steel. Hirsch, Kupfer und Messingwerke Akt.-Ges., 712,194, 2/26/31.
Apparatus and processes for annealing metals without oxidation. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 712,236, 2/27/31.
Process for welding aluminum. M. Navarro, 712,030, 2/24/31.
New welding process. R. Sarazin, 712,152, 12/19/30.
Improvements to electric resistance furnaces. W. S. Smith, *et al.*, 712,082, 2/25/31.
Process for making steel ingots which are free from defects, and means for working this process. J. K. Hruska, 713,042, 3/11/31.
Process for making alloys, and tools made of these alloys. Fansteel Products Co., Inc., 713,086, 3/11/31.
Alloys of refractory metals, and tools made of these alloys. Same patentee, 713,087, 3/11/31.
Alloys of cobalt and molybdenum. Vereinigte Stahlwerke Akt.-Ges., 713,130, 3/12/31.
Improvements to machines for plugging tap holes. Mécanique Moderne & Anker Réunis, 713,156, 3/13/31.
Alloys of nickel and tin. Vereinigte Stahlwerke Akt.-Ges., 713,193, 3/13/31.
Process for making acid-resistant iron. Bamag-Meguin Akt.-Ges., 713,198, 3/13/31.
Process for improving inoxidizable steels. Soc. An. des Aciéries & Forges de Firminy, 713,221, 3/14/31.
Process for making alloys. Same patentee, 713,225, 3/14/31.
Alloys of nickel and molybdenum. Vereinigte Stahlwerke Akt.-Ges., 713,233, 3/14/31.
Process for producing iron having a high silicon content. Bamag-Meguin Akt.-Ges., 713,240, 3/14/31.
Alloys for making high-strength brasses. A. E. Le Thomas, 713,253, 3/16/31.
Production of very hard alloys. Vereinigte Stalhwerke Akt.-Ges., 713,358, 3/16/31.
Steel or cast iron having only slight tendency to rust. Vereinigte Stahlwerke Akt.-Ges., Addition 39,431 (1st addition to 695,398, 5/10/30), 11/28/30.
Cupola. P. Marx, Addition 39,485 (2nd addition to 663,942, 11/14/28), 12/26/30.
Process and apparatus for producing thin metal films. Electrical Research Products, Inc., 713,027, 3/11/31.
Process and machine for making tubes. L. Hinkel, *et al.*, 713,041, 3/11/31.
Process for cleaning metal surfaces. J. H. Gravell, 713,060, 3/11/31.
Process for making objects of thin metal, and objects made by this process. Driver Harris, 713,167, 3/13/31.
Process for rolling sheet zinc. F. Jordan, 713,181, 3/13/31.
Process for pickling inoxidizable steels. Soc. An. des Aciéries & Forges de Firminy, 713,219, & 713,220, 3/14/31.
Equipment for welding thin sheets. Fried. Krupp Akt.-Ges., 713,223, 3/14/31.
Improvements to extrusion presses. Imperial Chemical Industries, Ltd., 713,344, 3/16/31.
Process for making autogenously welded chains. Krafft & Schull, 713,371, 3/16/31.
Transformer coil coupling for welding machines. C. E. J. Brandt, 713,392, 3/17/31.
Automatic contact breaker for welding machines. C. E. J. Brandt, 713,393, 3/17/31.
Process and apparatus for casting metals and ceramic masses by centrifugal force. C. Fritzsche. Addition 39,477 (1st addition to 687,459, 12/-31/29), 12/19/30.
Improvements to polyphase induction furnaces. Soc. Générale d'Applications Electro-Thermiques, 713,294, 6/24/30.
Process for attaching a tool element or tip of refractory metal to a part or holder of ordinary metal. Fansteel Products Co., Inc., 713,474, 3/18/31.
Metal-working tool and process for making it. Same patentee, 713,475, 3/18/31.
Alloys of cobalt and tungsten. Vereinigte Stahlwerke Akt.-Ges., 713,428, 3/17/31.
Non-magnetic steel. Fried. Krupp Akt.-Ges., 713,445, 3/18/31.
Process for decomposing minerals containing lithium. Metallges. Akt.-Ges., 713,446, 3/18/31.
Process for preparing alloys. American Smelting & Refining Co., 713,550, 3/19/31.
Antifriction metal compositions. S. & T. Metal Co., 713,603, 3/20/31.
Improved aluminum alloys. Rolls-Royce, Ltd., 713,604, 3/20/31.
Cooling means for dissipating the heat produced during brazing or welding objects, particularly conductor cables. Allgemeine Elektricitäts Gesellschaft, 713,473, 3/18/31.
Improvements in the manufacture of tubes, particularly those for the transmission of heat. W. J. Still, 713,477, 3/18/31.
Rolling process. H. Seiferth, 713,597, 3/20/31.
Machine for drawing tubing. Demag Akt.-Ges., 713,680, 3/23/31.
Rolling mill roll and process for making the same. L. Quincy, 713,706, 3/23/31.
Improvements to electric induction furnaces. E. F. Northrup, 713,498, 3/18/31.
Machine for lining with antifriction metal. Bohn Aluminum & Brass Corp., 714,060, 3/30/31.
Process for welding scrap iron together, avoiding burning. Th. Goldschmidt Akt.-Ges., 713,799, 3/24/31.

Process for making chrome-nickel alloys. The General Electric Co., Ltd., 713,807, 3/24/31.

Production of chromium and its alloys with other metals, particularly nickel and similar metals. Same patentee, 713,808, 3/24/31.

Method and means for cooling materials annealed in pots. Felten & Guilleaume Carlswerk Akt.-Ges., 713,837, 3/25/31.

Process for refining metals. American Smelting & Refining Co., 713,916, 3/26/31.

Improvements to processes for brazing. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 713,751, 3/20/31.

Process for welding with the aid of chemically and electrically produced heat and welding rod for working this process. Soc. An. de Ateliers de Secheron, 713,860, 3/25/31.

Improvements to lead presses. Electric Hose & Rubber Co., 713,935, 3/27/31.

Tilter for rolling mills. Fried. Krupp Grusonwerk Akt.-Ges., 714,030, 3/30/31.

Process and apparatus for examining materials with X-rays. N. V. Philips' Gloeilampenfabrieken, 713,854, 3/25/31.

Electric resistance furnace. E. F. Russ, 713,789, 3/24/31.

Process for treating ores and other materials in the electric furnace. A. H. C. Deacon, 714,328, 7/12/30.

Copper ingots for rolling and process for producing the same. Anaconda Copper Mining Co. Addition 39,551 (1st addition to 635,865, 6/11/27), 12/15/30.

Process for treating iron baths in steel furnaces. Fried. Krupp Akt.-Ges., Friedrich Alfred Hütte. Addition 39,552 (1st addition to 80,154, 8/10/29), 12/16/30.

Process for making objects of phosphorous steel and objects made by this process. Vereinigte Stahlwerke Akt.-Ges., 714,068, 3/30/31.

Improvements to atomic-gas blowpipes. Cie. Française pour l'Exploitation des Procédés Thomson-Houston, 714,147, 4/1/31.

Method of assuring the tightness of joints made by welding metal sheets together. Soc. Nouvelle de Métallisation, 714,258, 7/3/30.

Process and machine for making hollow bodies, particularly tubing, by drawing around a mandrel. Metallges. Akt.-Ges., 714,271, 7/7/30.

Improved device for the automatic doubling of ovals in rolling mills. Soc. des Forges de Chatillon, Commentry & Neuves-Maisons, 714,290, 7/9/30.

Process for protecting articles of magnesium and its alloys. Soc. Continentale Parker, 714,321, 7/12/30.

Process for making metal sections. H. Seiferth. Addition 39,540 (1st addition to 689,116, 1/30/30), 12/10/30.

Process for heating by induction and furnaces using this process. Ugine-Infra, 714,246, 7/1/30.

Process for preventing contamination of the atmosphere of rooms containing electrolytic cells, and materials used for this purpose. Anaconda Copper Mining Co. Addition 39,569 (1st addition to 690,437, 2/22/30), 1/5/31.

Process for preparing a metal in very finely divided form and product made therewith. Soc. l'Auxiliaire des Chemins de Fer & de l'Industrie, 714,264, 7/4/30.

Process for reducing tin, particularly from material containing or not containing zinc or other metals. Berzelius Metallhütten G. m. b. H., 714,588, 3/31/31.

Three-high rolling mill. Fried. Krupp Grusonwerk Akt.-Ges., 714,609, 4/2/31.

Process for purifying the molten fluxes used in the production of light metals. Soc. d'Electrochimie d'Electrométallurgie et des Aciéries Electriques d'Ugine, 714,702, 8/5/30.

Process for making sponge metal. E. G. T. Gustafsson, 714,459, 3/5/31.

Improvements to machines for making elements or lattices of expanded metal. Kalman Steel Co., 714,467, 3/7/31.

Process for making blow-hole-free metal castings, especially of magnesium alloys, by introducing hydrogen into the molten metal. P. D. Brenna, 714,473, 3/10/31.

Process for making foundry cores. Imperial Chemical Industries, Ltd., 714,575, 3/28/31.

Process for welding tubing. H. Trunkwalter, 714,613, 4/2/31.

Aluminum conduit. A. C. Becker, 714,623, 4/2/31.

Method and means for stamping forgings by rolling. Soc. des Forges et Aciéries de Commercy, 714,651, 7/29/30.

Device for facilitating placing the blank and for increasing the useful work and rapidity of the operations in heavy-duty draw-presses. Schneider & Co., 714,703, 8/5/30.

Improvements to tunnel furnaces. Woodall-Duckham (1920), Ltd., *et al.*, 714,439, 2/26/31.

Alloys capable of being forged and hardened. Vereinigte Stahlwerke Akt.-Ges., 714,829, 4/4/31.

Electric furnace for annealing metal strip, wire, sheet or small objects. Otto Junker G. m. b. H., 714,865, 1/13/31.

Automatic arc welding machine. R. Sarazin, 714,709, 4/2/31.

Die holder for presses for sheathing submarine cables. Fried. Krupp Grusonwerk Akt.-Ges., 714,733, 4/3/31.

Improvements to machines for straightening rods and tubing. T. W. Hartley, 714,818, 4/4/31.

Apparatus for bending tubing and the like. G. L. P. Oger, 714,896, 4/7/31.

Articles which are resistant to the action of molten metals. Fried. Krupp Akt.-Ges., 714,938, 4/8/31.

Improvements to copper cooling valves made by forcing a blank through a die. Thompson Products, Inc., 714,939, 4/8/31.

Radiologic installation, particularly for examining materials. N. V. Philips' Gloeilampenfabrieken, 714,828, 4/4/31.

Improvements to anodes and to processes for making them. The International Nickel Co., Inc., 714,869, 3/11/31.

Refractory lining for rotary furnaces. H. von Ferber, 714,982, 4/9/31.

Hard alloy for tools and instruments. Fried. Krupp Akt.-Ges., 715,148, 4/13/31.

Process for making metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 715,206, 4/14/31.

Driving spindle for rolling mills. Schloemann Akt.-Ges., 715,207, 4/14/31.

Improvements to hard-metal compositions and to processes for making them. Cie. Française pour l'Exploitation des Procédés Thomson-Houston. Addition 39,595 (10th addition to 654,210, 4/4/28), 11/21/30.

Improvements to processes and apparatus for welding, and to the welded products. The Youngstown Sheet & Tube Co., 715,039, 4/9/31.

Improvements to welding apparatus. Same patentee, 715,078, 4/10/31.

Process for electroplating metals with alloys of copper and zinc. Firma Hille & Muller, 715,082, 4/10/31.

Process and mold for making ingots of finely granular structure and without pipes or blowholes. Vereinigte Aluminiumwerke Akt.-Ges., 715,226, 4/14/31.

Process for welding with a continuous-current arc derived from an alternating polyphase system. Firme Jean Nassheuer, 715,311, 4/15/31.

Soldering iron and a device for feeding the solder. F. Dupau, 715,321, 4/-15/31.

German Patents

Subject of Invention, Patentee, Patent No. and Filing Date.

Emergency switch for wire-drawing machines. R. Breitenbach, 534,718, 4/24/30.

Means for automatically stopping the blocks of wire-drawing machines. C. Rasch, 534,901, 9/13/29.

Press for making seamless lead pipe bends and the like. P. J. Wilbertz, 534,719, 8/30/27.

Rolling mill for the continuous production of transverse projections on metal rods and the like. H. Seiferth, 534,804, 6/28/29.

Rotary muffle furnace. Sachtleben Akt.-Ges., für Bergbau und chemische Industrie, 535,063 (Addition to 506,145), 10/24/26.

Process and means for melting masses of dust, particularly blast-furnace throat dust. A. Dawans, 534,727 (Addition to 506,350), 10/14/27.

Method of protecting metallurgical furnace walls containing magnesium orthosilicate. Metallges. Akt.-Ges., 534,820, 12/16/28.

Rotary drum for mixing molten metals and their alloys. Meier & Weichelt, 534,915, 12/14/28.

Process for making chromium steels. E. Herget, 534,989, 2/22/27.

Apparatus for heat treating objects made of steel and the like. C. W. St. J. Rowlandson, *et al.*, 534,821, 4/4/28.

Electrically operated discharge device for an electrical heating chamber for the local annealing of objects. Standard Elektrizitäts Ges., 534,822, 3/-13/27, U. S. 3/12/26.

Process for making hot cathodes, in which barium is deposited directly on the core wire by distillation. Siemens & Halske Akt.-Ges., 535,091, 5/26/28.

Induction melting furnace. E. Vits, 535,180, 12/4/30.

Warming device for molten-metal containers. Vereinigte Stahlwerke Akt.-Ges., 535,181, 12/4/29.

Apparatus for preparing molding sand. A. Lentz, 534,840, 12/20/27.

Mixing machine having a rotary stirring device, particularly for molding sand. A. B. Smith, *et al.*, 534,841, 3/11/30, Great Britain 3/22/29.

Nozzle brick. T. Brinkmann, 534,939 (Addition to 525,435), 11/15/29.

Process and apparatus for melting and casting under pressure. W. A. Loth, 535,182, 6/23/28; France 7/21/27.

Process and machine for making centrifugal castings composed of one or more layers. W. Raym, 534,842, 11/20/28.

Process and machine for making hollow centrifugal castings. Soc. An. des Hauts Fourneaux & Fonderies de Pont-à-Mousson, 534,843, 8/14/28.

Installation for make cores for pipes. R. Ardelt, 534,844, 2/27/29.

Foundry installation having two superposed conveyor belts. The Osborn Mfg. Co., 534,845, 1/14/30.

Self-gripping holder for specimens being tested for strength. Firma L. Schopper, 534,747, 11/26/29.

Process for making protective and resistant coatings. Siemens & Halske Akt.-Ges., 534,794, 12/10/26, U. S. 12/18/25.

Process for making highly refractory chromitic objects. A. Sprenger, 535,223, 10/11/27.

Shaft furnace for sintering, roasting and burning. Vereinigte Stahlwerke Akt.-Ges., 534,963, 11/7/29.

Cooling bed having a plurality of runways. Demag Akt.-Ges., 535,453, 9/27/30.

Press for extruding metals. E. Röber, 535,334, 12/2/28.

Process for extruding a non-cylindrical lead sheath around cables or for extruding non-cylindrical pipes of lead and the like. Socaso Akt.-Ges., 535,454, 3/27/30.

Device for making balls out of hot pieces of rod. R. Bigge, 535,739, 11/8/29.

Roll for making sections having local depressions, elevations and the like. Vereinigte Stahlwerke Akt.-Ges., 535,740, 7/19/29.

Process for making metallic carbonyls. I. G. Farbenindustrie Akt.-Ges., 535,437, 9/18/28.

Device for removing and carrying off blast-furnace throat dust. Vereinigte Stahlwerke Akt.-Ges., 535,748 (Addition to 534,313), 12/12/29.

Process for making pure steel. H. Van Royen, 535,527, 12/16/26.

Method of working the Thomas (converter) process. W. Mathesius, 535,749, 9/27/28.

Process for making homogeneous titanium steel. W. Mathesius, *et al.*, 535,750, 3/17/29.

Method and means for cooling annealed material which is to be kept bright. H. Prüfert, 535,340, 3/23/28.

Heating and annealing furnace for sheets and plates. H. Bangert, 535,751, 7/15/30.

Electric arc-welding process. Kjellberg Elektroden & Maschinen G. m. b. H., 535,631, 11/8/28.

Molding machine having an endless conveyor belt for the flasks. J. H. Küster, 535,778, 6/6/29.

Electromagnetic holding device for patterns and flasks. G. Franksen, 535,286, 4/8/30.

Process for making foundry core binders. O. L. Beer, 535,561, 4/9/30.

Core for casting hollow rolls, made of annular pieces of refractory material. W. Studte, 535,779, 7/12/28.

Device for centering and securing the chaplets, in the molding of hollow castings. Buderus'sche Eisenwerke, 535,780, 8/17/29.

Machine for making thin-walled centrifugal-cast pipe. W. Bremicker, 535,562, 2/20/30.

Process and machine for making hollow centrifugal castings. Vereinigte Stahlwerke Akt.-Ges., 535,563, 11/4/27.

Pressure tank for devices for cleaning castings with a mixture of water and sand. Badische Maschinenfabrik & Eisengiesserei, 535,287, 10/24/30.

Process for working up ores and other metallic compounds by roasting, making use of fused salt. Gewerkschaft Gevenich, 535,394, 11/20/26.

Production of solutions containing gold and silver by dissolving these metals in solvents containing iodine. Chilesalpeter G. m. b. H., 535,294, 1/8/29.

Fine-grained eutectic aluminum casting alloy. Th. Goldschmidt Akt.-Ges., 535,345, 12/10/22.

Platinum alloy and process for improving the same. W. C. Heraeus G. m. b. H., 535,688, 2/18/28.

Process for the electrolytic production of magnesium. A. C. Jessup, 535,346, 7/16/26; France 7/29/25.

Machine for cleaning tin plate. J. H. Cole, 535,699, 2/13/30; Great Britain, 2/15/29.

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

1201 **Industrial Furnaces.**—The November issue of the "Stewart Melting Pot," sent out by the Chicago Flexible Shaft Company, contains a number of short articles on the heat treatment of steel, interspersed with pictures and descriptions of their forges, pots and furnaces.

1202 **Cleaning Castings.**—A folder describing their automatic return tumbling barrel has been sent out recently by N. Ransohoff, Inc., West 71st St., Cincinnati, Ohio. The equipment is illustrated.

1203 **Metal Lacquer.**—An attractive booklet prepared by E. I. DuPont de Nemours & Co. Inc., Wilmington, Del., is devoted to their clear lacquers for metal protection. It describes the tests to which these lacquers were subjected and the results which were obtained.

1204 **Roller Hearth Furnaces.**—Bulletin No. 318 of the W. S. Rockwell Co., 50 Church St., New York, gives technical information on physical factors affecting production of uniformly heat-treated products. The principles outlined are applicable to all products subject to heat-treatment in the metallurgical, ceramic and chemical industries.

1205 **Electrical Conductors.**—A new booklet sent out by the Aluminum Company of America, Pittsburgh, Pa., describes their "Channeluminum" electrical conductors. These conductors are formed of two structural channels placed to form a hollow square. Suggestions for the installation of the channels are given, together with diagrams and charts.

1206 **Flotation Reagents.**—A new booklet issued by the Hercules Powder Co., Wilmington, Del., describes the action of the various pine oils and terpene reagents in the flotation treatment of ores. Specifications of the various Hercules products used in flotation are listed.

1207 **Gears Made of Armor Plate.**—This 8-page booklet prepared by the International Nickel Co., New York, deals with the use of 5% nickel and "Krupp analysis" (nickelchrome) carburizing steels for motor truck gears and pinions, with special emphasis on methods of heat treatment and fabrication.

1208 **Electric Furnaces.**—The Process Engineering & Equipment Corp., 5 Falmouth St., Attleboro, Mass., has sent out a leaflet illustrating several special installations of their bright annealing furnaces. Another of their leaflets is devoted to bright silver soldering.

1209 **Polishing Machines.**—Catalog No. 1196 sent out by E. Leitz, Inc., New York, announces their one-spindle and two-spindle automatic metallographic polishing machines. Their new specimen holder is also described.

1210 **Pattern Aluminum.**—A folder prepared by the Niagara Falls Smelting & Refining Corp., Buffalo, N. Y., gives the composition of their various aluminum casting alloys, stressing their pattern aluminum. The Falls aluminum and alloy aluminum are available in ingots and shots as illustrated in the folder.

1211 **Conveying Equipment.**—In the new Wright No. 15 Condensed Catalog, each type of Wright hoisting and conveying equipment is briefly described. Among the types of equipment included in the catalog are: Hand Operated Chain Hoists, Trolleys, Trolley Hoists, Traveling Cranes, Jib Cranes and Electric Hoists. Copies may be obtained from the Wright Manufacturing Co., Bridgeport, Conn.

1212 **Valves.**—Stainless Steel valves manufactured by the Alloy Steel Products Co., 103 Clayton St., Boston, Mass., are built to withstand severe operating conditions of corrosion, oxidation, contamination and pressure. A leaflet describing them and giving the dimensions of the valves is available.

1213 **Copper.**—The October 1st issue of the Copper & Brass Research Association Bulletin, 25 Broadway, New York, features unusual applications of copper and its alloys. The bulletin is fully illustrated.

1214 **Galvanizing Equipment.**—A 39-page booklet compiled by the United Engineering & Foundry Co., Pittsburgh, Pa., covers the cardinal principles of sheet galvanizing and the necessary equipment for doing the work. The information is given in non-technical language.

1215 **Gas Furnaces.**—Several models of the Juthe gas furnaces are illustrated in a folder issued by the American Electric Furnace Co., Boston, Mass. A section plan of one of the furnaces is shown, its construction described and special features outlined.

1216 **Automatic Reversal of Open-Hearth Furnaces.**—Bulletin No. 841-Z of the Leeds & Northrup Co., Philadelphia, Pa., contains valuable information for those interested in the performance of their furnaces. Copies are available from the company.

1217 **Carborundum.**—An attractive little booklet, "The Romance of Carborundum," gives the story of the development of this manufactured abrasive. It is prepared by the Carborundum Co., Niagara Falls, N. Y. Another booklet by the same company is "Abrasives in the Service of Industry."

1218 **Refractory Cements.**—Performance Report RE-3, No. 40, of the Johns-Manville Corp., 292 Madison Ave., New York, covers the application and results obtained through the use of Super-Refractory Cement in Detroit electric furnaces at the McGill Metal Company's plant, Valparaiso, Ind. Every effort has been made to have this report correct in every detail.

1219 **Measuring Machines.**—The Zeiss Measuring Machines are sold in this country by George Scherr Co. Inc., 142 Liberty St., New York, and this company has sent out a booklet describing these machines and giving instructions for their use. It contains numerous illustrations and diagrams.

1220 **Fluxes.**—Krembs & Company, 669 W. Ohio St., Chicago, manufacture special fluxes for every metal that can be soft soldered, silver soldered, brazed, welded or spot welded, and have issued a leaflet listing and describing them.

1221 **Cadalyte.**—An attractive folder, "The Key to Lowest Possible Plating Costs," may be obtained from the Grasselli Chemical Co., 629 Euclid Ave., Cleveland, Ohio. It outlines the advantages of this process to the plater.

1222 **Pyrometers.**—Catalog No. 86 of the Leeds & Northrup Co., Philadelphia, describes the optical pyrometer method and illustrates various types of their optical pyrometers. One section of the catalog is devoted to the applications of these instruments. Catalog 87 of the same company is entitled "Potentiometer Pyrometers" and describes not only the instruments themselves but also accessories for them. Prices are given.

1223 **Eraydo Alloy.**—This new alloy of silver, copper and zinc is the invention of the employees of the Illinois Zinc Co., 332 S. Michigan Ave., Chicago, Ill. A booklet telling about it is available and the company will also furnish a sample of the alloy itself. It is particularly applicable to radios, being non-magnetic and non-corrosive.

1224 **Heat Treatment of Steels with Cyanides and Salts.**—An 80-page book published by the Roessler & Hasslacher Chemical Co., Niagara Falls, New York, gives information on the application and operation of cyanide baths for the low temperature nitriding of special alloy steels. An interesting booklet by the same company is "Trichlorethylene, Its Properties and Uses."

1225 **Rustless Iron.**—The Superior Steel Corporation, Pittsburgh, Pa., has prepared an attractive pamphlet on their chrome and nickel chrome iron alloys. Analyses and physical properties of these alloys are given, and illustrations of some uses to which they can be put are shown.

1226 **Galvanized Sheets.**—The American Zinc Institute, New York, has sent out a pamphlet which gives a brief outline of facts ascertained in their tests on various galvanized sheets and gives recommendations for obtaining galvanized roofing and siding sheets which will give superior service. Names of manufacturers licensed to produce "Zinc Institute Seal of Quality" sheets will be furnished on request.

1227 **Fahralloy.**—The story of Fahralloy and its many heat and corrosion resistant applications are given in a leaflet issued by the American Manganese Steel Co., Chicago Heights, Ill. The ten different grades of Fahralloy are described.

1228 **Heat Treating Furnaces.**—The new Ryan-Scully bulletin No. 15D describes and illustrates R-S standard electric rivet and small parts heating furnaces, type C for small parts heat treating, rivet and forge stock heating.

1229 **Sheet Rolling.**—The Wean Engineering Co. Inc., Warren, Ohio, has sent out reprints of an article, "Combination System for Sheet Rolling," which appeared in a recent issue of "Steel."

1230 **Silver Solder.**—Bulletin No. 3 of the Handy & Harman Co., 57 William St., New York, is devoted to the characteristics and uses of their silver solder. The same company has distributed copies of a reprint of an article on "Silver Solders," given by R. H. Leach before the American Society for Testing Materials.

1231 **Su Veneer.**—The Superior Steel Corp., Pittsburgh, Pa., has sent out a folder containing a sample of their Su Veneer, for use where solid rust resisting materials are not required. This Superior metal is said to be resistant to denting, scratching and corrosion and to be as strong and tough as steel.

1232 **Nickel Cast Iron News.**—The October issue of this publication of the International Nickel Co., 67 Wall St., New York, features an article on Walworth chrome nickel iron pipe. It also contains number 9 of their "Intimate Chats on Metallography."

1233 **Haynes Stellite.**—The first of a series of booklets embracing Haynes Stellite products, their uses and methods of application is entitled "Properties of Haynes Stellite." It is a 30-page loose-leaf pamphlet and is a very thorough discussion of this product.

1234 **Gas-Fired Carburizing Furnaces.**—A leaflet sent out recently by the Surface Combustion Co., Toledo, Ohio, discusses their counterflow carburizing furnaces from the standpoint of economy and efficiency. Performance data are given.

1235 **Tube-Turns.**—Data on the new series 1R fittings of the Tube-Turn line are given in a bulletin sent out by Tube-Turns, Inc., 1303 S. Shelby St., Louisville, Ky. The addition of this new series rounds out the line affording 45″ and 90″ elbows and 180″ return-type fittings for welding in sizes 3/4″ through 20″ and in virtually all the weights required by modern piping.

1236 **Carburizing.**—The Carbonal process for carburizing steels in the electric vertical carburizer is described in Bulletin 931 of the Hevi Duty Electric Co., Milwaukee, Wis. Cost data are given and the bulletin is profusely illustrated.

1237 **Arc Welding.**—Data Bulletin No. 15 of the Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa., gives methods of inspecting and testing welds.

1238 **Blowoff Equipment.**—The Permutit Co., 440 Fourth Ave., New York, has issued a pamphlet telling how to save fuel and improve steam quality with their blowoff equipment. Illustrations and diagrams are given. The same company has also prepared a number of leaflets on their electrochemical feed.

1239 **Cemented Tungsten Carbide.**—A 31-page booklet compiled by the Carborundum Co., Niagara Falls, N. Y., gives some information on grinding cemented tungsten carbide. A large part of the booklet is devoted to a description of the process. Another bulletin by this company is entitled "Carborundum and Aloxite Brand Wheels and Mounted Points for Portable Grinders."
